In the discussion which followed, Mr. Coen briefly described motor-bus operation in Cleveland. In connection with this subject Mr. Stearns stated that in most large cities there existed a demand for extension of lines when in most cases it was extremely difficult to justify the construction of either single or double track. It may be that motor buses or trackless trolleys will serve to solve this problem and develop the territory. In conclusion, he stated that the development of the trackless trolley was something that was probably more imminent than damage to the industry by the invasion of gasoline buses in congested districts. With the trackless trolley there would be no charge for maintenance of roadway, and the propulsion current would be taken from the trolley. Repairs to motors would be simplified by using motors substantially the same as those on the electric cars.

Upon request, A. P. Walker, Dubuque, Iowa, described a trackless trolley system in operation there. Upon motion it was decided to continue the subject of trackless trolleys next year.

FARES AND TRANSFERS

Fares and transfers was the subject of the committee report made by J. V. Sullivan, Chicago Surface Lines. A discussion of this report was led by Elmer E. Strong, New York. He objected to a registering fare box because it required two accounting machines on the car. Mr. Ching believed that a registering fare box was of very great advantage, since his experience indicated that they were accurate and gave very little difficulty. He also stated that he believed that to-day the fare box gives as good an opportunity to the dishonest conductor as the old system of fare collection. Yet with the honest conductor he believed the fare box formed an ideal system for fare collection. Mr. Ching also discussed the question of transfer issuing devices and bodily transfer of passengers in prepaid areas. The advantage of the latter form of transfer, namely, in prepaid areas, has aided in greatly reducing the number of paper transfers issued. This has become quite a problem since it entailed such tremendous detail in auditing. With the increase in number of paper transfers there is bound to be a proportionate increase in the abuse.

M. R. Boylan, Public Service Railway, stated that his Company had been using fare boxes for about six years. As he stated at the last convention the use of the locked box had been discontinued as it was cumbersome and expensive. The company has about 1500 registering fare boxes on the system. He stated that there is a decided advantage in the use of the fare box, which can get all of the fares. When locked boxes were put into use from one to three per cent more cash was in the box than appeared on the register. Conductors should have some kind of a voucher for every passenger. The company is equipping most of the two-fare lines with registering boxes, using extra registers for the extra fares. The conductors use identification checks where there are lap-overs.

Tickets comprise the principal fare collections on the city lines of Detroit, and these tickets are of different values. The company's problem, therefore, is to find a fare box that will satisfactorily receive and contain collections made up of cash and tickets. This, as Mr. Brooks understood it, was radically different from the situation in other cities. In his opinion the principle of the prepayment type of car has been demonstrated to be correct, but it has introduced problems of its own and one of these is that of fare collection by fare box. The Detroit United Railway has experimented with practically all of the devices offered. For Detroit conditions the lock box seems best suited, used in connection with an independent totalizing register. The company finds it impracticable to use more than one compartment box, and, so far, the use of such a box has been quite satisfactory. These boxes are removed at the carhouses at the end of the day's run and are replaced by an extra till so that the car is at all times ready for use. The boxes are opened by a representative of three departments, and the contents are placed in a portable vault and sent to the general cashier's office. The company has not found that the item of maintenance is excessive. It is experimenting with other devices but considers the use of the present device warranted from every viewpoint.

J. H. Wilson, Mobile, stated that the results with fare boxes have been satisfactory, but that there is trouble with the ticket receptacle. The expense on the boxes has been 22 cents per month for labor and 22 cents for repairs. The use of the boxes results in fewer accidents in collecting fares, for the conductor's hands are free to open and close doors. He hoped to see the ticket-counting mechanism perfected to prevent counterfeiting of metal tickets.

Mr. Boylan called attention to the desirability of devising some uniform method of collecting fares so that the manufacturers could produce a box which would meet all conditions. In the Public Service box there is one totalizer giving the commencing number and ending number. The conductor settles for the difference between these at the end of the day. This permits the simplification of the mechanism and construction of the box.

J. E. Duffy, New York State Railways, Syracuse, believes in fare boxes on prepayment cars but is trying out different types at present, hoping to determine which is best. An overhead register should be used in connection with locked or registering fare boxes. A fare should be registered for every passenger. While there have been some losses with the registering box these are overcome by the larger number of fares received. All conductors are not dishonest, and the honest conductor makes no objection to the fare box. The dishonest one is always trying to take advantage of any mechanical contrivance, but the fare box gets the fares that the honest conductor would otherwise have missed.

W. C. Callaghan, Helena Light & Railway Company, stated that he cannot see the necessity for fare boxes at present.

On motion of Mr. Collins, seconded by L. H. Palmer, the record prepared by Mr. Sullivan was accepted with thanks to him and his associates. President Brush then suggested the appointment of W. H. Collins as a member of the resolutions committee in place of C. B. Buchanan, who was not present. A motion to this effect was carried.

CHARACTER OF EMPLOYEES

The order of the program was then slightly changed and N. W. Bolen, Public Service Railway, read his paper on "Jobs for Real Men." This is abstracted elsewhere. W. H. Collins called attention to the importance of mental poise and ability to take responsibility.

J. E. Duffy, New York State Railways, stated that one of the most important qualifications is ability to handle employees entrusted to a man's charge. The superintendent of transportation must have the good-will of the men under him, but this does not mean that he should be lenient in discipline. When men know that he is honest and just they will feel that they have been dealt with properly no matter what difficulties arise in administering discipline. The specialization of the present age make conditions much more difficult for the transportation man than they were formerly.

J. J. Dempsey, Brooklyn Rapid Transit Company, stated that he is not sure whether the technically trained or college man is as well adapted to transportation work as one who is not so trained.

Mr. Dempsey said further that it is difficult to find technically-trained men who are willing to put in the long and irregular hours necessary. Experience in steam railroad work seems to be good training and country boys seem better for this work than those from large cities.

The report of the committee on uniform definitions was presented by Edward Dana, Boston Elevated Railway, in the absence of H. C. Donecker, chairman. This report is abstracted elsewhere in this issue. The report was accepted and referred back to the committee for further consideration during the coming year. The meeting then adjourned.

EAST BOSTON TUNNEL TOLL SITUATION

The proposed abolition of 1 cent tolls in the East Boston Tunnel appears to have narrowed itself down to a point where the bondholders have it in their power to determine whether or not the toll shall be abolished. If the owners of the tunnel bonds can be persuaded to waive part of their rights for a consideration, the toll will be discontinued. At present there are $5,293,000 tunnel bonds outstanding bearing interest at from 3 to 4 per cent. On the face of each bond is the stipulation that the whole amount of tolls collected from passengers in the tunnel shall be used to meet the principal and interest of the bonds. The city of Boston now proposes to ask the holders to waive this pledge, and in return the city will appropriate $125,000 a year to be added to the rental received from the Boston Elevated Railway for the use of the tunnel. This would provide the total interest requirements. It is anticipated that most of the bondholders will agree to the plan, which was approved by the voters at the January, 1914, election.

In the spring of 1848, one Joseph Curtis, of New York, asked the Common Council for permission to lay an experimental street car track in Broadway. The Council resolved "that the petition of Joseph Curtis for an endless rail track through Broadway be denied." Mr. Curtis sent a second application, in which he said: "When the owners of property in Broadway and the public at large shall become fully satisfied of its utility, they will become the petitioners, instead of your humble citizen." This time the Common Council granted the permission and made various remarks upon the venture.

Among others, it was stated: "The cars proposed by the projector are novel in many respects. They will seat but a single row of passengers and accommodate twenty-four persons at a time; the doors enter at the side. It is known that car bodies mounted upon two trucks and having a long space between them are more buoyant and ride more easily than those mounted upon a single truck. Mr. Curtis's car truck partakes of the quality of the former, and in addition is furnished with a series of India ruber springs to relieve concussion and increase its mellowness."

Thus was the ancestor of the straphanger given his first taste of "modern" street car transit.—*Wall Street Journal.*

YESTERDAY'S SESSION OF THE AMERICAN ASSOCIATION

Yesterday's session of the American Association was called to order at 2:20 p. m. by President Black.

The first order of business was the presentation of the report of the committee on relations with the Manufacturers' Association by C. L. Henry. Mr. Henry reported that there were several questions of importance but no definite action had been taken, so the committee simply reported progress.

The secretary then read a letter from Mr. Townley, chairman of the committee on electrolysis, reporting progress. This report appears elsewhere in this issue.

Arthur W. Brady then presented the report of the Anthony N. Brady medal committee. This report is published elsewhere.

The secretary then read the report of the committee on the company-section medal, recommending the award of the medal to Mr. Abendroth of the Milwaukee section. In Mr. Abendroth's absence the medal was given to Mr. Stearns for transmission to Mr. Abendroth.

Mr. Henry then presented the report of the committee on relations with company sections. This was followed by the report of the *Aera* advisory committee and by Mr. Bullock's paper on the "Aspects of Workmen's Compensation Laws." These reports and paper are published in abstract elsewhere.

A. D. B. Van Zandt, Detroit, said that the act in Michigan was different. The Supreme Court in that state had recently decided that the words "average," as used in the act and applied to wages, meant only the average number of days which the business warranted. Thus in mining, the year was only 200 days.

J. J. Burleigh, Public Service Railway, Newark, said that railway men could very well subscribe to the principle of compensation laws without committing themselves to any particular character of statute which might be forced on them, and he thought the duty of the railway managements was to protect their stockholders to the extent of resisting illegal demands. The New Jersey bill had been opposed by the manufacturers but not by any of the public utility companies. It provided an elective feature which automatically carried certain stipulated payments for specific periods, and more than 90 per cent of the company's employees had accepted this option. The law had not added materially to the company's financial burden, but this was because the company in the past had followed a very liberal welfare plan voluntarily. The New Jersey law fixed 50 per cent of the wages as a basis for weekly payments, and this he thought was wise. During the first year 2357 employee accident cases were reported. Of this number the company paid compensation or rendered medical service, or both, in 1302 cases. The remainder were trivial accidents which did not require attention. The total liability created by these cases during the year was $63,530. This was $9,804 more than the company might have been obliged to pay if it had literally followed the law, but it had construed the law liberally. He thought the existing New Jersey law was defective because it made no provision for a dependent parent of a son, who in death left no widow. This, he thought, should be corrected by an amendment. The law allows latitude to the company in carrying its own risk or insuring in a casualty company or protecting itself in any other way. He did not believe in the necessity of a state commission to administer this law.

C. L. S. Tingley, Philadelphia, then discussed the legal aspects of decisions that had recently been rendered in employers' liability cases in several States showing, among other things, that the words used in many statutes of this kind "arising out of and in the course of employment" had been construed broadly by the court so as even to include a case where an employee had been injured by an intoxicated fellow-worker. In conclusion Mr. Tingley urged the standardization of these state laws so far as was possible as it was inconvenient for interstate companies to operate under different laws.

Mr. Rosecrantz, Milwaukee, gave some particulars about the Wisconsin law. He spoke of one case where a conductor, having reached the end of the line and being anxious to finish his night's work and run the car back, took the controller and speeded the car up and ran into an open switch and swung off the car and was killed. The company contended that this death was not occasioned because of his employment. This contention was sustained in the Circuit Court and was not appealed.

THE REPORT OF THE COMMITTEE ON WAYS AND MEANS

Mr. Donecker then read the report of the committee on ways and means. This is published elsewhere in this issue. Following the report of committee on ways and means President Black called for an expression of opinion of Messrs. McCarter, Henry, Allen, McGraw, Beeler, Gaylord Thompson, Tod, Brush, Brady and General Harries, all of whom indorsed the committee's report most heartily. Before acting on the report however, President Black called for the report of the committee on changes in the constitution and by-laws which was presented by C. L. Henry, chairman. In its report this committee recommended only such revisions of the constitution and by-laws as were necessary to conform with the ways and means committees' recommendations for increased dues. The new schedule of dues was published on page 775 of the issue of this paper for Oct. 10. Upon motion both of these reports were unanimously approved.

REPORT OF COMMITTEE ON PUBLIC RELATIONS

Thomas N. McCarter, chairman of the committee on public relations, next read that committee's report. It is published on another page. Commenting on the report he stated that it was the intention of the committee to refrain from too much refinement of this subject but to present a code of principles upon which all members could stand and use as a creed of their business. Too long has the industry allowed the demagogue and his ilk to occupy the stage. The time has come when the association's work on the subject of public relations should not be confined to the sporadic stage, but all should go out and preach the gospel. In conclusion, Mr. McCarter tendered his personal services as one of the preachers of the gospel of public relations.

Mr. McGraw most heartily indorsed the suggestions of Mr. McCarter and stated that he felt sure that all member companies would indorse the report. If funds were not available at this time to pursue a comprehensive public relations policy, at least certain phases of the committee's report could be followed. He recommended that certain representative members be drafted and requested to prepare written addresses on the subject which could be presented to the public upon request. He also urged that if such a course was pursued, the addresses should be most carefully prepared and afterwards printed and judiciously distributed by all member companies as public information. This could be done at a very small cost. Moreover if the work of the public relations committee is to bear fruit, it is largely the duty of the individual railway companies to promulgate the work.

A. D. B. Van Zandt, Detroit, also heartily indorsed the work of the committee and suggested that since the subject was so big and so important it might be well to organize a public relations association, whose duty should include the assembling of data and information for the use of individual members in refuting false information printed in local newspapers.

President Black also emphasized the importance of this committee's report and urged that the code of principles be published and spread broadcast. Col. Harries concluded the discussion with his indorsement, and the report of the committee was unanimously adopted.

Other Business

On account of the unavoidable absence of Calvert Townley director Lackawanna & Wyoming Valley Railroad, his paper on "Electric Railway Securities from the Company's Standpoint" was read by Mr. Doolittle, director bureau of fare research of the association. This paper was received without discussion, following which Henry N. Staats presented the report of the committee on insurance in the absence of Mr. H. J. Davies, chairman and secretary of the Cleveland Railway Company. This report was received as information and the association was then adjourned until two o'clock Thursday afternoon.

WEDNESDAY MORNING SESSION ENGINEERING ASSOCIATION

The Wednesday morning session of the Engineering Association was called to order by President Hanna at 9:30 o'clock. Mr. Hanna opened the meeting with a reference to the standardization rules which had been adopted by the American Institute of Electrical Engineers after consultation with the Engineering Association. While the rules had been adopted by the institute too late to have the formal scrutiny and approval of the various standing committees of the Engineering Association they had been referred to those committees with the expectation that they would be formally approved in so far as they affected electric railways.

Report of Committee on Equipment

F. R. Phillips, chairman, then presented the report of the committee on equipment. The items in the report were considered separately, with action on each as follows:

The revision of specifications for heat-treated carbon steel axles, shafts, etc., was approved.

The recommendation of the committee that it be instructed to prepare a specification for gears and pinions was approved. The recommendation concerning proposed co-operation with a committee of the Master Car Builders' Association for the design of a new standard brass to meet the conditions of high-speed heavy electric traction was approved with the amendment that the committee be instructed also to co-operate with the heavy electric traction committee.

The recommendation of the standards committee that the general subject of car wiring with special reference to fire protection be referred to the next committee on equipment was approved.

The recommendation of the committee that the specification for solid wrought carbon steel wheels be adopted as a standard (as approved by the standards committee) was approved after the specification had been read section by section.

The next subject was that of specifications for air-brake hose. W. G. Gove, Brooklyn, as chairman of the committee on that subject, described the conditions such as short radii curves and carriage of oil from compressors which had developed the need for a special grade of electric railway hose.

For several years his company had tried to buy hose under the M. C. B. rules, but had never been entirely successful. It had for several years largely purchased one specific kind, and it was still doing so to a certain extent simply because the hose was satisfactory although very costly. The object of the specification was to secure a good article on a competitive basis. After some discussion the motion was made and adopted that the specifications be accepted as a recommended specification, with the further suggestion that the incoming committee consider the question of smaller sizes in hose.

The next subject was the "Lighting of Electric Street Cars," a paper on which had been prepared by L. M. Clark, Indianapolis, as Appendix C of the committee report. The discussion opened with an interchange of opinion on the influence of the ceiling color. H. H. Adams, Chicago, said that last winter he had changed the ceiling color from pea-green to light buff on certain new cars. He believed that the illumination had been improved 50 per cent by this change. Mr. Adams thought it desirable also to use say sixteen 23-watt lamps in preference to five 94-watt lamps, as a larger number of small units gave better distribution. Terrance Scullin, Cleveland, believed that the efficiency of the large lamps was so much greater that any distribution advantage to be gained from a smaller wattage lamp was lost in comparison. For this reason his company had come to the use of five 94-watt lamps in series with a spare lamp in case of failure of any one of the five.

W. G. Gove, comparing the Interborough Rapid Transit and New York Municipal car lighting, said that the 57-ft. N. Y. M. car with Soudan globes and three circuits of 56-watt lamps enjoyed as good lighting as the 50-ft. Interborough car with six circuits of 56-watt lamps. The difference was largely due to the fact that the Interborough car was finished in green up to the advertising space, while the N. Y. M. car was white to the top of the seat backs. The Interborough cars were now being changed to white enamel.

G. H. Stickney said the big factor was the protection of the eyes of the passengers from the glare of exposed bare filaments. It had come to his attention that an organization for civic betterment was planning a campaign against electric railways purely on account of this feature of car lighting. It would be more desirable for the railway interests to take the initiative for satisfactory lighting rather than be forced to it by public sentiment.

E. W. Holst, Bay State Street Railway, sent a communication emphasizing that large ultimate economies in car operation could be secured by replacing carbon lamps with Mazdas, especially when reflectors are used. His company had been experimenting with reflector equipments, and now had more than 100 cars lighted with 56-watt lamps so equipped. The general results coincided closely with those given in the report. His company's experiences had been reported in the technical press, notably the Electric Railway Journal of Sept. 28, 1912, and Dec. 20, 1913, and the *Street Railway Bulletin* May, 1914. The safety question introduced by the reflector had delayed his company more in the adoption of reflector lighting than any other factor. Among other objections, a fitter of 2¼ in., in suspending a glass reflector by means of a flange, was not considered safe practice. Finally, the manufacturers had been persuaded to make up reflectors and holders with 2¾-in. fitter, which size has a stronger reflector and the desired greater clearance for the use of heavier porcelain. To strengthen the reflector farther the company obtained holders having a metal collar extending down inside the reflector which was supported in such a way that it could not fall unless completely shattered. The holders now used have strong sockets, which are flexible, so that the lamps receive a less severe jar on railway crossings, etc., and are held so that they cannot work loose. The lamps are not so readily removed from the sockets, and, therefore, are less liable to be stolen. In conclusion, Mr. Holst recommended that the association standardize a 2¾-in. fitter for car lighting reflectors, and that it also prepare specifications for reflector and holder equipment to overcome some of the weaknesses which he believed existed in most of those now on the market.

Following Mr. Holst's letter, Mr. Scullin, with reference to Mr. Stickney's remarks about bare filaments, said that glare was overcome by the frosted lamp. As to falling shades, his company had had at least 8000 of them in use for the past two years without a single fall.

Upon motion the report on lighting was accepted.

Lightning protection was the subject next discussed, Mr. Palmer making the motion that the committees on equipment, power generation, distribution, electrolysis and block signals be instructed to consider the subject of lightning protection in its relation to car and line equipment.

C. H. Kelsay, Indianapolis, thought that so far as the traction circuits were concerned the main thing was the protection of the car. It would be a good plan to make a study of the different types of arresters as to relative efficiency.

William Roberts, Akron, believed that the question of protecting the car service or car equipment should be kept entirely distinct from that of protecting the stations and substations. The electrolytic arrester was taking satisfactory care of power houses and substations on both the high and low tension sides. He thought that where trouble had occurred the electrolytic arresters had not been properly charged. Such charging should be done preferably when the load was lightest. His company did the charging on its 22,000-volt system between 1 a. m. and 2 a. m.

Mr. Phillips, Pittsburgh, said that his company had tried some experiments on arresters with a static machine, but to no purpose. A charting of the Pittsburgh system as to places of greatest lightning trouble had disclosed some disquieting results and indicated the importance of such a study.

After the acceptance of Mr. Palmer's motion for a study of lightning protection by the five committees named, the report of the committee on equipment was accepted as a whole with thanks.

Buildings and Structures

The report of the committee on buildings and structures, which is abstracted elsewhere in this issue, was presented by the chairman, C. F. Bedwell. Referring to the form of contract, Mr. Bedwell said that its contents had been drawn from various sources and that it had been declared legal. C. R. Harte, New Haven, stated that the counsel of the Connecticut Company had also declared this form legal. On motion it was decided to suspend action on the standard form of contract until it has been considered by the committee on standards.

On motion the standard fire protection rules submitted by the committee were approved for submission to the standards committee as they had been approved during the past year by the National Fire Protection Association.

The next subject was that of powerhouse construction, Appendix C of the report. On motion this subject was ordered continued. In this connection, Mr. Roberts said that cognizance should be taken of the fact that substations are frequently a part of the modern power station.

On motion the report of the committee as a whole was accepted with thanks. The meeting was then adjourned.

ANNUAL MEETING OF MANUFACTURERS' ASSOCIATION

The annual meeting of the Manufacturers' Association was held yesterday afternoon in the Greek Temple. President Hawley introduced President Black, of the parent association, who extended the greetings of that association to the manufacturers. He also congratulated the Manufacturers' Association and thanked the committees for the important parts taken in convention endeavors.

President Black announced that the executive committee would call the mid-winter conference of the American Electric Railway Association and its allied associations in Washington. This city has been chosen instead of New York, because in New York practically no newspaper publicity wss obtained. In other cities, and particularly in Washington, the newspapers would feature the association deliberations and would distribute these by telegraph throughout the country. The next annual convention, he announced, would be at San Francisco. As a San Franciscan, President Black asked the hearty co-operation and support for the next convention. In closing he wished for a continuation of the harmonious working relations, happily now existing between the American and Manufacturers' Association.

President Hawley then announced the following nominating committee: W. L. Conwell, N. M. Hench, E. R. Mason, R. M. Campbell and E. F. Chaffee.

Before President Hawley instructed this committee, the association listened to Daniel M. Brady, who spoke of the desirability for having the executive committee include men from various sections of the country.

President Hawley announced that the location committee had seriously considered Boston for the 1914 convention, but that exhibit hall facilities were not available at the usual convention time. In connection with the present convention he reported a reduction of 5.5 per cent in exhibition space sold, as compared with last year. This year approximately 65,000 sq. ft. of space had been sold. The attendance of manufacturers was within 9 per cent of that at the same time last year, and the number of companies belonging to the association was practically the same.

When arrangements for this convention were made, no such serious financial conditions confronted the executives, or special means would have been taken to economize to even a greater extent than has been done this year. The cost of exhibition space this year was fixed at 35 cents per square foot, this being 12½ per cent less than that charged for the last two years. It was estimated that the surplus at the end of the present year would be practically the equal of that carried over last year. President Hawley spoke briefly of the 1915 convention and said that no special exhibit had been planned because a large number of the members would have permanent exhibits at the exposition.

In closing President Hawley said: "This convention is, I believe, considered a most satisfactory one, and the arrangements of the exhibits and the entertainment provided are fully equal to any of our previous conventions. Great credit is due to my associates on the executive committee, and particularly to the vice-presidents and chairman of the committees and their committeemen."

A unanimous vote of thanks was tendered to President Black for his co-operative efforts in connection with the present convention and exhibits. A unanimous vote of thanks was also extended to the officers and committees in charge of carrying out this year's exhibition. A motion thanking and complimenting Secretary-Treasurer McConnaughy for his large part of the convention work was passed unanimously.

The nominating committee then reported the following slate, for new members of the executive committee: E. F. Wickwire, Ohio Brass Company; John C. Jay, Pennsylvania Steel Company; Wiley Brown, Bridgeport Brass Company; C. R. Ellicott, Westinghouse Traction Brake Company; L. E. Gould, Electric Railway Journal. These nominations were received.

L. E. Parker then presented a separate ticket as follows: E. F. Wickwire, Ohio Brass Company; George Stanton, Cleveland Frog & Crossing Company; Thomas Aldcorn, Chicago Pneumatic Tool Company; W. F. Cutler, Southern Wheel Company; L. E. Gould, Electric Railway Journal.

The ballot resulted in the election of the following new members to the executive committee: Messrs. Wickwire, Stanton, Cutler, Ellicott and Gould.

According to the United States Geological Survey, the tungsten resources of this country are probably larger than has generally been realized. Many new deposits have been discovered in various parts of the Western States.

REPORT OF COMMITTEE ON OVERHEAD CHARGES

The purpose of the report of the committee on overhead charges, presented yesterday before the Accountants' Association, was to gather data as to the extent and nature of overhead charges as used by appraisers. Under the Interstate Commerce Commission system effective July 1, 1914, records of overhead charges as defined by appraisers cannot conveniently become a permanent part of the accounting procedure but must be provided as memoranda after the work is completed. Several member companies, however, have devised forms of unit cost analysis which not only permit compliance with the official classification but also provide authoritative data as to unit costs and overhead charges which will fortify their engineers in valuation proceedings before commissions.

The report mentions criticisms by appraising engineers of such items as stores expense, utility expense and equipment and tools embodied in last year's committee classification. If such items are definitely understood to be specific construction costs, the scope of the definition of overhead costs is correspondingly restricted, but such miscellaneous charges often continue to be presented to the accountant after the constructing engineer has completed his work. For this reason the committee did not think it advisable to change the details of its last year's classifications. Whether its defined overhead charges were included by appraisers in unit costs or as undistributed additions to the total of specific items was immaterial as long as such charges were not omitted or understated.

From the records of overhead costs submitted to the committee it was not possible at this time to make tabular comparisons covering all tangible and intangible overhead. The remainder of the report, however, was devoted to pointing out the magnitude of certain overhead items in the construction costs and the character of the charges included.

The main divisions discussed follow: Engineering, administration, stores expense, utility expense, labor expense, contractor's expense, equipment and tools, preliminary construction work, injuries and damages during construction, legal expense during construction, taxes during construction, insurance during construction, interest during construction, and unforeseen contingencies during construction. The specific data and percentages cited under each heading indicated the typical differences in amount which might be expected in any comparative analysis of overhead charges and led to the conclusion that no definite percentages could be designed which could be applied equitably to every case. Appraising engineers in making valuations must consider the differences that arise in particular cases. The committee stated that it was impressed with the necessity of accompanying appraisals with an analysis of actual available construction costs. The data collected by the committee was to be filed with the association and it was recommended that the work of preparing such additional memorandum records as might be submitted by member companies in accordance with the classification adopted be referred to the bureau of fare research during the ensuing year.

CONSTITUTIONAL RIGHTS

Some men think a nickel is a whole lot of money when they spend it on a street car company. It gives them the privilege of crossing their legs and letting people trip over them. It also gives them the right to sit sideways and look out of the window so they can occupy two seats. They regret the expenditure of the nickel so much that they economize by carrying the remains of a Flor de Glue Factory cigar into the car and take pleasure in holding it where others can inhale its fragrance.—*Cincinnati Enquirer.*

REPORT OF THE "AERA" ADVISORY COMMITTEE

The report of the *Aera* advisory committee, presented at the meeting of the American Association yesterday afternoon, explained that advertising was resumed with the January issue, and a gratifying increase has been shown in the number of manufacturing concerns which have used the pages of the magazine. With adverse business conditions and with the necessarily slow process of building up an advertising clientele, it has not yet been possible to place the magazine on a self-supporting basis, but the committee looks forward with confidence to a time in the very near future when the advertising receipts will more than pay the expenses of publication. Continuing, the report said, in part, as follows:

"The committee, at its first meeting, assigned to various members of the committee the work of securing contributions for *Aera's* pages. The result has been shown in the magazine from month to month. Vol. II of *Aera*, which ended with the July, 1914, issue, contained 1447 pages of reading matter as opposed to 1163 in Vol. I. Aside from the Question Box, 106 association members contributed articles. The Question Box has grown greatly in strength during the past year, 258 individuals contributing 1299 answers to 254 questions. These were divided by subjects as follows:

	Questions	Answers	Individual Contributors
Accounting	17	106	45
Way matters	40	325	72
Buildings and structures	1	5	5
Power generation	24	108	51
Power distribution	50	243	64
Equipment	31	195	57
Transportation	52	276	87
Miscellaneous	1	3	3
I. C. C. decisions	38	38	..
Total	254	1299	258

"*Aera* is intended to be a magazine for electric railway men by electric railway men, and the interest shown by association members is enabling it to fulfil the expectations of its founders.

"As a medium for putting the association members in touch with each other and with the work of the organization, your committee believes that the magazine has accomplished its purpose in a most satisfactory way. In the dissemination to electric railway men of information concerning the industry a great work has been and is being accomplished. Many able expositions of problems affecting the industry have been set forth in *Aera's* columns, and its influence has extended far beyond the limit set by the association membership. This influence has extended also through the use of a clipping service, sent to more than 1200 daily newspapers in the United States. The use of extracts from *Aera* has been quite general. Along the line of publicity may be cited work in connection with the convention. A full press service has been established to distribute information both before and during the convention, and the press associations have handled at gratifying length, considering the situation in respect to war news, the proceedings of the conventions.

"Your committee begs to extend its thanks to those who have contributed to *Aera's* pages and to bespeak for the magazine the continuance of the interest, which, in the committee's opinion, has established the success of the publication as a prominent feature of the American Electric Railway Association's work."

According to figures just made public by the Interstate Commerce Commission Eastern carriers operating 56,832 miles of road in August, 1914, as against 56,789 miles in August, 1913, made the following showing: Operating revenues, August, 1914, $117,009,576, against $124,764,032 in 1913; operating expenses, $79,018,045, against $87,756,902; net operating revenue, $37,991,551, against $37,007,130.

REPORT OF COMMITTEE ON EQUIPMENT

The committee on equipment of the Engineering Association reported yesterday on the several topics assigned to it as follows:

Revision of Specification for Heat-Treated Carbon Steel Axles, Shafts and Similar Parts—Owing to certain alleged unsatisfactory results by some users of axles under this standard specification and owing to the revised specification of the American Society for Testing Materials which was formerly nearly identical with that of the Engineering Association, the committee recommended that its successor be instructed to investigate the results obtained with axles made under the standard specification and to report on same with suggested revision, if any.

Specification for Gears and Pinions—The committee reported that it had gathered data on this subject and recommended continuation of the subject by the next committee.

M. C. B. Brass for High-Speed Heavy Electric Traction—The committee reported that Frank Kingsley, associate editor ELECTRIC RAILWAY JOURNAL, had drawn its attention to troubles experienced by heavy electric traction operators with the M. C. B. journal brass. The committee recommended that this subject be investigated by the Engineering Association in collaboration, if possible, with the Master Car Builders' Association.

Wires and Cables for Car Equipment—In this part of the report the suggestion is made that in many cases it would be found easier to draw the made-up cable into a straight run of soft steel conduit and afterward bend to form. This would be safer than bending the conduit and drawing the cable in afterward, and would enable a closer fit and less air space between cable and conduit to be attained. Lead-covered cable has many points in its favor, particularly easy installation, but care must be taken to avoid sharp bends and the driving of nails into it, and to support it against sagging. In general, the usefulness of lead-covered cable will be largely restricted to rewiring old cars since it costs more than steel conduit. The committee believed that a 30 per cent pure Para rubber was unnecessary for car wiring, but suggested that the manufacturers label each coil with an attested statement of the physical, chemical and electrical characteristics, the latter to include resistance in megohms per mile. A 20 per cent Para had been found satisfactory for 600-volt circuits, but an additional 1/32-in. diameter rubber insulation was recommended for 1200 to 1500-volt d.c. circuits. An extra flexible rubber-covered triple-braided flameproof cable was recommended for main motor leads to fulfil underwriters' requirements. As rubber compound is necessarily inflammable, the only way to make insulation flameproof is to inclose it in a flameproof casing or braiding. It would be well to demand that taping or braiding be treated chemically to make it non-inflammable, but at present a non-combustible cable or cable covering seems unattainable. Steel conduit was being used more widely but on no account should it be used for the length of cable from the trolley or conductor base to the lightning arrester and from the lightning arrester to ground owing to the impedance which it would offer to a discharge of lightning. This length should be protected by fireproofed and watertight hard-wood or fiber molding.

Specifications for Solid-Wrought Carbon-Steel Wheels—The committee reported that it had not been found expedient at this time to promulgate definite designs of tapes, gages and templets, since all makers and inspection engineers have such apparatus which can be easily adapted to the standard association wheel design. The changes in the wheel specification as reported last year, other than those in phraseology, were as follows:

1. Inclusion of chemical composition requirements for steel made by the acid process.
2. Increase in allowable variation in carbon content from six to ten points difference.
3. Division of tolerances into classes, based upon service which wheels are to enter instead of on method of finishing at the mill. These tolerances are arranged so that under the specification wheels will be furnished machined to minimum tolerances unless special arrangement is made to permit of the use of wider tolerances and of furnishing wheels with rim contours unmachined. It is expected that most of the wheels ordered under this specification will be manufactured under the wider tolerances, and with the option to the manufacturer of furnishing unmachined contours, the tolerances being so fixed that under all usual conditions of service wheels furnished under the larger tolerances will be sufficiently accurate for service conditions.

The committee believed that a specification had been produced which may be safely used and recommends the adoption of the same as standard.

Specification for Air-Brake Hose—The committee submitted a specification on this subject with the recommendation that it be adopted as a recommended specification. The matter of an oil-resisting inner tube where the hose is subject to oil from compressors was recommended for further study owing to the lack of data on this subject. The specification follows:

SPECIFICATION FOR AIR BRAKE HOSE

I—MANUFACTURE

Number of Ply—1 (*a*) The hose shall be not less than four ply, and shall be soft and pliable.

Grade of Material—1 (*b*) Only a high-grade quality of rubber and cotton fabric shall be used. Rubber substitutes or short fiber cotton will not be acceptable.

Sample for Test—1 (*c*) The manufacturer shall furnish, free of cost, one extra hose for test purposes, with each lot of 200 hose ordered.

II—PHYSICAL PROPERTIES AND TESTS

Porosity Test—2. For the purpose of determining the porosity of the inner tube, one hose will be selected at random from each lot of 200 ordered, and subjected to an air pressure of 140 lb. per sq. in. for a period of five minutes. At the end of this time the rubber cover will be split with a knife and the hose submerged in water.

Under this condition and with above air pressure still in the hose, the inner tube shall not show any porosity.

Any escape of air must be distinct enough so as to permit of readily distinguishing between that due to the air which may be confined within the structure of the hose and that due to the porosity of the inner tube.

Bursting Test—3 (*a*) One hose will be selected from each lot of 200 ordered and a section 5 in. long cut from one end. The remainder of hose will then be subjected to a hydraulic pressure of 200 lb. per sq. in., and under this pressure the hose shall not show any signs of leakage nor develop any defects and shall meet the following requirements:

3 (*b*) The maximum expansion on the circumference shall not exceed the following:

Nominal size of hose	⅞ in.	1¼ in.	1⅜ in.
Maximum expansion	½ in.	⅝ in.	¾ in.

3 (*c*) The hose must then withstand the following hydraulic pressures for a period of ten minutes:

Nominal size of hose................	⅞ in.	1¼ in.	1⅜ in.
Pressure, pounds per square inch....	750	600	500

Friction Test—4. A section 1 in. long will be taken from the 5-in. section previously cut off, and a 20-lb. weight suspended from a separated end of wrapper in such a manner that the force will be applied radially and uniformly, and the amount of unwinding under these conditions shall not exceed 8 in. in ten minutes.

Stretching Test—5 (*a*) Another section 1 in. long will be cut from the remainder of the 5-in. piece, and the rubber tube or lining will be separated from the ply and cut at the lap. Marks will be placed on this section 2 in. apart and then the section will be quickly stretched until the marks are

10 in. apart and immediately released. The section will then be remarked as at first and again stretched to 10 in. and held in this position for a period of ten minutes. It will then be released and when measured within thirty seconds of the time of releasing the distance between the marks last applied shall not exceed 2¼ in. At the end of ten minutes the distance between the marks will be again measured and the set at that time shall not exceed ⅛ in.

5 (*b*) Strips taken from the cover shall meet the same requirements as specified for the inner tube in Section 5 (*a*).

Tension Test—6 (*a*) The hose shall conform to the following requirements as to tensile strength:

	Pounds per Square Inch Minimum	Pounds per Square Inch Maximum
Inner tube	800	1200
Cover	700	1100

From the 3-in. section remaining after the friction, stretching and tensile tests are made, a strip of duck the entire length of this section will be taken. One piece will be cut 3 in. wide and parallel with the warp threads of the duck. Another piece will be cut 3 in. wide parallel with the filler threads. The tensile strength of each of these pieces shall be determined by the use of grips as shown in Fig. 1 placed 1 in. apart directly opposite one another on the center of the test section. The section thus tested must develop a tensile strength of at least 225 lb. per inch for both warp and filler threads. The rate of separation of the grips shall be approximately 20 in. per minute, and in no case shall the test be counted when the duck breaks in the grips.

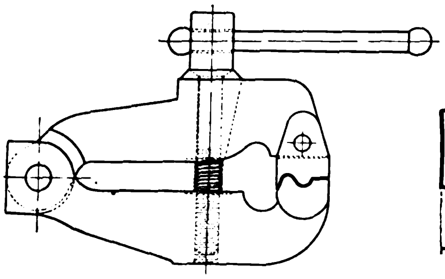

FIG. 1—GRIP FOR TESTING DUCK

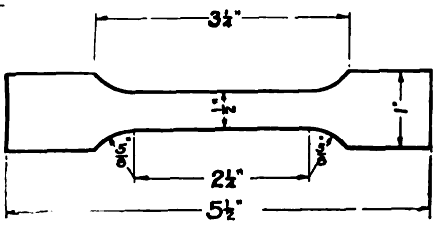

FIG. 2—TENSION TEST SPECIMEN FOR RUBBER

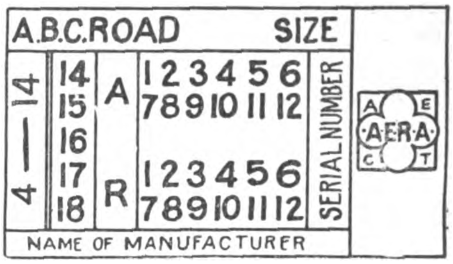

FIG. 3—HOSE LABEL

(*b*) Tension test specimens shall be taken from each lot of 200 ordered.

(*c*) Tension test specimens from tube and cover shall be cut with a specially designed die of the dimensions shown in Fig. 2.

III—SIZE AND DIMENSIONS

7. The hose shall be smooth and regular in size throughout its entire length, and shall conform to the following sizes:

Dimensions	Nominal size ⅞ in. Maximum	⅞ in. Minimum	1⅛ in. Maximum	1⅛ in. Minimum	1½ in. Maximum	1½ in. Minimum
Length	Specified length	½ in. under that specified	Specified length	½ in. under that specified	Specified length	½ in. under that specified
Outside diameter.	1-5/8	1-9/16	1-7/8	1-13/16	2-1/8	2-1/16
Inside diameter ..	15/16	7/8	1-3/16	1-1½	1-7/16	1-3/8
Thickness of cap vulcanized on ..	3/32	1/32	3/32	1/32	3/32	1/32
Thickness of inner tube	....	3/32	....	3/32	....	3/32
Thickness of cover	....	1/16	....	1/16	....	1/16

Note: All dimensions are in inches.

IV—WORKMANSHIP

Inner Tube—8. The inner tube may be made either by hand or machine. It shall be free from holes and other imperfections, and shall be so firmly joined to the cotton fabric that it cannot be separated without breaking or splitting the tube.

Wrapping— 9 (*a*) The canvas or woven fabric used as a wrapping for the hose shall be made of long fiber cotton, loosely woven, from 38 in. to 40 in. wide, and shall weigh not less than 20 oz. to 22 oz. per yard, respectively.

9 (*b*) The wrapping shall be frictioned on both sides and shall have, in additon, a distinct coating or layer of gum between each ply. It shall be applied on the bias with edges tapped at least ½ in.

V—MARKING

Serial Number—10. Each lot of hose of 200 or less shall bear the manufacturer's serial number commencing with "1" on the first of each year and continuing consecutively until the end of the year.

Label—11. Each hose shall have vulcanized on it a label of red or white rubber as shown in Fig. 3, located 6 in. from one end. Lettering and figures shall be not less than ¼ in. high, except name of the manufacturer, which shall be not less than ⅛ in. high. All letters and figures to stand in relief, not less than 1/32 in.

VI—INSPECTION

Inspection—12 (*a*) Inspection shall be made at destination, unless otherwise specified on order. The manufacturer, however, shall not rely upon the purchaser's inspection but shall provide sufficient inspection to insure against shipment of hose that do not conform to this specification.

12 (*b*) Where inspection is called for to be made at place of manufacture, the manufacturer shall afford the purchaser's inspector, free of cost, all reasonable facilities to satisfy him that hose are being furnished according to this specification.

Acceptance—13 (*a*) If the test hose conforms to Sections 2 to 6, inclusive, the entire lot from which it was taken will be examined and those complying with the specification will be accepted.

Rejection—13 (*b*) If the test hose fails to meet the requirements of Sections 2 to 6, inclusive, the entire lot from which it was taken will be rejected and the manufacturer notified.

Freight Charge on Rejected Hose—14. Rejected material will be returned to the manufacturer, who shall pay freight charges both ways.

Retests—15. Hose rejected in accordance with Sections 13 (*a*) and 13 (*b*) will be held for twelve working days from date of test report. In case of dissatisfaction with results of the tests, the manufacturer may make claims for retesting within that time.

Lighting of Electric Street Cars—The committee submitted as an appendix to the report an extended study of car lighting, showing the economy of modern metallic filament lamps, the use of various forms of reflectors, details of cost and typical layouts of lighting units. In general, the data are similar to those published in the ELECTRIC RAILWAY JOURNAL within the last year or two on the tests of the Bay State Street Railway, Cleveland Electric Railway and others.

Lightning Protection—In conclusion the committee reported on the replies received to its data sheet on lightning protection. The investigation revealed the fact that several of the larger companies have entered into exhaustive research work, notably the Denver Tramways and the Pittsburgh Railways. The committee recommended that in view of the importance of the subject it be continued.

Report of Committee on Standards Concerning Certain Recommendations of the Committee on Equipment, 1913-1914:

Recommendation of the committee on equipment: (*a*) As standard: Specification for solid wrought carbon steel wheels for electric railway service.

Action of the committee on standards: Adoption as a standard specification approved.

Recommendation of the committee on equipment: (*b*) As recommended specification: Specification for air brake hose.

Action of the committee on standards: Adoption as a recommended specification approved.

Recommendation of committee on equipment: (*c*) Wires and cables for car equipment: That further consideration of this subject be postponed.

Action of committee on standards: That the executive committee assign to the ensuing committee on equipment the general subject of "Car Wiring" with special reference to fire protection.

Recommendation of committee on equipment: (*d*) Revision of present standard specification for heat-treated carbon-steel axles, shafts and similar parts: That it be given more time to investigate.

Action of committee on standards: Recommendation approved.

Recommendation of committee on equipment: (*e*) Specification for gears and pinions: That it be given more time to investigate.

Action of committee on standards: Recommendation approved.

REPORT OF THE COMMITTEE ON FARES AND TRANSFERS

The committee on fares and transfers of the Transportation & Traffic Association presented yesterday conclusions on city conditions as follows: That the prepayment system of car operation is firmly established, and that fare boxes also have come to stay; that if the perfect fare box has not arrived the reason is probably that the users have not yet made up their minds as to what they want; that with a showing of 1 to 15 per cent in increased receipts there are several apparent advantages in the use of fare boxes; that few conductors have objected to the boxes on the ground of inaccuracy; that the practice of having tickets rung on a separate register does not appear to be a complete success and hence has led to the search for suitable metal tickets. On the last point the committee stated that there seemed to be no real danger of counterfeiting such tokens, but railway operators contemplating their use should remember that the federal government objects to the use of anything that resembles in color, design or inscription any United States or foreign coin. The committee did not express any opinion on transfer machines, but hoped that they would be discussed at the convention for further study because effective machines of this type would be very desirable.

The conclusions on interurban matters were as follows: That remittance by conductors should be on the closed system; that the verbal method of indicating to another conductor the right of a passenger to ride beyond a certain point is productive of abuses and should be replaced by an exchange or destination check, in form of a hat check printed with names or numbers of stations and numbered for record. The committee also stated that most of the companies which filled in the data sheets use some form of register for making a record of cash collections. It noted in conclusion that in several states the 2-cent-per-mile law is being applied to interurban passenger tariffs, and to avoid the troubles occasioned by the old method of computing fares by fare division points several of the larger interurban companies are now compiling new tariffs which split the nickel. This method, the committee said, will give the opportunity to place a redemption value on cash fare receipts without the loss of any percentage of the revenue by adding to the cash fares collected by conductors enough pennies to make the amount end in 0 or 5, and to make the receipt good for redemption of the extra penny or pennies at any agency.

REPORT OF THE COMMITTEE ON PASSENGER TRAFFIC

The report of the committee on passenger traffic of the Transportation & Traffic Association, read yesterday, was devoted largely to the trackless trolley and motorbus. Only the main points need be mentioned here, as the Electric Railway Journal has previously published so much on this subject, particularly the report made to the Board of Estimate and Apportionment, city of New York, by John A. McCollum (see issue of Nov. 22, 1913). After noting that the trackless trolley is used in but one or two places in this country, the committee considered the motorbus. Of the total bus companies reported but two out of fourteen are operated by electric railways as feeders for interurbans. Seven bus companies are reported as failures. The Indianapolis company failed despite a street railway reconstruction period and a 5-cent fare; in Pittsburgh, bus service through a fine residence section was given up with the advent of winter; in Detroit a municipal bus line at a 3-cent fare and a maximum ride of 6.5 miles was abandoned after a short trial, and a line at Hoboken, N. J., also found a 3-cent fare impossible despite heavy business. Interurban lines between Greenfield and Maxwell, Ind., and Morristown and Madison, N. J., also failed. The zone system is used except in New York and Washington, New York charging a straight fare of 10 cents and Washington 5 cents or six for a quarter. The latter company is operated at a loss. In all cases the buses are operated over paved streets. Bus companies have no paving charges, but in Massachusetts and New York their gross receipts are taxed and the former State also has a franchise tax. The situation in New York as to bus competition was discussed on the basis of Mr. McCollum's studies.

Eight private bus companies are contemplated, the largest being Los Angeles, Cal., with 105 vehicles, to go into service January, 1915. Five motorbus companies are trying to get franchises for a 10-cent service in Chicago. A similar rate of fare is contemplated by an applicant at Houston, Tex., while the Philadelphia Rapid Transit Company is seeking the right to operate motorbuses where it deems them desirable.

The committee concludes that while the possibilities of the motorbus are great, they will not be attained until the operating cost and rate of depreciation are decreased. At present it does not appear to be a serious competitor to the city railway except where roadway and traffic conditions are very favorable. To render them successful as feeders to interurbans, good roads, large population and reliable service are essential. The committee also discussed the development of new business; the distribution of traffic, especially peak loads; and improvement in public relations through the medium of the traffic manager and his department.

REPORT OF JOINT COMMITTEE ON CLAIMS ACCOUNTING

The joint committee on claims accounting of the Claims Association and the Accountants' Association submitted yesterday a classification of accidents with brief instructions for its use. The names of the fourteen accounts are as follows: Collisions with pedestrians; collisions at railroad crossings other than the company's; collisions between cars of the company; collisions with vehicles; derailments; defective equipment; boarding cars; injured or thrown while in cars (not in collision); alighting from cars; falling from cars (not purposely alighting); stealing rides; doors, gates and guardrails; ejectments, and miscellaneous. This primary classification is deemed to be sufficiently inclusive for all companies, and each company can insert subheads under the different accounts to suit its own convenience. Additional titles may seem necessary for subway or elevated railroads. These may be adopted as divisions of the miscellaneous group or even added separately. In the latter case they should be so defined that other members might readily understand that for comparison they should be included in the miscellaneous group.

REPORT OF THE COMMITTEE ON PUBLIC RELATIONS

The report of the committee on public relations, presented yesterday before the American Association, referred first to the appointment of a sub-committee to prepare a code of principles and to outline a comprehensive plan of educational publicity. This sub-committee consisted of James H. McGraw, chairman; C. Loomis Allen, Frank R. Ford, Guy E. Tripp and Col. T. S. Williams. Thomas N. McCarter, chairman of the general committee, was also an ex-officio member of the sub-committee. This sub-committee submitted for approval the following code of principles:

Code of Principles

1. The first obligation of public utilities engaged in transportation is service to the public.

The first essential of service is safety.

Quality of service must primarily depend upon the money received in fares. For this reason it is necessary that the rate of fare should be sufficient to permit the companies to meet the reasonable demands of patrons and to yield a fair return on a fair capitalization.

2. Regulated private ownership and operation of electric railways is more conducive to good service and the public welfare than government ownership and operation because the latter are incompatible with administrative initiative, economy and efficiency, and with the proper development of cities through the extension of transportation lines. The interests of the public are fully protected by the authority given to regulatory bodies.

3. In the interest of the public and good service local transportation should be a monopoly and should be subject to regulation and protection by the state rather than by local authorities.

4. Short-term franchises are detrimental to civic welfare and growth because they ultimately check the extension of facilities and discourage good service.

5. In order to render good service, electric railways must be allowed to earn a fair return on a fair capitalization, and the foundation for this result will be obtained, if the issuance and sale of securities representing such fair capitalization shall be legally authorized to such terms as will produce the requisite funds.

6. Securities which have been issued in accordance with the law as it has been interpreted in the past should be valid obligations on which an electric railway is entitled to a fair return.

7. The relation of adequate wages to efficient operation should always be recognized, but electric railways, being public servants regulated by public authorities, should be protected against excessive demands of labor and strikes.

8. The principle of ownership of securities of local companies by centralized holding companies is economically sound for the reason that the securities of the latter have protection against the varying business conditions of a single locality or company and because money for construction and improvements can thus be more readily obtained.

9. In the appraisal of an electric railway for the purpose of determining reasonable rates, all methods of valuation should have due consideration.

10. Full and frank publicity should be the policy of all transportation companies, to the end that proper information may be available to the investor and the public.

Publicity and Educational Plans

The sub-committee also recommended the establishment under the auspices of the American Electric Railway Association of a Bureau of Public Relations, this bureau to have a competent director with the necessary assisting employees. The work of the bureau to be under the general supervision and direction of the committee on public relations of the American Electric Railway Association, with the power in that committee to appoint, either from its own membership or outside, sub-advisory committees, who will co-operate in the work of the bureau.

The committee on public relations to appoint the director of the bureau and his employees and to fix their compensation; also, so far as practicable, to make up in advance the budget of the bureau's expenditures.

The work of the bureau to be along the lines suggested from time to time by the committee on public relations and to cover particularly the following:

I. The dissemination of information and literature on subjects of general importance to public service corporations, including particularly: (a) Relations with employees; (b) public relations; (c) regulatory laws and commissions; (d) publicity concerning facilities, service and accounts; (e) rate making; (f) depreciation and reserve accounts; (g) taxation; (h) franchises.

The above contemplates close association between the bureau and member companies of the association as to the furnishing and distribution of reports, information and statistics, and it is suggested that each member company be requested to designate a representative through whom correspondence with the bureau may be conducted.

II. Co-operation with similar committees of other public service associations.

III. Influencing the sources of public education, particularly by:

(a) Lectures on the Chautauqua circuits.

(b) Formation of a commitee of prominent technical educators to promote the formulation and teaching of correct principles and public service questions in technical and economic departments of American colleges through courses of lectures and otherwise.

(c) Formation of a similar committee in each of the great technical societies, such as the electrical engineers, mechanical engineers, civil engineers, chemists, hydraulic engineers, telephone engineers.

(d) Formation of a similar committee to work in connection with the various civic and economic societies.

(e) Discussions at institutions of learning and Y. M. C. A.'s on subjects pertinent to the relations between the public and service corporations.

IV. The publication in magazines and periodicals of signed popular articles on public service questions by prominent workers in the electric railway industry.

V. Newspaper advertising when desirable and financially possible.

In order to provide the necessary funds for carrying on this work it will be necessary to raise a sum of money, to be subscribed and paid in installments as called for by the committee. All monies to be expended under the direction and upon the authority of the committee.

In continuation the sub-committee said: "Obviously the ability to carry out the extensive program outlined above will depend upon the raising of sufficient money and the wise expenditure thereof. Your committee believes that much of the work outlined can be accomplished through the assistance of advisory committees and at comparatively little expense. Even if the funds available should not permit the carrying out of the full program, much good may be accomplished if only certain phases of the work are undertaken. Your committee has enumerated advertising as one field of work and believes in the effectiveness of this method of reaching the public but it is convinced after careful consideration that to carry on any comprehensive program of advertising would involve the employment of more money than can probably be raised and it, therefore, recommends the use of advertising only for specific purposes and on special occasions where conditions would seem to justify the expenditure."

In addenda to its report the committee published some abstracts from the address of President Black at the mid-year banquet of the association, held Jan. 29, 1914 (reported in the issue of this paper for Jan. 31, 1914), also an abstract from the report of the public policy committee of the National Electric Light Association, presented at Chicago, June, 1913.

THE ASPECTS OF WORKMEN'S COMPENSATION LAWS

Under this title H. A. Bullock, secretary New York Municipal Railway, took up the economic, social and political aspects of the subject in a paper delivered before the American Association yesterday. He showed that no attempt to deal with the problem without due regard to those three aspects will succeed. In approaching it, the underlying economic conditions must first be carefully studied, after which a spirit of co-operation with all interests involved must be fostered. In States already having compensation laws the railway companies should not "cry over spilt milk" but should have recourse to the courts in case any act is confiscatory. In the State of New York, where the railroads opposed a fair compensation law in 1910, a victory for the anti-compensation forces resulted in an amendment to the State constitution containing features placing it in the front rank of radical compensation acts. Mr. Bullock advocated an intelligent conduct of the battle for fair treatment for employers, if such be necessary, in the light of thorough understanding of the problem rather than passive submission to injurious legislation. He advised against political wire pulling, attacks upon the constitutionality of particular measures and the use of "inspired" newspaper articles. He emphasized these points, among others: 1. State insurance has many disadvantages to the railroads. 2. A wide choice of method of providing compensation should be allowed. 3. Employers should endeavor to guard themselves against laws which remove their common-law defenses, while employees are fully protected. 4. Employers should have concern over laws fixing unreasonable compensation periods. 5. An effort should be made to prevent compensation commissions and their deputies from becoming a source of disturbance between employer and employee.

COMMITTEE ON EXPRESS AND FREIGHT TRAFFIC

The report of the committee on express and freight traffic of the Transportation & Traffic Association, presented yesterday, included the replies received from fifty-one roads in answer to a data sheet sent out by the committee. Only one road out of the fifty-one reported that it was maintaining a pick-up and delivery service. All of the roads were using a per-diem charge for carload business, being about equally divided between the steam-road basis of 45 cents per day and the C. E. R. A. basis of 50 cents per day. Practically all of the roads were using territorial classifications with exception sheets, and a large majority used local association demurrage rules of some kind, only eleven roads reporting the non-use of any such rules. About the same result appeared in the case of storage rules. All of the lines reported the use of either the unit way-bill, the blanket way-bill or both.

In the matter of uniform class rates the committee was unable to recommend either a maximum or minimum, considering that the matter of rates would still have to be a matter for local consideration. A recommendation for continuances of this investigation was, however, made for the ensuing committee.

A general discussion of the matter of advertising for freight traffic was given in the report, as well as a digest of franchises for handling freight and express traffic by electric lines in several states. The appendices to the report included also a reproduction of the data sheet sent out by the committee and a statement regarding the best form of organization for a freight and express department.

ELECTRIC RAILWAY SECURITIES FROM THE COMPANIES' STANDPOINT

In introducing his address on electric railway securities from the companies' point of view, Calvert Townley, director of the Lackawanna & Wyoming Valley Railroad, Scranton, Pa., deplored the fact that electric railway officials are now assenting by silence to the perpetuation of a misleading impression when they in general admit the past failures of railway men without stating with proper emphasis that the public not only assented to railway acts without a serious protest but even joyously partook of the resulting benefits. Mr. Townley believes that no one needs to be ashamed of the electric railway industry, and that if railway officials agree with him that their partner and their predecessors' partner, the public, has profited by the development of the industry as much as or more than the investors and the industry itself, this fact should be widely proclaimed instead of being the subject of abject apologies.

In Mr. Townley's opinion, the points of view of a railway and its customers are so diametrically opposed that it could not maintain a successful business if they were regularly allowed to fix the rates. The ultimate analysis of regulation shows that it is only to prevent investors from making too much profit. The key of the future salvation of railways is the fact that they cannot be successfully controlled and developed by fiat and decree, but must be accorded the customary time-honored bargaining rights in order to be fundamentally and economically safe. Real publicity is needed, not a mere exhibition of daily doings to the public gaze, but the establishment in the public mind of fundamental railway economics.

In such a class Mr. Townley groups the following principles: Railways must grow with the communities they serve, and over a period of years new capital needed for growth will always greatly exceed the additional receipts obtained from increased service. In other words, additions and extensions of existing roads cannot be financed out of earnings. Yet security selling is competitive, and the needed funds will not come from private sources unless the chances of a satisfactory return appeal to private investors. Moreover, this return cannot be permanently fixed, for commercial and financial conditions change constantly. In short, Mr. Townley concludes, unless the exercise of public control be reasonable and such as to insure safety to capital and stability of earnings while allowing wide latitude for satisfactory future returns, the resulting possible diversion of capital from electric railway securities will disastrously retard progress in the communities served.

INVESTMENT BANKERS AND PUBLIC SERVICE ACCOUNTANTS

The address on investment bankers and public service accountants by H. S. Swift, treasurer West Penn Traction Company, Pittsburgh, Pa., before the American Association yesterday dealt mostly with the gradually increasing influence of bankers in the financial affairs of public corporations, from their first small interest to their present representation in directorates and even direct control of management and operation. Mr. Swift outlines the various conditions that are usually studied by investment bankers in considering the underwriting of public utility securities. He states that bankers in analyzing reports were formerly guided by general rules regarding gross earnings per mile of road, maintenance per mile of track, etc., but that experience taught them the inelasticity of such rules and led them to follow the electric railway accountants in considering the car-mile as a unit of comparison.

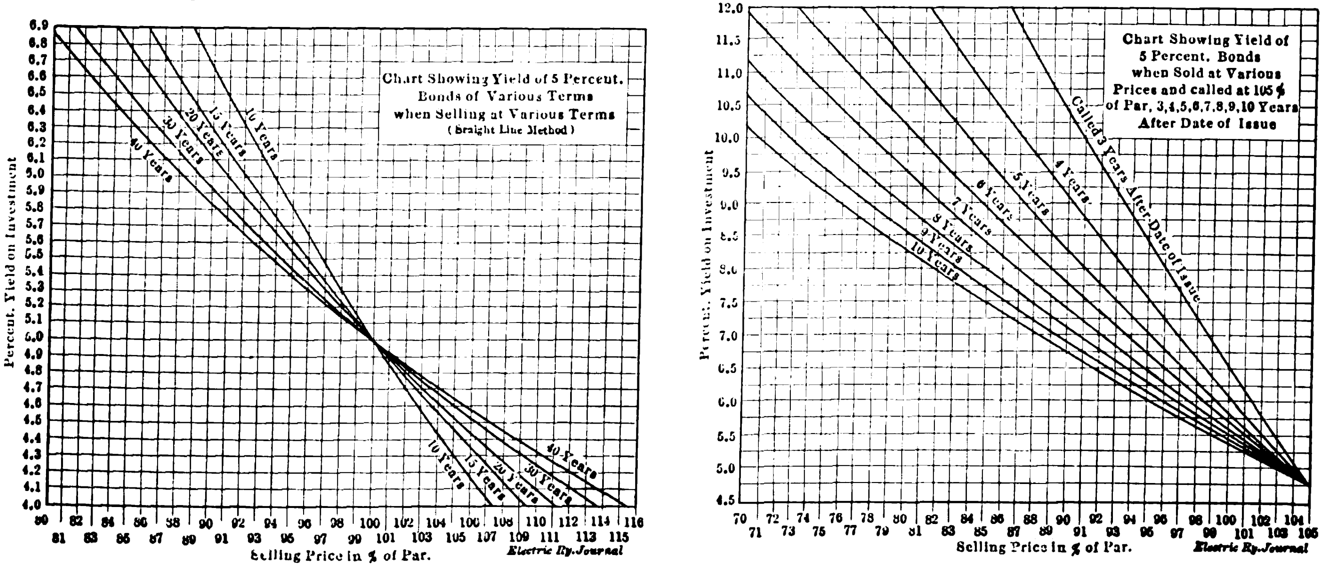
According to Mr. Swift, the growth of the statistical department of investment banking houses has been rapid, not only along the line of collecting public service commission as well as public utility reports, but also in connection with the analysis of operating reports for securing personal information and for answering inquiries of prospective purchasers. The information that bankers desire concerning public utilities serves two distinct purposes, first, to guide them in their decisions concerning the underwriting and purchasing of securities, for which purpose only pertinent facts are desired, and second, to provide a general story about the property that can be used as a sales talk to investors. No attempt seems to have been made by investment bankers to employ their statistical departments in making actual audits, such work being delegated to certified public accountants and consulting engineers.

Mr. Swift believes that investment bankers would like to see more uniformity in the distribution of expenditures between maintenance and construction and the ascertainment of some fairly accurate amount per car-mile or per mile of track and per car per annum that would represent a fair expenditure for maintenance, renewals and depreciation. They would also be interested in a completely detailed statement of construction expenditures. Mr. Swift notes, however, that although investment bankers can analyze public utility reports, they do not seem to have made efforts to unite with public utility accounting officers for making suggestions and discussing improved methods.

ACCOUNTING TREATMENT OF BOND DISCOUNT

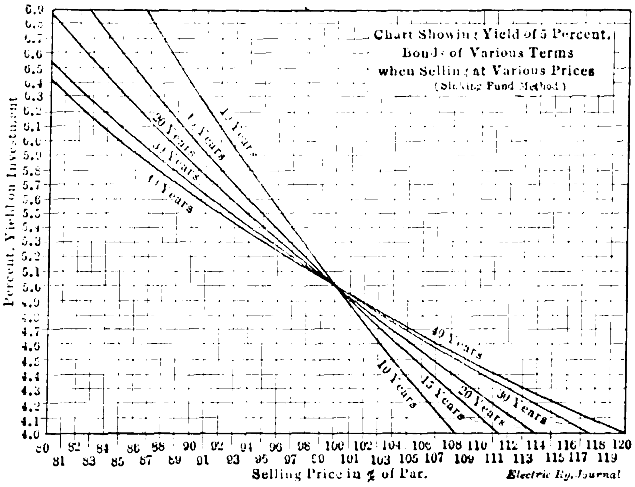
In the address delivered yesterday by James F. Fogarty, secretary The Milwaukee Electric Railway & Light Company, Milwaukee, Wis., on the subject of the accounting treatment of bond discount, the history of bond discount from 1897 to date was first briefly reviewed. Mr. Fogarty pointed out that discount was formerly regarded as the "initial cost" of borrowed money—i. e., the commission paid for its use over and above the annual cost represented by the nominal or coupon rate of interest. He also indicated the reasoning from which it has more recently been concluded that discount and nominal interest are closely related and together form the cost of borrowed money.

According to Mr. Fogarty, while current classifications of accounts do not prescribe uniform treatment of bond discount, the prevailing practice requires that it be regarded as a deferred cost which is properly chargeable to income and which should be amortized over the term of the security. To the extent that discount represents a part of interest during construction, it is recognized under current accounting practice as a proper charge against capital account. Bond discount is measured in part by the rate of return required for the investment of capital under the particular conditions surrounding the loan. It usually includes the cost of brokerage, or compensation of the investment banker incidental to marketing the security. From the corporation's point of view it is not possible to separate discount into its element of interest and brokerage; hence both costs are in practice treated as a part of the interest charge.



ACCOUNTING TREATMENT OF BOND DISCOUNT—CHART SHOWING YIELD OF 5 PER CENT BONDS

In cases involving reasonable rates and in the determination of income for purposes of taxation, bond discount has only an indirect effect, according to Mr. Fogarty. It is generally considered as a part of the rate of return rather than as an element of the cost of property. In conclusion Mr. Fogarty stated that the weight of authority prescribes that bond discount be amortized from income in order to extinguish it as a capital asset. It may be written off by annual accruals through either the sinking fund or the straight line method of amortization, but, while both methods lead to the same results, the straight line method seems to be generally preferred because of its greater simplicity.



ACCOUNTING TREATMENT OF BOND DISCOUNT—CHART SHOWING YIELD OF 5 PER CENT BONDS

In connection with his address Mr. Fogarty presented three interesting diagrams, reproduced herewith, to show the effect of bond discount in increasing nominal interest rates and the effect of the sale of bonds at a discount and their redemption at a premium. For instance, by reference to the diagrams it will be seen that the sale at 88 of a thirty-year 5 per cent bond results in an actual interest cost of 5.854 per cent calculated by the sinking fund method, and 6.136 per cent calculated by the straight-line method. Similar computations can be made for the various terms of life, rates of interest and sales prices of bond issues.

REPORT OF THE COMMITTEE ON INSURANCE AND FIRE PROTECTION

The report of this committee of the American Association, presented yesterday, stated that it had received reports from 274 companies for the year 1913; 122 companies made no report. These reports show:

Amount of insurance carried	$317,846,276	
Amount of premiums paid	1,779,671	
Amount of fire losses	599,498	
Amount recovered	533,453	
Ratio of recoveries to losses	88.9	per cent.
Premiums per $100 of insurance	56	cents
Losses per $100 of insurance	18.7	cents
Recoveries per $100 of insurance	16.7	cents
Ratio of losses to premiums	33.5	per cent.
Ratio of recoveries to premiums	29.8	per cent.
Number of fires	143	

More members reported this year than in any previous year. The losses of 1913 were higher than those reported in any previous year except one; but the rate of insurance was the lowest in the history of electric railway insurance as disclosed by the committee's reports.

Of the $1,779,671 paid for insurance, $533,453, or about 29 per cent, was returned to the insured for losses, leaving about $1,250,000 for commissions to agents and others, for other expenses of conducting the insurance business and for dividends. Some of the members included in their insurance and premiums boiler insurance, flywheel insurance, tornado insurance, burglary insurance, automobile insurance, and possibly other insurance, but these companies were only three in number, so far as the committee knows, and the elimination of the cost of these other forms of insurance would not materially alter the average cost as shown by the tables.

Fourteen companies reported that they carried no insurance, and three companies reported that they carried their own insurance. Four companies reported the amounts of insurance carried by them, but did not feel at liberty to report the premiums paid. One company reported the amount of premium paid, but failed to state the amount of insurance carried. In these cases the committee has assumed that the rate was 50 cents per $100.

Fifty-nine companies reported fires. Of the 143 fires of the year, thirty-six were reported by one company. The committee has assumed that companies that reported no fires had none.

Several fires from overheated resistance, diverters or grids were reported, and others from the same cause occurred early in the year 1914. Fires from this cause were so frequent that the committee endeavored to find a remedy, and with that purpose in view corresponded with electric railway engineers, car builders, insurance engineers and others. No better remedy was suggested than that contained in the rules and regulations of the National Electric Code, formulated and published by the National Board of Underwriters, and a rule requiring conductors to tie down their trolleys when leaving cars in yards and motormen to remove their controller handles.

Sixty-one members reported that they had equipped buildings to the number of 266 with automatic sprinklers. The amount invested in automatic sprinkler protection, as indicated by these reports, was $1,650,000, but several companies that reported sprinklered buildings failed to report the cost of their sprinkler equipment. This investment shows that railway companies are protecting their property, and this is probably the principal reason for the reduction in the average rate of insurance.

Attention is called to a report presented to the American Electric Railway Engineering Association in 1913 by its committee on buildings and structures, containing rules for the protection of buildings and for fire drills. These rules have since received the approval of the National Fire Protection Association.

Insurance companies have continued to give particular attention to the insurance of railway properties, and have reduced their rates to companies that have been able to show that they were entitled to lower rates.

In the opinion of the committee, a lower average rate for the entire industry than the 56 cents shown in this report ought not to be expected unless the hazard of fire is still further lessened. In the long run, it is to the interest of the electric railway business that rates on properties not efficiently protected and guarded be high, in order to induce their owners to put them in safer condition. Fire prevention is much more important than the collection of fire losses. Electric railway properties can be placed among the most desirable risks, from the viewpoint of fire insurance companies, by the installation of approved devices for the prevention or quick extinguishment of fires, and by the exercise of only ordinary care on the part of officers and employees in the upkeep and cleanliness of buildings, yards and rolling stock.

TABLE SHOWING CAUSES OF FIRES, COST AND LOSS DURING THE LAST YEAR

Causes of Fires	Number of Fires	Loss
Adjacent property	6	$426
Boiler blowout	1	
Broken span wires	3	
Car heater	1	2
Car wiring	1	1,801
Cigar stubs, cigarettes, matches	10	1,442
Clothing hanging near stove	1	
Collision	1	19,386
Collision, train and automobile	1	1,875
Defective car heater	1	70
Defective car wiring	2	201
Defective insulation	1	1,125
Defective stove in car	1	94,717
Dropping of trolley wire	1	1,750
Electrical	26	7,395
Electric heaters	2	2,367
Fireworks	1	2,000
Ground wire	1	25
Hot ashes	1	120
Incendiary	3	245
Lightning	8	266,081
Match thrown in window pocket	1	4,529
Overheated journal	1	
Overheated resistance	4	7,612
Overheated stove	6	5,831
Short-circuit	2	1,278
Short-circuit in transformer	1	17,000
Short-circuit in high-tension wire	1	
Smoking	1	
Spark from generator	1	730
Spontaneous combustion	2	94
Tramps	2	538
Trolley down on car on bridge	1	150
Trolley wire broke stove pipe in car	2	7,648
Unknown or not reported	45	153,060
Total	143	$599,498

TABLE SHOWING CLASSES OF BUILDINGS INJURED BY FIRE DURING THE LAST YEAR

Property Damaged	Number of Fires	Loss
Carhouses and cars	53	$451,567
Stations and depots	6	3,342
Power stations	3	859
Substations	3	17,407
Store houses	3	30,144
Shops	2	4,015
Oil houses	2	1,676
Park buildings	5	14,946
Other buildings	19	19,163
Electric victor machine	1	900
Unknown or not stated	46	55,479
Total	143	$599,498

The committee submitted several tables with its report. One showing the different causes of fires, and another showing the different classes of buildings injured by fire during the past year, are reproduced.

BUREAU OF INSURANCE

The report concluded with a report to the committee from Henry N. Staats, insurance expert. Mr. Staats said, first, that he thoroughly indorsed the rules laid down for the prevention of fire by the American Electric Railway Engineering Association in its Proceedings of 1911, under the head of "Fire Protection of Carhouses." He also reported that the rules drafted by the committee on buildings and structures of the American Electric Railway Engineering Association to cover the instruction to employees bearing upon fire protection and maintenance had been approved by the committee on railway, light and power properties of the

National Fire Protection Association. This committee consists of C. H. Patton, chairman, Cleveland; R. C. Bird, H. J. Davies, J. C. Forsyth, M. F. Jones, J. V. Parker, A. M. Schoen, Martin Schreiber, H. N. Staats, R. Swetland, L. Wiederhold, Jr., and A. G. Wilbor.

Mr. Staats also reported that the Central Traction & Lighting Bureau (composed of old-line insurance companies) had, after several years of controversy and delay, issued its schedule for rating electric railway properties. A strict application of this schedule would result in an increase in the present cost of insurance. In conclusion, he said that if electric railway managers would follow the rules adopted by the American Electric Railway Engineering Association for standard buildings and structures, for protection and inspection of their properties and for car heating and car wiring, they should obtain a rate of 10 per cent or less on each $100 of insurance carried; or they could safely carry their own insurance, and make money in so doing.

REPORT OF THE COMMITTEE ON BUILDINGS AND STRUCTURES

The report of the Engineering Association committee on buildings and structures, presented yesterday, stated that the executive committee had assigned the following subjects for consideration of this committee: "Fire Protection Rules" (to be given joint consideration with the National Fire Protection Association), "General Specifications and Form of Contract," and "Power House Construction." A sub-committee was appointed to obtain the approval of the fire protection rules, contained in Section 1 of Appendix B, page 406 of the 1913 Proceedings, by the committee on electric railway and power properties of the National Fire Protection Association. This approval was obtained, and the rules were set forth in the report. It was also recommended that these fire protection rules be again referred to the committee on standards for its recommendation.

The sub-committee on general specifications and form of contract submitted a form of contract and general conditions of specifications, that had been approved by the committee as a whole, and it was recommended that these forms be approved for adoption as standard.

The sub-committee on power house construction called particular attention to its report on this subject, which was found to be exceptionally broad, and one which should make an intensely interesting and valuable study for the association. To secure definite results on this subject the committee made certain assumptions which included the size of the station, the character of the load, the station site, the locations of the coal and ash-handling equipment, the arrangement of water conduits, main building and shop, and distribution of cost. With these assumptions a general synopsis of the whole plant was made and submitted for consideration.

REPORT OF COMMITTEE TO CONSIDER RELATIONS WITH SECTIONAL ASSOCIATIONS

The committee of the American Association on relations with sectional associations reported yesterday that it did not recommend any changes in the amendment to the constitution adopted last year providing that all members of such associations must be members of the American Association. The committee believed that closer relations should exist between the American Association and the smaller associations scattered throughout the country. There is a tendency toward co-operation, as was indicated by the action of the Central Electric Railway Association's arrangement with the Engineering Association for co-operation in the matter of standards. . The presidents of the section associations were invited to attend the midwinter convention of the American Association.

REPORT OF THE COMMITTEE TO DEVELOP UNIFORM DEFINITIONS

The Transportation & Traffic Association committee appointed to develop uniform definitions reported yesterday that at the 1913 convention the committee had presented thirty-nine definitions of terms. Due to lack of time, these definitions received no consideration, the report being accepted but no action being taken thereon. Under such circumstances, uniformity in terminology will not be assured. The committee, therefore, presented yesterday a report which includes the definitions presented in 1913, and, in addition, called attention to other definitions heretofore adopted by the association, principally in the reports of the committee on construction of schedules and time-tables. As some of the definitions presented last year were inconsistent with definitions previously approved, where such non-conformity appeared both definitions were shown and the convention was asked to take such action as will definitely give one of the definitions the approval of the association. The committee feels that the association should not, without due discussion, place upon its records recommendations of such importance as the standardization of terms.

REPORT OF COMMITTEE ON AWARD OF MEDALS FOR BEST PAPER READ BEFORE A COMPANY SECTION

The American Association committee on the award of a medal for the most meritorious paper delivered before a company section during the year reported yesterday that nine excellent papers had been examined. (For list see ELECTRIC RAILWAY JOURNAL, October 10, 1914, page 774). The committee unanimously concluded that the award should be made to H. G. Abendroth, of the Milwaukee Electric Railway & Light Company section. [Mr. Abendroth's paper was entitled "Overhead Charges in Valuations." An extended abstract of this paper was published in the issue of the ELECTRIC RAILWAY JOURNAL for June 27, 1914, page 1434.—EDS.]

REPORT OF THE COMMITTEE ON ELECTROLYSIS

The American Association committee on electrolysis reported yesterday to the effect that the association has appointed two of the members of this committee along with one representative of the American Electric Railway Engineering Association as delegates to the national committee to consider electrolysis. As the engineering and technical questions involved are being considered by the electrolysis committee of the American Electric Railway Engineering Association, the committee concludes that it can best serve the interests of the association and avoid duplication of work by keeping in close touch with the work of the above mentioned delegates and with the engineering association's committee, rather than by itself giving the subject independent and comprehensive study. The committee reported satisfactory progress along these lines and suggested the continuation of the committee for another year or until such time as the association decides that its duties shall terminate.

An Englishman recently returned from Brussels, tells the following story: "About 150 German officers are quartered at the house of the manager of the Brussels tramyards at Uccle. One night, after dinner, a major sent for him and said that he had not given them the best wine that he had in his cellars. The host protested that he had, but the major said, 'You have not. I know where there is some better champagne, and if you will hand over your keys I will fetch it myself.' The manager looked closely at the officer and said, 'I seem to know you.' 'Yes,' replied the major, 'I was your chauffeur once for six months.'"—*Electric Railway & Tramway Journal, London.*

THE ASPECTS OF WORKMEN'S COMPENSATION LAWS*

By Edwin Gruhl, Assistant to President North American Company

While in late years there have been many additions to the list of workmen's compensation acts, many of a comprehensive character, it is a mistake to assume that a complete and satisfactory program has been developed anywhere. There seem to be differences in the theory underlying the various laws as well as in their prescribed methods of application. Mr. Bullock has pointed out in a comprehensive way the economic, social and political aspects of the problem which must be considered before a satisfactory solution can be reached.

Perhaps the most important administrative question is how the company can best be insured against compensation losses. Both the employee and the company are interested in the greatest protection at least cost. Four methods are possible in providing such insurance: (1) state insurance, administered and controlled by public officials, such as occurs in Washington and Ohio; (2) insurance by stock companies; (3) insurance by a mutual company comprising employers engaged in a similar industry, and (4) self-insurance. It is still too early to say which is the most economical, but there are several reasons why the administration by a mutual association conversant with the problems of one industry or, if the company is of sufficient size, self-insurance, is the most satisfactory.

1. The problem of assessing the cost of insurance over different types of employment is more complicated than we are frequently led to believe. Many years will have to elapse before sufficient experience data are available to place equitably upon each industry its proportionate cost of the risk. Each machine carries with it its peculiar hazard, and each operation its own danger. The classes of employees in the traction industry are unusually diverse, ranging in hazard from bookkeeper to lineman and comprising every variety of indoor and outdoor employment. It is impossible at this time to devise a single premium rate or set of rates which will conform to the average risk of any particular company and where such uncertainty exists it is to be expected that any stock company or state department will exaggerate the risk and overstate the rate. During the necessarily slow period of developing standards and accurately measuring risks it is of interest at least to follow carefully individual loss ratios if not to provide and administer the actual insurance for workmen's compensation—to experiment rather than be experimented with. Any possible savings can well be invested in other forms of employees' welfare.

2. We may well question the inherent economy of compulsory state insurance. There are too many obviously unsolved problems of economy and efficiency in the usual state departments to expect that insurance funds will be safely invested at the maximum return or that overhead charges will be kept at an irreducible minimum. With varied industries claiming its attention a high degree of organization will be necessary if the state bureau is properly to fulfil its designed function.

3. Workmen's compensation is only one of the phases of what has frequently been termed social insurance. Judging from current discussions and the character of proposed legislative enactments in many states it will not be long before we will be asked to consider that the compensation for accidents while on duty be supplemented by schemes which provide insurance for accidents off duty, for sickness, for unemployment, for old age pensions, etc. Many traction companies, impressed with the necessity for a broad welfare policy, are already providing some of these benefits through mutual societies. The success of such plans has depended largely upon the realization by the employee of the mutual interest he has in the well-being of his company and of his co-employees and in seeing that such welfare plans are properly administered and the funds of the association not paid out in cases of malingering and fraud. Such a mutual interest is impossible under state insurance.

4. Only where the traction company carries its own insurance or carries its insurance in a sufficiently confined mutual company, so that its interests are not merged with a large number of diverse industries, can there be any automatic reduction in cost because of the activities of the "safety first" movement. Fire insurance companies through long experience endeavor to make equitable reductions in rates because of type of construction of buildings, installation of sprinkler systems and the elimination of fire hazards. It does not call for much play on the imagination to picture the difficulties which would be encountered by any insurance expert in trying to ascertain the proper reduction to be made in the rate because of the effect of the company's "safety first" movement.

CARRANZA SWOOPS DOWN ON MEXICO CITY TRAMWAYS

The New York *Evening Post* for Wednesday, Oct. 14, contains the following startling story from Mexico City of the seizure on Oct. 12 of the local public utilities by the present arbiters of still-harried Mexico:

"The seizure of the Mexico Tramways Company lines by the Carranza government to-day was made at the point of the bayonet.

"The Mexican Tramways Company, Ltd., is a Canadian corporation capitalized at $1,000,000. Its home office is in Toronto, Ont. Shortly before noon, soldiers surrounded the main building occupied by the office and plant, while a delegation of officials entered the premises and served notice upon General Graves that all the books, rolling stock and other property of the company, with the exception of the cash in the vaults, must be delivered to the chief of police. The order was given in the name of the supreme chief, and was signed by the governor of the federal district.

"The government explained that the measure was a provisional one taken in the interests of public welfare, and due to the stoppage of the street-car traffic of the city on noon of last Thursday, when the motormen, conductors, inspectors and shop men struck because their demands for a 100 per cent increase in wages, an eight-hour day, and recognition of the union were not granted by the company in the four hours' time limit specified by the strikers' committee.

"The principal owners of the property are English, French and Belgian, with some American stockholders. All foreign employees were kept in the building at the behest of the troops. The management has made a vigorous protest to the Brazilian, British, French and Belgian Legations. A formal protest was registered also with Carranza.

"Carranza later designated Tomas Ramos as acting general manager of the system. The lines of the company form a network over the entire federal district, extending for nearly 250 miles, and carrying millions of passengers monthly.

"Due to a depreciation in the Mexican peso, the management informed the government to-day of its inability to grant the demands of the men for shorter hours and double wages, saying that passengers now were being transported at less than 1½ cents gold. Immediately after this reply of the company was made, soldiers took possession of the property.

"The act has caused a sensation here, as the tramway company and the allied Mexican Light & Power Company, Ltd., supply all the light, power, heat and transportation within a radius of 30 miles of the capital. The joint investment of the allied companies represents nearly $100,000,000."

---

*Abstract of written discussion of the paper by Mr. Bullock on this subject presented at the meeting of the American Electric Railway Association, Atlantic City, N. J., Oct. 14, 1914.

REPORT OF THE WAYS AND MEANS COMMITTEE

The report of the ways and means committee of the American Electric Railway Association was presented yesterday. This committee was appointed at the mid-year meeting of the association and was instructed to devise methods for the increase of the association's receipts and to effect, if possible, economies in the association's expenditures.

The committee said that under its instructions three matters of extraordinary importance connected with the finances of the association presented themselves during the past year for its consideration. The first of these was the question of the support of *Aera*, and acting with the *Aera* advisory committee and under the authority of the executive committee the printiing of advertisements in this magazine was resolved upon, to take effect with the January issue. An advertising solicitor was appointed and efforts were made in various ways to interest manufacturers in *Aera* as an advertising medium. Business conditions have been adverse and the difficulties that have presented themselves were many. In view of these circumstances, however, the committee believes that a fairly satisfactory showing has been made and is confident that a decided increase in the advertising carried will be evident during the coming year. In the meantime, it is the purpose of the committee to effect such economies as will, it is hoped, bring the expenditures for *Aera* into a closer ratio to its receipts.

The matter of financing the fare research bureau also received attention by the committee. According to its report, this important function of the association was put in operation on May 1 with the appointment of a director, at which time an appropriation of $2,500, made by the association, for the first year's work, was available. In addition to this sum of money, the committee proposed to enlist the aid of fifty member companies and to secure from these companies subscriptions to a fund which would provide for the maintenance of the bureau for a period of three years. In view of business conditions, however, it was later resolved to defer the call for these contributions. In the meantime the members of the committee on the cost of passenger transportation service have provided a sum of money which will care for the finances of the bureau until such time as it seems advisable to issue the call to the larger list of companies. The thanks of this association, the committee says, are due to the members of the committee on the cost of passenger transportation service for their great generosity which has enabled the bureau to inaugurate the very valuable work which it is designed to carry on.

The question of the dues of member companies was given to the ways and means committee for its consideration, and at the January meeting a report was presented to the executive committee covering a scale of dues which, if put into effect, would provide some $16,000 additional revenue each year. In this connection the committee called attention to a letter sent out with the proposed amendment to the constitution and which explains in detail the reason and necessity for this action of the association. Continuing the report says:

"The work which the association is doing is constantly increasing. No organization in the country of similar magnitude, doing so large a work, is operated so economically as is this association. Nor is the scale of dues in any similar organization so low. The additional revenue is a necessity, and the increases proposed are, in no case, excessive. Work for electric railways of a value scarcely to be estimated is being carried on by the association, and in no other way can the results which we are achieving be secured for member companies as cheaply and as efficiently. Your committee, therefore, urges upon you the duty of supporting the proposed constitutional amendment, believing that the benefits to be derived warrant in full measure such additional expense as the individual companies may be called upon for. The inauguration of the new scale will increase the receipts from company and individual membership from $52,000 a year to $68,000 a year. This increase is a necessity unless the activities of the association, which are of so much value to the electric railways of this country, shall be materially curtailed, and your committee believes that the proposed constitutional amendment is worthy of and should receive unanimous approval at your hands."

REPORT OF ANTHONY N. BRADY MEDAL COMMITTEE

The report of the American Association committee appointed to formulate conditions of competition for the Anthony N. Brady gold medal was presented yesterday afternoon. It referred to the fact that in February the American Electric Railway Association was notified by the American Museum of Safety that it had been authorized to make an award annually of a gold medal, with a silver and a bronze replica, in memory of Anthony N. Brady, to that American electric railway company which for the year of award should have done most to conserve the safety and health of the public and of its employees. The Museum of Safety requested the American Electric Railway Association to appoint a committee to formulate the conditions of competition for this medal. The president of the association appointed as the members of such committee Arthur W. Brady, chairman; Frank Hedley and C. S. Sargeant. This committee formulated the conditions for the competition, which were submitted to the president of the association and approved by him. [A copy of these conditions was printed in the ELECTRIC RAILWAY JOURNAL for May 9, 1914.] They follow closely the conditions formulated for the award of the E. H. Harriman gold medal to the American steam railways making the best safety record. The report then goes on to say that, in the form adopted, these conditions were sent to the electric railways of the country in June last. Much interest has been manifested, and several companies have entered the competition for the year ending June 30, 1914. The committee appointed by the president to make the award consists of the following: Bion J. Arnold, chairman; James H. McGraw, Will J. French, Prof. George F. Swain and Frank J. Sprague. The committee suggests that the association recognize, by proper resolutions, the generosity and far-sighted public spirit manifested by the family of the late Anthony N. Brady in offering this medal.

ILLUMINATING BY SEARCHLIGHTS AT THE PANAMA-PACIFIC EXPOSITION

Four hundred giant searchlights will be used next year to flood the palaces and gardens of the Panama-Pacific International Exposition with vari-colored light. Two hundred of these have already been received. Half of the shipment consists of 18-in. instruments and half of 13-in. reflectors. These are the smallest searchlights which will be used and are to be installed on the roofs of all the main exhibit palaces, above the arches over the entrance gates, and on the six main towers of the courts, including the Tower of Jewels. The great reflector on this tower will be 432 ft. above the ground.

The other searchlights, to arrive within a few weeks, will include 100 30-in. lights, 100 18-in. and many colored scintillators, consisting of a battery of monster lights and projectors 3 ft. and 4 ft. in diameter, to be set up on the breakwater, just east of the California Building. At night this enormous searchlight will play symphonies of color on the clouds, and will be met by the powerful beams from another enormous searchlight which will be set up on the crown of Mount Tamalipas, 15 miles away across the bay.

Traditional custom and desire makes plain commercial rivalry and friendliness our means of conquest in South America.—*Electrical World*.

THE TRANSPORTATION DEPARTMENT AND THE CHANCE IT OFFERS*

By N. W. Bolen, General Superintendent Public Service Railway

A transportation head of an electric railway system is comparatively modern, so far as the title is concerned, being practically coincident with the introduction of electrically propelled cars. The carhouse foreman was the czar of the early horse car railway, and his duties were many. He selected the horses and mated them, saw to their shoeing, purchased the corn and oats and hay for their feed; employed the drivers and conductors and enforced discipline among the employees with a heavy hand. By rule-of-thumb methods, he developed schedules and determined headways and performed many functions that now are considered of sufficient importance to justify the maintenance of special departments.

With the advent of the electric car came changed conditions, the personnel of the men changed, and with the mustering out of the faithful mule and horse went many of the faithful men who had manned the cars in former days and in their places there arose a different type of employee. These changed conditions have been responsible for the evolution of the transportation man, and in any discussion of the opportunities offered him, his task is a primary consideration. In general he is charged with the responsibility of safely, speedily and comfortably transporting a major portion of the population adjacent to his lines, to and from their work. He must see that sufficient and proper equipment is provided; that trained and disciplined crews man the cars; that schedules are constructed to meet the wants of the passengers; provide workable hours for the trainmen and still be economical in operation. Many of his duties interlock with the work of other departments, and each department is as mutually dependent on the other.

The "Triple Entente"

The transportation man is subject to the "triple entente," namely: the public, the company and the employee. Heads of other departments have to work out the problems that involve the last two factors, but the transportation man has not only to meet the just and unjust criticism of the public concerning the operation of his department, but also act as mediator for other departments. The irate passenger who has missed his train due to a blockade resulting from a car splitting a defective switch or from a trolley wire down, is not prone to calmly withhold his wrath until he can, figuratively if not literally, lay hands on the head of the offending department. The transportation man, at this juncture, must prove himself a diplomat, if he is to smooth out the trouble and send the patron on his way with the proper feeling towards the company.

Amicable relations with the public are necessary, but of equal importance is the maintenance of proper relations with heads of other departments and the employees under his direction. In most cases it will be found that the man possessed of the qualities which make of him a successful leader among men, has but little trouble maintaining pleasant relations with his superiors and fellow officials. To obtain results and preserve discipline is a task that calls not only for energy and efficiency, but also for sympathy, and a spirit of personal interest in the employees under him.

Dean Schneider of the University of Cincinnati treats happily of what qualifications are necessary for success in his paper on "Selecting Young Men for Particular Jobs" under "Major Characteristics." Out of this paper quite an imposing list of qualifications might be developed for the ideal transportation man, but as really essential, the following ones stand out strongly: Good health, directive ability, personal magnetism, mental poise and willingness to assume responsibility.

To the young man possessing in a fair degree the qualifications named, the transportation department offers a field which will give him full opportunity. A majority of the transportation heads to-day are men who, like Topsy, "just growed up" in the business. These men have had but few sign posts to guide them, and the degree of success attained has resulted principally from the applications of such methods of operation found practical in the days previous to the advent of the electric railway. The more complex operating conditions to-day require greater development in operating practice than formerly, but the basic principles remain unchanged. This is an age of specializing, and the eyes of the executive and the manager are scanning the work of the young men in the service, looking for material from which heads of departments may be developed.

The unsettled question of the college-bred man versus the practical man with its pros and cons is left for others to debate. It is sufficient to say that the directing head of an army of transportation employees must, above all things, be a man in the full sense of the word for, after all, the dominant factor of his success will be his ability to handle men. Technical training is a great help to the transportation man in dealing with the mechanical department, the power and distribution department and the maintenance of way department, and the man who has such training is doubly blest. This, however, will in no way take the place of such qualities as being a good disciplinarian or a successful promoter of team work.

The technical courses of our universities provide much that the graduate may directly apply when he enters the engineering branch of electric railway work, but there yet remains the opportunity to provide a broad and comprehensive course in transportation training. Such a course would greatly aid the student of transportation when taking up his duties as a subordinate in actual service, but no amount of study will offset the necessity of obtaining first-hand knowledge of operating details. Through their actual performance and only by contact with various phases of the work can he obtain the training that will fit him for the responsibilities of the job higher up.

With the constantly increasing demand for economies in railway operation, the transportation end of the game has become a complex proposition. The public demands more for a single fare than it did formerly, the ride is longer, the cars are bigger, wages are higher and hours shorter, but the nickel is no larger. All of these call for higher efficiency in the transportation department as well as in other branches of the service. To the man who likes a varied existence, who is willing to work irregular hours and bear the responsibility of a public duty, the job will prove an attractive one, not from its financial rewards, but from love of the work, which is inherent to the born railroad man. The constant expansion of electric railway lines will require more men to fill these positions of responsibility, and to-day is the time for the young man to prepare himself. His course is well defined, and time will tell to what extent he has profited by his superior advantage over the pioneers of the craft who blazed the trail and derived their entire training in the hard school of experience.

---

*Abstract of paper presented at meeting of the Transportation & Traffic Association, Atlantic City, N. J., Oct. 14, 1914.

NEW YORK SUBWAY TRACK EQUIPMENT

The distinctive features of track equipment of the New York Subway are to be made the subject of a paper to be presented at the next meeting of the New York Railroad Club to be held on Friday of this week at 29 West Thirty-ninth Street, New York, the speaker to be O. O. Dixon, assistant engineer Interborough Rapid Transit Company, and an interesting evening is expected.

ELECTRIC RAILWAYS IN CHINA

At the present time only four cities in China have electric street railways; and of the four, three cities are only nominally in China. The Hongkong street railway is a British enterprise operating in a British colony; likewise, the Shanghai street railways are the property of British and French companies, and operate only in their respective national concessions, which are practically foreign territory. Similarly, the electric railway in Dairen (Dalny), South Manchuria, is a Japanese enterprise, built and conducted in a leased territory which, during the period of the lease, is to all intents and purposes a Japanese colony. In none of these three cities was it necessary for the British, French or Japanese companies to secure permission from the Chinese authorities to build and operate their respective street railways and lighting plants.

Of Chinese cities proper, Nanking has a light steam railway, 7½ miles in length, which provides facilities for only a small part of the city. The service is very infrequent, as there are only two locomotives on the line. The city of Mukden, Manchuria, has about 5 miles of track, on which very small horse cars are operated at irregular intervals; but the rails were copper bonded when laid, and it is proposed to electrify the line when the necessary funds can be secured. Both the Nanking and Mukden lines were built by the viceroys of the provinces in which these cities are situated, and are therefore the property of the province or city.

Taken in the order of their importance, the street railways of Shanghai consist of the lines of the Shanghai Electric Construction Company, Ltd., which serve the International Settlement; the lines of the Compagnie Française de Tramways et d'Eclairage Electriques, which serve the French concession; and a line built by a Chinese company in the Chinese territory which adjoins the native city and the French concession.

The lines of the International Settlement Railway were built under the terms of a franchise, granted Oct. 10, 1905, to Bruce, Peebles & Company, Ltd., of Edinburgh, Scotland, by the municipal council of the International Settlement. This franchise was subsequently transferred to the Shanghai Electric Construction Company. A royalty of 5 per cent on the gross receipts of the company is payable to the Council. The company pays municipal taxes on all its buildings, but not on the tracks, poles, overhead lines, or cars. The franchise also stipulated that the street railway company should take its electric current from the Council's electric station. The rates fixed, per kilowatt hour, with a minimum annual consumption of 1,250,000 kw-hr., were as follows: First 600,000 units, 3.22 cents; second 600,000 units, 3.08 cents; third 600,000 units, 2.95 cents. These initial rates were based upon an estimated production cost of 2.2 cents per unit, but it was found, during the second year that the line was in operation that the initial rates were too high, and the Council, upon application by the company, made a new arrangement with the company. This arrangement provides for a fixed charge of 64 taels per kilowatt year plus a flat rate of 1.5 tael cents per unit for each unit consumed. The result for a consumption of 2,750,000 units in 1912 was an over-all charge equal to 2.34 cents United States currency per unit.

Immediately after the signing of the franchise and contract for power, the Shanghai Electric Construction Company entered into a contract with Bruce, Peebles & Company, Edinburgh, for the construction of rail lines equivalent to 23.3 miles of single track with equipment, including cars, carhouse and repair shops with tools. In the way of rolling stock the contractors were required to supply sixty-five double-end cars, each to seat thirty-two persons, twelve first-class and twenty third-class, and each equipped with two 25-hp motors. It was specified that each car should develop a speed corresponding to 18 m.p.h. The contract price for the complete equipment was $1,348,020.

Service was inaugurated in March, 1908, and on March 1, 1913, the company was operating its cars over 9.16 miles of double track and 7.15 miles of single track, or an equivalent of 25.47 miles of single track. On that date sixty-five cars equipped with motors and thirty trailers were in service, with fifteen additional motor cars and ten trailers contracted for and to be delivered during the present year.

Passenger traffic has shown a steady and remarkable increase. In 1909, 11,772,715 persons were carried; in 1910, 18,751,215; in 1911, 27,257,250; and in 1912, 40,734,233.

The French concession system was built and is operated by the Compagnie Française de Tramways et d'Eclairage Electriques de Shanghai, quite independent of the lines in the International Settlement, though joint running rights have recently been arranged and several joint circular routes instituted. The gage and rails are the same as on the International Settlement lines; and the cars on both lines are of about the same size and design. The running of cars began in May, 1908, and there are now in service, on the 10½ miles of track owned by the company, twenty-eight motor cars and four trailers, with an additional ten motor cars and eight trailers ordered in Europe. Direct current at 550/600 volts is used for traction, and the cars are equipped with Bruce-Peebles motors and controllers. The overhead trolley is used throughout the system.

In 1912 the car mileage was 980,342, and the number of passengers carried was 12,299,708, or 12½ passengers per car-mile. As on the International Settlement lines, both first and third-class passengers are carried, and here also the fares are charged by sections, third-class paying from 1 to 4 cents United States currency and first-class from 1½ to 7½ cents, according to the distance traveled.

The increase in traffic is shown by a comparison of the average number of passengers carried per day in the past four years. In 1909 it was 12,300; in 1910, 19,760; in 1911, 23,200; and in 1912, 33,700. The company's gross receipts from the street railway were $58,563 in 1909; $78,711 in 1910; $92,376 in 1911; and $121,032 in 1912, loss by exchange not deducted. Working expenses in 1912 were $74,590, leaving a profit for the year of $46,442, as against $26,689 in 1911, and $18,535 in 1910; while in 1909, a loss of $1,673 was sustained.

The Inland Electric Company, which is owned and controlled entirely by Chinese, for some years has been operating an electric lighting station and waterworks to supply the native city of Shanghai. The company's street railway line is being built under a franchise granted by the municipal authorities of the native city, the main features of which are an annual payment by the company of 3 per cent of its gross earnings in lieu of taxes, and the retention by the municipality of the right to purchase the entire plant at the end of thirty years, at an assessed valuation. The company is capitalized at about $98,000 United States currency.

Construction was begun only in January, 1913, but the laying of the first line of rails was completed in April, and the management hoped to have some cars running in June. The line extends from a point on the Chinese Bund, near the east gate of the native city, southward along the bank of the Whangpoo River for about 2 miles, and then turns west to the station of the Hangchow Railway, a total distance of about 3 miles. The railway station is the present southern terminus; but it is proposed soon to extend the line in a southwesterly direction to the large Kiangnan arsenal and eventually to the hamlet of Siang Fah. The east gate, or northern terminus, connects with the French street railway. The line is laid with grooved girder rails of German manufacture, weighing 90 lb. per yard, and the gage is 1 m.—the same as the lines in the

International Settlement and the French concession. The rails are laid upon beds of broken stone, 1 ft. wide and 8 in. thick, with concrete blocks under the rail joints, and tie rods spaced about 25 ft. The overhead feeder is carried on three-section iron tubular poles 18 ft. above ground.

Twelve cars, with 25-hp motors of 450/500 volts, and six trailers were being built for the company in the shops of Nicholas Tsu. These are of the same general design as the cars in use on the International Settlement and French street railways, and the trucks, motors, controllers, and other electrical fittings have been imported from England. The Chinese management expects to arrange joint running rights with the French company, and also, possibly, with the International Settlement company; or the Chinese line may eventually be leased to the French company for operation. The latter arrangement would avert a threatened paralleling of lines in one district. The French concession extends, on the south, up to the wall of the native city, and the French company has built a line which follows the wall almost from the west to the east gate. This wall is now being leveled, and the franchise of the Chinese company authorizes the building of a line just within the site of the wall all around the native city. Such a line would, of course, parallel the French line from the west to the east gate.

The Tientsin tramways, with the auxiliary lighting plant, are the outcome of an agreement, made in 1904, between a Belgian syndicate (represented by E. Meyer & Company, of Tientsin) and the then viceroy of Chili Province, H. E. Yuan Shih Kai. By the terms of this agreement the syndicate was authorized to construct a meter-gage electric street railway in and about the native city of Tientsin and to install a lighting system within the native city.

In addition to the line around the native city and in other Chinese territory, the company's lines extend through the Japanese, Russian, Italian, Austrian, and French concessions, with the Settlement railway station and bund as termini. The double-track line which runs about the native city is laid upon a boulevard which was built at the close of the Boxer outbreak upon the site of the old city wall, which was razed at that time.

Construction work was begun in 1904, and regular service of street cars and lighting commenced in 1906. At present the company has a total of 7¾ miles of double track line laid with rails of grooved girder pattern weighing 92 lb. per yard. The rails, which are 19.7 yd. in length, are laid upon broken limestone beds, with tie-rods spaced 5 ft., and are double bonded. The wires are carried upon 19 ft. tubular iron poles, which on wide streets are set between the two tracks and on narrow streets on one side. The roadway between the rails and for 19 in. on each side is stone flagged, and maintained at the company's expense.

Service is maintained by sixty-six motor cars and fifty trailers. All of the motor cars and some of the trailers were imported complete from Belgium and Germany; but the wooden bodies of newer trailers have been built in the company's shops, upon designs which have been found more suitable to local conditions. For the sake of cleanliness, the cloth window curtains and seat upholstery have been entirely eliminated and wooden seats substituted. Moreover, as the costume of both Chinese men and women makes a high step very difficult, the floor of the new trailers is only as high as the axles, with a single step at the entrance. The new trailers have no platforms or doors at the ends of the car, entrance and exit being by double side doors which are kept locked while the car is in motion. Each car seats sixty persons, and each platform of the motor cars carries eight to ten more, a small railed-off inclosure being reserved for the motorman. With minor exceptions, the entire route is double-tracked, and the service fairly frequent.

On an average, 2,000,000 passengers are carried per month. In former years an attempt was made to reserve a small section of each car for first-class passengers at an extra fare, but this has been abandoned, owing to lack of patronage, and only one class is now maintained. On the line around the native city the fare for a journey from the east to the west gate (one-half of the circumference of the city, or about 1½ miles) is 8 mills United States currency; while on the longer line, which passes through the foreign concessions, the fare is 1 cent for a maximum distance of 3½ miles. As copper coins are considerably depreciated in relation to the silver currency, the company posts in its cars rates of exchange between the two; and a passenger who, for example, tenders a silver Mexican or Peiyang dollar in payment of his fare is entitled to receive, say, sixteen silver 10-cent pieces and some odd coppers in change, dedepending upon the exchange rate for the day. The company estimates its loss on copper coin at 30 per cent, and as Chinese silver also fluctuates in value in relation to European currency, a further loss may be suffered. For instance, the company must exchange 130 to 135 copper cents for one Mexican dollar, and then the value of the Mexican dollar may sink from, say, 2s. 2d. to 2s., or even lower.

Direct current at 550/600 volts is employed for the street railway service. The older motors and controllers are from Siemens & Schuckert, Berlin; but the more recently imported motors and controllers have been purchased from the Ateliers des Constructions Electriques de Charleroi, Belgium. For the locally built trailers, wheels and axles only are imported.

The company provides small Chinese-style houses for the workmen, rent free; and a free bathhouse is maintained, daily baths for motormen and conductors being compulsory. Wages are paid as follows, per month: carpenters, $6.70 to $7.70 United States currency; fitters, $6.70 to $9.25; machine hands, $6.15 to $7.70; smiths and plate workers, $6.70 to $8.25; electricians, $7.70 to $10.25. These wages are of course only for Chinese workmen, the European foreman and instructors being very liberally paid.

The paid-up capital of the company is $1,206,250, and the first dividend of 4 per cent per annum was paid to stockholders in 1912, after five years of operation without any return to the shareholders. The dividend for 1913 was 6 per cent and a steady progress is anticipated for the future.

COMPANY PUBLICATIONS

The number of companies which issue publications in the interest of their employees or in the combined interest of the public and their employees has increased steadily in recent years. Naturally some of these are much more pretentious than others. Their contents vary with the purpose for which the particular publication is issued. Many of the publications intended for distribution among the public have gained quite a following. On the opposite page there are reproduced in one engraving nine typical pages from such publications, showing the varied ways in which the matter of public relations and the best interests of the employees are sought to be conserved through the medium of some of these publications.

President Marks, of the Borough of Manhattan, New York City, returned recently from a trip which he made to the cities of the East to study public market conditions. He inquired particularly into the matter of handling foodstuffs in cities by electric railways. He was impressed by the market terminal in Philadelphia, to which farm produce is brought by trolley. Mr. Marks was quoted as saying that he had suggested to officers of the Brooklyn Rapid Transit System the establishment of a similar system of delivery in Brooklyn. He expressed himself as convinced that the city must make every effort to have the railroads and the electric railways develop the market terminals in Greater New York.

CO-OPERATION SPELLS SUCCESS.

Ontario Safety Lead Is Showing the Way to Michigan in Safety Movement.

From the standpoint of public and organization co-operation the province of Ontario—and it hurts our pride to say it—is showing the way to Michigan in the SAFETY FIRST movement. Individually, many corporations in this state, including railways, manufacturers and others, are doing splendid work in the campaign, the state superintendent of public instruction is giving excellent assistance in the education of the children, and there are hopeful signs that the movement will spread in all lines of activity. But we are still far behind Ontario in the co-operative efforts which are essential if the fullest measure of success is to be obtained.

The Ontario Safety League was organized late last year at the suggestion of the Ontario Railway and Municipal Board. Its chief aim is to teach the public at large to think of SAFETY as the chief consideration. Some of the organizations included in the League are the Board of Trade, City Council, Board of Education, Separate School Board, Playgrounds Association, Team Owners' Association, Builders' Exchange, Police Commissioners and District Labor Council of Toronto, Ontario Sunday School Association, Ontario Motor League, Canadian Manufacturers' Association, steam and electric railways and the press.

Combined these organizations are doing a remarkable work in protecting the public, educating the children and minimizing injuries to employes. The League's accomplishments within the comparatively short time of its existence is an object lesson in what may be done through general and hearty co-operation.

We need a similar organization in Michigan.

Every time election comes closer politicians who have not anything to say about their political program, take root on the D. U. R. and hit right and left. Once the election is over everybody minds his own business and the D. U. R. continues to have peace and operate its cars.—La Tribuna Italiana of Detroit.

Commenting on the first anniversary of ELECTRIC RAILWAY SERVICE, the Dearborn Independent says: "It has done some good, too, in exposing the insincerity of some D. U. R. baiters."

ST. LOUIS EXCURSION.

There will be an excursion to St. Louis, Mo., Saturday, June 27, over the D. M. & T. electric line to Toledo and over the Clover Leaf from Toledo to St. Louis. The fare for the round trip is $7.50, good returning the following Tuesday.

The Rapid Railway waiting room at Port Huron is now located on the west side of Military street, two doors north of the Elks' temple.

WHO'S WHO IN THE D. U. R.

CLYDE FURLONG,
Assistant Superintendent, Flint Division.

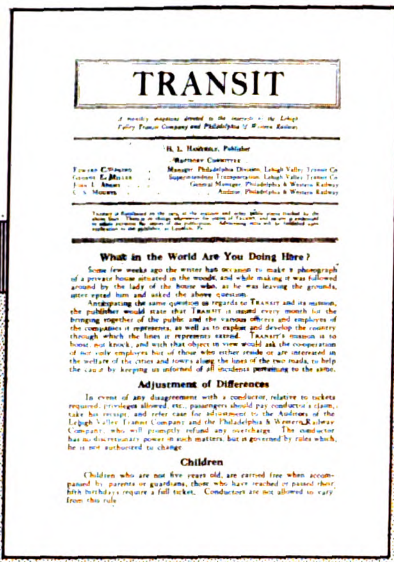
ATTACKS "SIDE-SADDLERS."

Thinks End-Seat Hog Is a "Chesterfield" Compared to the Other Species.

To the Editor: Permit me to make this suggestion. You would certainly be doing the general public an inestimable service if you could by a campaign of education through your widely read little weekly paper eliminate that most annoying of public pests, namely, the street car patron that will occupy a seat with one leg thrown over the other, and his feet sticking out about three feet in the aisle so as to give every man and woman a splendid opportunity to clean off the sole of his dirty boot with their clothing.

The end-seat hog is a "Chesterfield" compared to this individual.

FRANK R. HAMBURGER.



TRANSIT

A monthly magazine devoted to the interests of the Lehigh Valley Transit Company and Philadelphia & Western Railway

C. S. [illegible] . . . Auditor, Philadelphia & Western Railway

[illegible]

What in the World Are You Doing Here?

Some few weeks ago the writer had occasion to make a photograph of a private house situated in the woods, and while making it was followed around by the lady of the house who, as he was leaving the grounds, intercepted him and asked the above question.

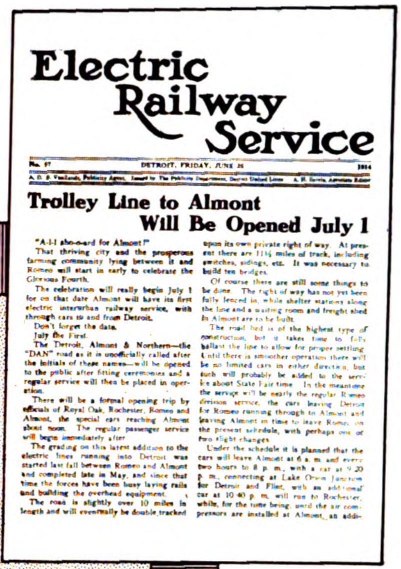
Anticipating the same question as regards to TRANSIT and its mission, the publisher would state that TRANSIT is issued every month for the bringing together of the public and the various officers and employes of the companies it represents, as well as to exploit and develop the country through which the lines it represents extend. TRANSIT'S mission is to boost, not knock, and with that object in view would ask the co-operation of not only employes but of those who either reside or are interested in the welfare of the cities and towns along the lines of the two roads, to help the cause by keeping us informed of all incidents pertaining to the same.

Adjustment of Differences

In event of any disagreement with a conductor, relative to tickets required, privileges allowed, etc., passengers should pay conductor's claim, take his receipt, and refer case for adjustment to the Auditors of the Lehigh Valley Transit Company and the Philadelphia & Western Railway Company, who will promptly refund any overcharge. The conductor has no discretionary power in such matters, but is governed by rules which he is not authorized to change.

Children

Children who are not five years old, are carried free when accompanied by parents or guardians; those who have reached or passed their fifth birthdays require a full ticket. Conductors are not allowed to vary from this rule.



Electric Railway Service

No. 57 DETROIT, FRIDAY, JUNE 26 1914

A. D. B. VanZandt, Publicity Agent. Issued by The Publicity Department, Detroit United Lines. A. H. [illegible], Associate Editor

Trolley Line to Almont Will Be Opened July 1

"A-l-l abo-o-ard for Almont!"

That thriving city and the prosperous farming community lying between it and Romeo will start in early to celebrate the Glorious Fourth.

The celebration will really begin July 1 for on that date Almont will have its first electric interurban railway service, with through cars to and from Detroit.

Don't forget the date.

July the First.

The Detroit, Almont & Northern—the "DAN" road as it is unofficially called after the initials of these names—will be opened to the public after fitting ceremonies and a regular service will then be placed in operation.

There will be a formal opening trip by officials of Royal Oak, Rochester, Romeo and Almont, the special cars reaching Almont about noon. The regular passenger service will begin immediately after.

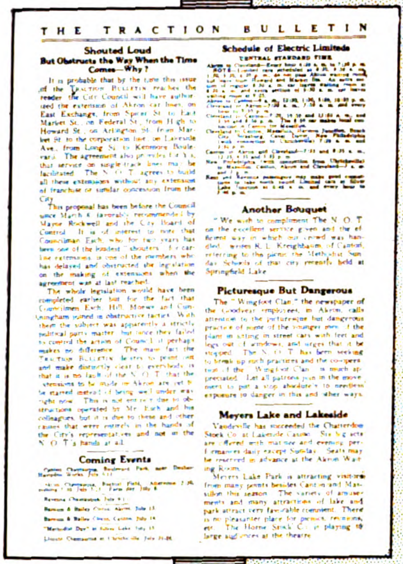
The grading on this latest addition to the electric lines running into Detroit was started last fall between Romeo and Almont and completed late in May, and since that time the forces have been busy laying rails and building the overhead equipment.

The road is slightly over 10 miles in length and will eventually be double tracked upon its own private right of way. At present there are 11¼ miles of track, including switches, sidings, etc. It was necessary to build ten bridges.

Of course there are still some things to be done. The right of way has not yet been fully fenced in, while shelter stations along the line and a waiting room and freight shed in Almont are to be built.

The road bed is of the highest type of construction, but it takes time to fully ballast the line to allow for proper settling. Until there is smoother operation there will be no limited cars in either direction, but such will probably be added to the service about State Fair time. In the meantime the service will be nearly the regular Romeo division service, the cars leaving Detroit for Romeo running through to Almont and leaving Almont in time to leave Romeo on the present schedule, with perhaps one or two slight changes.

Under the schedule it is planned that the cars will leave Almont at 6 a. m. and every two hours to 8 p. m., with a car at 9.20 p. m., connecting at Lake Orion Junction for Detroit and Flint, with an additional car at 10.40 p. m. will run to Rochester, while, for the time being, until the air compressors are installed at Almont, an addi-



THE TRACTION BULLETIN

Shouted Loud
But Obstructs the Way When the Time Comes—Why?

It is probable that by the time this issue of the TRACTION BULLETIN reaches the reader the City Council will have authorized the extension of Akron car lines, on East Exchange, from Spicer St. to East Market St., on Federal St., from High to Howard St., on Arlington St., from Market St. to the corporation line, on Lakeside Ave., from Long St. to Kenmore Boulevard. The agreement also provides for Ys, that service on single-track lines may be facilitated. The N. O. T. agrees to build all these extensions without any extension of franchise or similar concession from the City.

This proposal has been before the Council since March 6, favorably recommended by Mayor Rockwell and the City Board of Control. It is of interest to note that Councilman Esch, who for two years has been one of the loudest "shouters" for car line extensions, is one of the members who has delayed and obstructed the legislation on the making of extensions when the agreement was at last reached.

The whole legislation would have been completed earlier but for the fact that Councilmen Esch, Hill, Moewe and Cunningham joined in obstructive tactics. With them the subject was apparently a strictly political party matter, but since they failed to control the action of Council it perhaps makes no difference. The main fact the TRACTION BULLETIN desires to point out and make distinctly clear to everybody is that it is no fault of the N. O. T. that the extensions to be made in Akron are yet to be started instead of being well under way right now. This is not entirely due to obstructions operated by Mr. Esch and his colleagues, but it is due to these and other causes that were entirely in the hands of the City's representatives and not in the N. O. T.'s hands at all.

Coming Events

Canton Chautauqua, Boulevard Park, near Dueber Hampden Works, July 5-12.
Akron Chautauqua, Buchtel Field, Afternoons 2:30, evening 7:30, July 5-11. Farm day July 8.
Ravenna Chautauqua, July 9-1[illegible].
Barnum & Bailey Circus, Akron, July 13.
Barnum & Bailey Circus, Canton, July 14.
"Methodist Day" at Silver Lake, July 15.
Lincoln Chautauqua at Uhrichsville, July 21-26.

Schedule of Electric Limiteds

CENTRAL STANDARD TIME

[illegible]

Another Bouquet

"We wish to compliment The N. O. T. on the excellent service given and the efficient way in which our crowd was handled," writes R. L. Kreighbaum, of Canton, referring to the picnic the Methodist Sunday Schools of that city recently held at Springfield Lake.

Picturesque But Dangerous

The "Wingfoot Clan," the newspaper of the Goodyear employees, in Akron, calls attention to the picturesque but dangerous practice of some of the younger men of the plant in sitting in street cars with feet and legs out of windows, and urges that it be stopped. The N. O. T. has been seeking to break up such practices and the cooperation of the "Wingfoot Clan" is much appreciated. Let all patrons join in the movement to put a stop absolutely to needless exposure to danger in this and other ways.

Meyers Lake and Lakeside

Vaudeville has succeeded the Chatterton Stock Co. at Lakeside Casino. Six big acts are offered with matinee and evening performances daily except Sunday. Seats may be reserved in advance at the Akron Waiting Room.

Meyers Lake Park is attracting visitors from many points besides Canton and Massillon this season. The variety of amusements and many attractions of lake and park attract very favorable comment. There is no pleasanter place for picnics, reunions, etc. The Horne Stock Co. is playing to large audiences at the theatre.

[illegible]

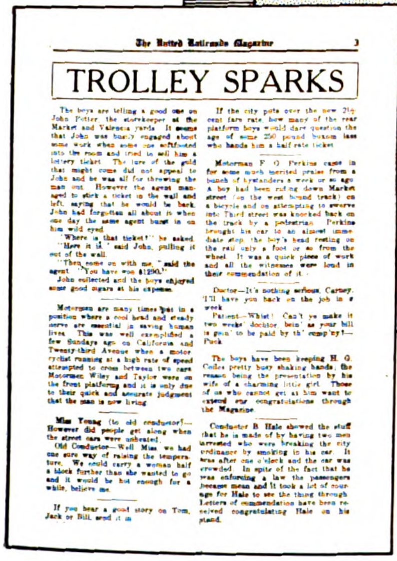
May, 1914 THE TRAMWAY BULLETIN 25

The four men of the Line Department who were fortunate in finding the mis-spelled word in an advertisement of the April Bulletin were Wm. H. Rhodes, wagon foreman, 60 West Maple street, first; O. P. Moran, 4613 West Thirty-third avenue, second; F. C. Robertson, emergency lineman, 923 East Cedar, third, and R. McKeehan, 3335 West Twenty-ninth avenue, fourth.

Each man was given a letter of introduction to Mr. Godfrey Schirmer, president of the German American Trust Company, entitling him to the offer contained in their advertisement.

Mr. Rhodes stated that he first looked for



The United Railroads Magazine 3

TROLLEY SPARKS

The boys are telling a good one on John Potter, the storekeeper at the Market and Valencia yards. It seems that John was busily engaged about some work when some one pussyfooted into the room and tried to sell him a lottery ticket. The lure of the gold that might come did not appeal to John and he was all for throwing the man out. However the agent managed to stick a ticket in the wall and left, saying that he would be back. John had forgotten all about it when one day the same agent burst in on him wild eyed.

"Where is that ticket?" he asked.

"Here it is," said John, pulling it out of the wall.

"Then come on with me," said the agent. "You have won $1250."

John collected and the boys enjoyed some good cigars at his expense.

Motormen are many times put in a position where a cool head and steady nerve are essential in saving human lives. This was well exemplified a few Sundays ago on California and Twenty-third Avenue when a motorcyclist running at a high rate of speed attempted to cross between two cars. Motormen Wiley and Taylor were on the front platforms and it is only due to their quick and accurate judgment that the man is now living.

Miss Young (to old conductor)—However did people get along when the street cars were unheated.

Old Conductor—Well Miss, we had one sure way of raising the temperature. We could carry a woman half a block further than she wanted to go and it would be hot enough for a while, believe me.

If you hear a good story on Tom, Jack or Bill, send it in.

If the city puts over the new 2½-cent fare rate, how many of the rear platform boys would dare question the age of some 250 pound buxom lass who hands him a half rate ticket.

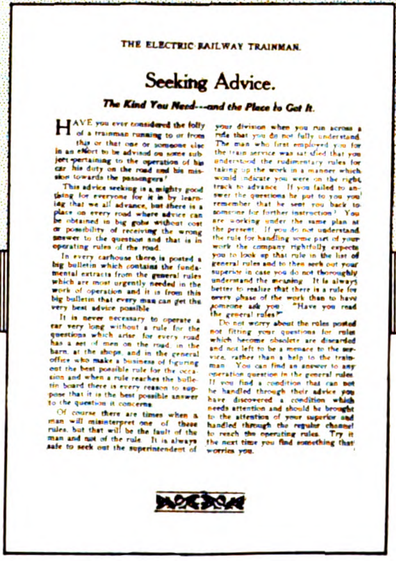
Motorman F. O. Perkins came in for some much merited praise from a bunch of bystanders a week or so ago. A boy had been riding down Market street (on the west bound track) on a bicycle and on attempting to swerve into Third street was knocked back on the track by a pedestrian. Perkins brought his car to an almost immediate stop, the boy's head resting on the rail only a foot or so from the wheel. It was a quick piece of work and all the witnesses were loud in their commendation of it.

Doctor—It's nothing serious, Carney. I'll have you back on the job in a week.

Patient—Whist! Can't ye make it two weeks' dochtor, bein' as your bill is goin' to be paid by th' comp'ny!—Puck.

The boys have been keeping H. G. Coiles pretty busy shaking hands, the reason being the presentation by his wife of a charming little girl. Those of us who cannot get at him want to extend our congratulations through the Magazine.

Conductor B. Hale showed the stuff that he is made of by having two men arrested who were breaking the city ordinance by smoking in his car. It was after one o'clock and the car was crowded. In spite of the fact that he was enforcing a law the passengers became mean and it took a lot of courage for Hale to see the thing through. Letters of commendation have been received congratulating Hale on his stand.



THE ELECTRIC RAILWAY TRAINMAN.

Seeking Advice.

The Kind You Need—and the Place to Get It.

HAVE you ever considered the folly of a trainman running to or from this or that one or someone else in an effort to be advised on some subject pertaining to the operation of his car, his duty on the road and his mission towards the passengers?

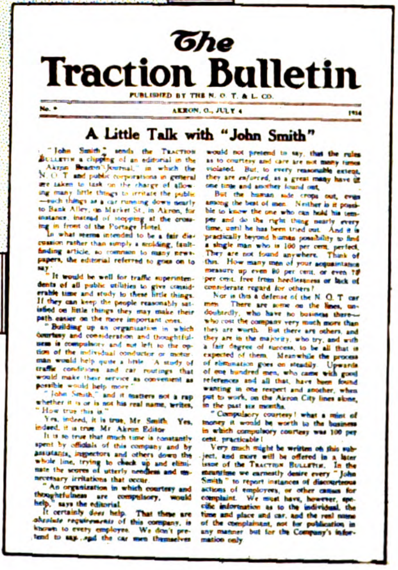
This advice seeking is a mighty good thing for everyone for it is by learning that we all advance, but there is a place on every road where advice can be obtained in big gobs without cost or possibility of receiving the wrong answer to the question and that is in operating rules of the road.

In every carhouse there is posted a big bulletin which contains the fundamental extracts from the general rules which are most urgently needed in the work of operation and it is from this big bulletin that every man can get the very best advice possible.

It is never necessary to operate a car very long without a rule for the questions which arise for every road has a set of men on the road, in the barn, at the shops, and in the general office who make a business of figuring out the best possible rule for the occasion and when a rule reaches the bulletin board there is every reason to suppose that it is the best possible answer to the question it concerns.

Of course there are times when a man will misinterpret one of these rules, but that will be the fault of the man and not of the rule. It is always safe to seek out the superintendent of your division when you run across a rule that you do not fully understand. The man who first employed you for the train service was satisfied that you understood the rudimentary rules for taking up the work in a manner which would indicate you were on the right track to advance. If you failed to answer the questions he put to you you remember that he sent you back to someone for further instruction? You are working under the same plan at the present. If you do not understand the rule for handling some part of your work the company rightfully expects you to look up that rule in the list of general rules and to then seek out your superior in case you do not thoroughly understand the meaning. It is always better to realize that there is a rule for every phase of the work than to have someone ask you: "Have you read the general rules?"

Do not worry about the rules posted not fitting your questions for rules which become obsolete are discarded and not left to be a menace to the service, rather than a help to the trainman. You can find an answer to any operation question in the general rules. If you find a condition that can not be handled through their advice you have discovered a condition which needs attention and should be brought to the attention of your superior and handled through the regular channel to reach the operating rules. Try it the next time you find something that worries you.



The Traction Bulletin

PUBLISHED BY THE N. O. T. & L. CO.

No. 9 AKRON, O., JULY 4 1914

A Little Talk with "John Smith"

"John Smith," sends the TRACTION BULLETIN a clipping of an editorial in the Akron Beacon Journal, in which the N. O. T. and public corporations in general are taken to task on the charge of allowing many little things to irritate the public—such things as a car running down nearly to Bank Alley, on Market St., in Akron, for instance, instead of stopping at the crossing in front of the Portage Hotel.

In what seems intended to be a fair discussion rather than simply a scolding, fault-finding article, so common to many newspapers, the editorial referred to goes on to say:

"It would be well for traffic superintendents of all public utilities to give considerable time and study to these little things. If they can keep the people reasonably satisfied on little things they may make their path easier on the more important ones.

"Building up an organization in which courtesy and consideration and thoughtfulness is compulsory and not left to the option of the individual conductor or motorman would help quite a little. A study of traffic conditions and car routings that would make their service as convenient as possible would help more."

"John Smith," and it matters not a rap whether it is or is not his real name, writes, "How true this is."

Yes, indeed, it is true, Mr. Smith. Yes, indeed, it is true, Mr. Akron Editor.

It is so true that much time is constantly spent by officials of this company and by assistants, inspectors and others down the whole line, trying to check up and eliminate the scores of utterly needless and unnecessary irritations that occur.

"An organization in which courtesy and thoughtfulness are compulsory, would help," says the editorial.

It certainly *does* help. That these are *absolute requirements* of this company, is known to every employee. We don't pretend to say, and the car men themselves would not pretend to say, that the rules as to courtesy and care are not many times violated. But, to every reasonable extent, they are *enforced*, as a great many have at one time and another found out.

But the human side crops out, even among the best of men. Neither is it possible to know the one who can hold his temper and do the right thing nearly every time, until he has been tried out. And it is practically beyond human possibility to find a single man who is 100 per cent. perfect. They are not found anywhere. Think of this. How many men of your acquaintance measure up even 80 per cent. or even 75 per cent. free from heedlessness or lack of considerate regard for others?

Nor is this a defense of the N. O. T. car men. There are some on the lines, undoubtedly, who have no business there—who cost the company very much more than they are worth. But there are others, and they are in the majority, who try, and with a fair degree of success, to be all that is expected of them. Meanwhile the process of elimination goes on steadily. Upwards of one hundred men, who came with good references and all that, have been found wanting in one respect and another, when put to work, on the Akron City lines alone, in the past six months.

"Compulsory courtesy! what a mint of money it would be worth to the business in which compulsory courtesy was 100 per cent. practicable!

Very much might be written on this subject, and more will be offered in a later issue of the TRACTION BULLETIN. In the meantime we earnestly desire every "John Smith" to report instances of discourteous actions of employees, or other causes for complaint. We must have, however, specific information as to the individual, the time and place and car, and the real name of the complainant, not for publication in any manner but for the Company's information only.

ILLUSTRATIONS OF NINE TYPICAL PAGES OF RAILWAY COMPANY PUBLICATIONS

LONDON T. O. T. MUTUAL AID WAR FUND

The publicity committee of the T. O. T. (tramway, omnibus and tube) mutual aid fund in London has begun the publication of the "*Fortnightly News*," which is to be the organ of the subscribers to the fund and the recipients of the relief. The committee expects to publish any items of interest, letters from the front, special experiences, incidents of relief, and suggestions for increased efficiency that readers furnish to the officers. It is now preparing a full list of reservists and volunteers who are in the army, and it plans to give not only the names but as far as possible the corps and the regiment to which each man belongs. The first and third pages of the first issue are reproduced herewith.

The number of men who left the employ of the T. O. T. companies to go to the front is more than 4000 and is constantly increasing. Wives, children and other dependents number about 12,000. War allowances seemed to require some time to reach the recipients, so the T. O. T. mutual aid fund was organized to make immediate provision. Already the fund has distributed more than £6,000. The plan provides that for every penny given by the employees remaining in service an equal allowance is made by the companies, who will also bear the cost of distribution. Furthermore, concerts and football matches are being planned as means of supplementing the fund. Visiting in different districts to investigate cases and give the help needed is done by representatives elected at each garage and depot, in addition to members of the executive committee. Dependents can also secure aid by communicating directly with the secretary.

Fortnightly News

No. 1 SATURDAY, SEPTEMBER 19th. 1914

MUTUAL AID SERIES

REPORTING PROGRESS OF THE FUND FOR WAR RELIEF.

The number of men who have left the employ of the T.O.T Companies to go to the War is over 4,000 and is continually increasing. Their wives, children and other dependents number about 12,000, and for these the T.O.T Mutual Aid Fund was promptly organised to make immediate provision.

NOTES ON NEWS.

Not a single day's hardship ought to be suffered by those left behind, when the bread-winner is suddenly called to arms to defend our country, and as soon as war demanded that 4,000 men in the service of the T.O.T. Co's. should shoulder a rifle, or devote their special skill to the work of the Motor Transport Corps, it was accepted as a non-stop duty to look after their wives and children without delay. War Office allowances and allotments seem to take some time to reach the recipients. T.O.T. relief filled the gap and had soon distributed over £6000.

Part of this has been or will be repaid, as it was merely advanced to meet immediate necessity. The regular relief of dependents requires, however, a large sum weekly, and the Mutual Aid plan provides that every penny given by the employees remaining in the service is doubled by an equal subscription from the Companies; who also bear all cost of administration. This should be nearly enough to keep the home together for comrades who are fighting their country's battles, but as a means of supplementing the fund, kindly help has been promised by Mr. F. Wall, Secretary of the Football Association, in sanctioning football matches on Chelsea and other grounds, and by Mr. Farren Soutar in organising concerts in districts served by the T.O.T.

The men remaining at work have responded generously to the appeal, and it will be a source of legitimate pride to all of us that the dependents of T.O.T. soldiers and sailors will need no help from public relief funds, which will be heavily drawn upon to help the families of reservists and volunteers in less fortunate circumstances. Not only do we want to keep our own peoples' dependents in reasonable comfort, but we want also to relieve any other anxieties. If they are in any sort of trouble in which they can be helped by legal or medical or general advice the committee will promptly assist them.

Visiting in different districts to investigate cases and give any help needed is done by representatives elected at each garage and depot, in addition to members of the executive committee. But dependents need not wait for visits if they require any advice or help. They should communicate at once with the Secretary of the T.O.T. Mutual Aid, York Mansions, Broadway, Westminster.

In this "Fortnightly News," which is the organ of the subscribers and recipients of relief, we want to publish any items of interest—letters from the front, special experiences and incidents of relief, suggestions for increased efficiency—that readers will be good enough to send to the offices. We want the "News" to be welcome and helpful to all the thousands of T.O.T people who are contributing to make our Mutual Aid scheme a model and a standard.

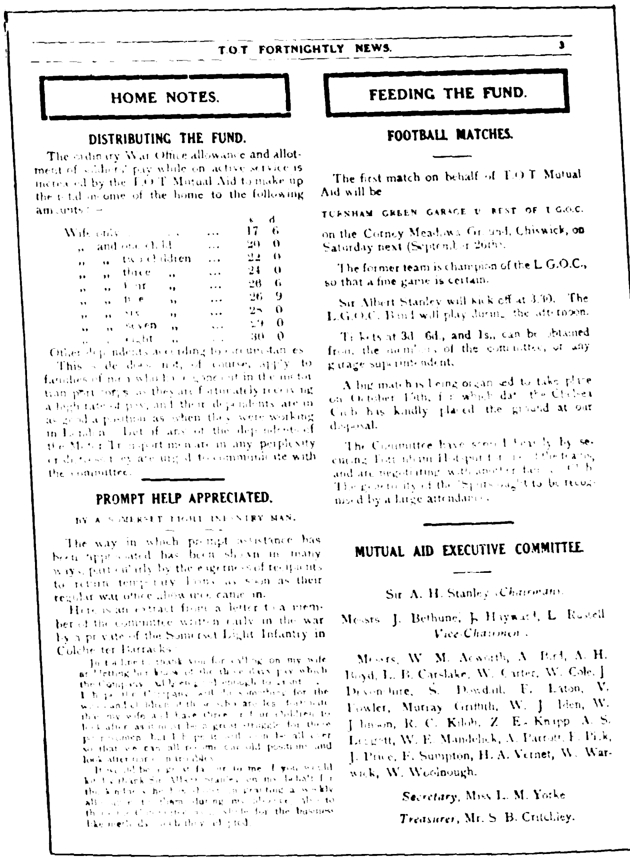
FIRST PAGE OF LONDON RAPID TRANSIT WAR ORGAN

The first issue contains interesting letters from three men in the thick of the fighting, relating their personal experiences on the battle line and expressing appreciation for the way in which dependents have been cared for by the transportation lines. Tables are also presented showing the total weekly income from war office allowances and T. O. T. mutual aid benefits, which ranges from 17s. 6d. for a wife only to 30s. for a wife and eight children. The subscription of employees for the week ended Sept. 12 amounted to £453 19s. 10d., which total is doubled by the subscription of the company. The average amount subscribed per head amounted to 5s. 1d. The South Metropolitan Company headed the list with 98 subscribers out of every 100 employees, but was closely followed by the Metropolitan Electric Tramways with 96 per cent, the Associated Equipment Company with 94 per cent and the Central London Railway with 93 per cent. The chairman of the mutual aid executive committee is Sir Albert H. Stanley, managing director of the London Underground Electric Railway, London United Tramways, Ltd., the Metropolitan District Railway and the London General Omnibus Company, Ltd.

BELL OR BUZZER CIRCUITS USED FOR TELEPHONING

Wouldn't it be more convenient to buzz and speak your instructions to the office boy or other subordinate and get the answer immediately without waiting for him to come to your desk?

The Western Electric Company is demonstrating a simple little outfit consisting of two hand telephone instruments called Interphones, which can be connected to any existing bell or buzzer circuit without any change in the bell, batteries or wiring and which transforms them into a practical working telephone system. With the old push button and bell system two trips were necessary, one to find out what was wanted, the other to carry out the instructions. With one of these Interphone outfits installed only one trip, if any, is necessary. The cost of one outfit is $8.75.



T.O.T FORTNIGHTLY NEWS. 3

HOME NOTES.

DISTRIBUTING THE FUND.

The ordinary War Office allowance and allotment of soldiers' pay while on active service is increased by the T.O.T Mutual Aid to make up the total income of the home to the following amounts:—

	s.	d.
Wife only ...	17	6
,, and one child ...	20	0
,, ,, two children ...	22	0
,, ,, three ,, ...	24	0
,, ,, four ,, ...	26	6
,, ,, five ,, ...	26	9
,, ,, six ,, ...	28	0
,, ,, seven ,, ...	29	0
,, ,, eight ,, ...	30	0

Other dependents according to circumstances.

This scale does not, of course, apply to families of men who have gone out in the motor transport corps, as they are fortunately receiving a high rate of pay, and their dependents are in as good a position as when they were working in London. But if any of the dependents of the Motor Transport men are in any perplexity or distress they are urged to communicate with the committee.

PROMPT HELP APPRECIATED.

BY A SOMERSET LIGHT INFANTRY MAN.

The way in which prompt assistance has been appreciated has been shown in many ways, particularly by the eagerness of recipients to return temporary loans as soon as their regular war office allowances came in.

Here is an extract from a letter to a member of the committee written early in the war by a private of the Somerset Light Infantry in Colchester Barracks:

Just a line to thank you for calling on my wife [illegible]

[illegible]

FEEDING THE FUND.

FOOTBALL MATCHES.

The first match on behalf of T.O.T Mutual Aid will be

TURNHAM GREEN GARAGE v. REST OF L.G.O.C.

on the Corney Meadows Ground, Chiswick, on Saturday next (September 26th).

The former team is champion of the L.G.O.C., so that a fine game is certain.

Sir Albert Stanley will kick off at 3.30. The L.G.O.C. Band will play during the afternoon.

Tickets at 3d., 6d., and 1s., can be obtained from the members of the committee, or any garage superintendent.

A big match is being organised to take place on October 10th, for which day the Chelsea Club has kindly placed the ground at our disposal.

The Committee have scored heavily by securing Tottenham Hotspur for one of the teams, and are negotiating with another famous club. The generosity of the 'Spurs ought to be recognised by a large attendance.

MUTUAL AID EXECUTIVE COMMITTEE.

Sir A. H. Stanley (*Chairman*).

Messrs. J. Bethune, J. Hayward, L. Russell (*Vice-Chairmen*).

Messrs. W. M. Acworth, A. Bird, A. H. Boyd, L. B. Carslake, W. Carter, W. Cole, J. Devonshire, S. Dowdall, F. Eaton, V. Fowler, Murray Griffith, W. J. Iden, W. Johnson, R. C. Kilby, Z. E. Knapp, A. S. Leggett, W. E. Mandelick, A. Parratt, F. Pick, J. Price, F. Sumpton, H. A. Vernet, W. Warwick, W. Woolnough.

Secretary, Miss L. M. Yorke.

Treasurer, Mr. S. B. Critchley.

AN INSIDE PAGE OF LONDON PAPER

GEAR TESTING

To see how the hardness of the gear teeth is measured and how the manufacturer is able to offer gearing that will meet difficult and special requirements is worth the acquaintance of every operator. At spaces 140 to 144, the R. D. Nuttall Company is giving such information. Each Nuttall gear and pinion before leaving the Nuttall gear plant at Pittsburgh, the largest in the world, it tested for hardness after heat treatment by means of a Shore sclerescope such as is exhibited. Again, special impact and abrasive machines are used by this company for testing the resistance of gearing to shock and wear.

GAS-ELECTRIC MOTOR CAR WITH LONG BAGGAGE COMPARTMENT AND 600-1200 VOLT MOTORS

The Spokane, Portland & Seattle Railway has contracted with the General Electric Company for a gas-electric motor car, which will be the first car of this type to be employed on this railway. It is the intention to place the car in operation between Portland and Rainier, Ore., on the Astoria-Columbia division of the road.

Steam trains are now making two round trips each way per day between these two cities, 45.8 miles apart: leaving Rainier at 7:40 a. m. arriving at Portland at 9:45 a. m., and leaving Portland at 12:50 p. m. arriving at Rainier at 2:40 p. m.; leaving Rainier at 3 p. m., arriving at Portland at 5 p. m. and leaving Portland at 5:35 p. m., arriving at Rainier at 7:25 p. m. The total distance for the four single trips per day is 183.2 miles. The gas-electric motor car will be required to haul regularly one 25-ton trailer seating 60 passengers. At times when traffic is heavy it may be necessary to haul two trailers of this capacity on both round trips.

The schedules of trains composed of the motor car and two trailers will be increased ten minutes each run, with stops of not more than thirty seconds. The maximum grade on this section of the railway is ½ per cent., extending over a distance of about 3 miles; but, in general, the road follows the Columbia river grade and is nearly level.

The Spokane, Portland & Seattle Railway runs from Spokane, Wash., through Portland, Ore., to Warrenton, Fort Stevens and Holladay on the coast. It connects with Seattle, Wash., over the Great Northern Railway and the Northern Pacific Railway. Other connecting lines are the Oregon Trunk Railway, Oregon Electric Railway and the United Railways. The road embraces a total of 556 miles, standard track gage. The rolling stock equipment comprises sixty-nine locomotives, ninety-eight passenger cars and 740 freight and miscellaneous cars.

The gas-electric motor car for this railway is what is known as type RE-70-B-21. The details of construction conform in general to those of the standard cars manufactured by the General Electric Company. The baggage room, however, is about twice the usual length in order to transport the large quantities of express handled, particularly the heavy shipments during the fruit season. The specific dimensions are 70 ft. 11-⅜ in. over bumpers by 10 ft. 6-⅜ in. wide over all. The car weighs approximately 51 tons and has a seating capacity for sixty-eight passengers. The interior is partitioned into four compartments. The cab in front containing the power plant apparatus measures 11 ft. 11 in. long; next is the baggage room, 20 ft. 10-⅞ in. long; then the smoking section, 12 ft. 6 in. long; and the passenger compartment, 20 ft. 5-⅞ in. long.

The car is equipped with two GE-205, 600-1200 volt, box-frame, oil-lubricated, series, commutating pole railway motors having a total of 200-hp capacity. The motors are mounted with nose suspension directly on the axles of the forward truck. They are insulated for 1200 volts so that they may be interchanged, if desired, with the motor equipments on the cars of the Oregon Electric Railway, which operates on the 1200-volt system. The generating unit consists of an eight-cylinder, four-cycle gas engine of the "V" type, direct-connected to a 600 volt, commutating pole electric generator, designed to meet the special conditions the service demands.

The body of the car is of the all-steel type of construction, except the seats and interior finish, which is of mahogany. A rear open platform entrance with body and platform railings is provided. The bearings and treads and flanges of the wheels conform to M.C.B. standards. The trucks are of the heavy spring bolster type with elliptic bolster and coil equalizer springs.

ELECTRIC RAILWAY DEVELOPMENT IN THE UNITED KINGDOM

Since 1878 the route length of tramways and light railways on public roads open for traffic in the United Kingdom has increased from 269 miles to 2662 miles. Capital expenditure increased from $20,475,068 to $386,203,761, and the number of passengers carried from 146,000,000 to 3,220,000,000, while the net receipts had grown from $1,123,947 to $27,194,590. The number of passengers carried in the year 1912-1913 was equal to about seventy-one times the estimated population of the United Kingdom. This figure, of course, is much lower than the annual per capita riding of the inhabitants of larger cities which may range from 200 to 300.

Of the total of 1818 miles of line owned by local authorities, 1617 miles are worked by the authorities themselves, or in a few cases by other local authorities leasing from them and the remaining 201 miles by leasing companies. The return also includes 15 miles of trackless trolley route worked by the owning local authorities. In 1913 the route mileage worked by electric traction was 2546 miles out of a total of 2662, as against 2518 out of 2637 in the preceding year, the remaining portion in 1912-1913 being 4.4 per cent of the total length of line. Of the 286 undertakings, 171 belonged to local authorities and 115 to companies or other parties. The net receipts of local authorities who worked tramway undertakings belonging to them, or leased from other local authorities, amounted to $19,932,794 on the year's traffic, and they applied $6,323,330 toward the reduction of tramway debt and $2,649,702 toward the public-tax fund, while carrying $3,634,054 to reserve and renewal funds. In the cases of four local authorities and seven companies, the returns for tramways showed an excess of working expenditure over gross receipts, while two trackless trolley systems also exhibited a deficiency. The return shows that in twenty-five cases it was necessary to seek aid from rates to meet some part of the charges for the year including interest and redemption of tramway debt. The total amount thus obtained was $316,264, as compared with $302,365 in the previous year.

The total number of passengers carried in 1912-1913 was 3,219,857,293 as against 3,127,318,732 in the preceding year, and the number of miles run by the cars 334,777,515 and 323,354,389, respectively. The capital expenditure per mile of single track open worked out at $66,797 last year for lines and works, and for all items at $88,711, as compared with $66,295 and $87,621, respectively, in 1911-1912. The percentage of net receipts to total capital outlay in 1912-1913 was 7.04, and to net capital outlay (eliminating amounts expended on construction or purchase of old lines and works superseded) 7.64, as against 7.5 and 8.15, respectively, in the previous year. The percentage of working expenditure to gross receipts last year was 62.68, against 60.6 in 1911-1912, and the number of passengers carried per mile of route open was 1,204,011, against 1,183,620 in the preceding year. The percentages of passengers carried per car mile were 9.62 and 9.67, and the average receipts per passenger $0.0213 and $0.0215. There was $2,649,702 paid in 1912-1913 in relief of taxes out of the profits of undertakings worked by local authorities, as compared with $2,377,329 in 1911-1912.

The miles of route open last year of tramways numbered 2,661.69, and of trackless trolley systems, 12.59, as against 2,637.95 and 5 miles of trackless trolley in 1911, 1912. Comparisons are also given of the steam period in 1898, when with 1,064.19 miles of route open 858,485,542 passengers were carried, and the number of miles run by cars was 90,593,716. In the horse period (1879) there were 321.27 miles of route open, and the total passengers carried numbered 150,881,515, while the miles run by cars aggregated 19,418,373. The average receipts per passenger in 1898 worked out at $0.0246 and in 1879 at $0.0368.

Among the Exhibits

The gear and pinion department of the E. W. Bliss Company, Brooklyn, N. Y., is represented at the convention by E. W. Stone.

* * *

The Mica Insulator Company, New York, has no exhibit this year. It is represented at the convention by Charles E. Coleman and Charles H. Bell.

* * *

W. H. Sauvage, president Sauvage Appliance Company and inventor of Sauvage shim slack adjuster and other car appliances, is present at the convention representing his own interests.

* * *

George E. Pratt, who for many years was a regular attendant at electric railway conventions, is back this year as a representative of the Railway Utility Company, of Chicago. It has an interesting exhibit of thermostats and ventilators.

* * *

George Sanford, railroad sales agent for the Parrott Varnish Company, Bridgeport, Conn., added one more to the large number of New York supply men attending the convention. He arrived Tuesday night and is stopping at the Marlborough-Blenheim.

* * *

The result of seven years' experimenting of Prof. Irving Fisher, connected with Yale University, to perfect a visible card index is shown in space 523. Manufacturers and railroad men from all parts of the United States have visited the booth and all are enthusiastic over the simplicity and easy access of this remarkable system.

* * *

G. T. Abel, Brooklyn, N. Y., painting specialist, is making his headquarters at the convention with the Columbia Machine & Malleable Iron Company, space 620. For twelve years Mr. Abel, with an experienced crew of painters has been engaged in contract car painting, doing work for electric railways in all parts of the country.

* * *

Frank Sheeran, representing J. J. McCabe's do-most-anything 2-in-1 lathe, is down here to tell everybody that while he has no lathe on exhibit there are plenty of them in railway shops hereabout. One of the nearest is in the shops of the New Jersey & Pennsylvania Traction Company at Trenton.

* * *

Full of years (160 of them) and honors, the F. W. Devoe & C. T. Reynolds Company is still in the business of making and selling paints and varnishes. C. G. Chamberlin, though not in at the founding of the company, is representing it among the electric railway trade to-day.

* * *

Harry M. Shaw and Frank H. Shaw, Newark Engineering Company, Newark, N. J., are attending the convention in the interest of their insulating specialties, overhead material, third-rail insulators and Shaw lightning arresters. The lightning arresters are shown at space 557 with the Lord Manufacturing Company exhibit. The American General Engineering Company, New York, is the general sales agent for this material.

* * *

George E. Austin, president American General Engineering Company, arrived Tuesday night to attend the convention. He is stopping at the Brighton. During the year his company has brought out a new motor-driven self-contained armature banding machine with automatic weighing tension feed. On this single machine one can band armatures, slot commutators, wind coils and grind commutators. The machine is four machines in one, designed to save space and secure economy in labor and accuracy of work done.

John C. Dolph, insulation specialist, Newark, N. J., arrived to attend the convention Wednesday morning. During the past year Mr. Dolph has developed a water-repellant acid and alkali-proof anti-corrosive preservative paint called "Universalak," especially adapted to preserve iron and steel surfaces exposed to the elements. He has also brought out "Synthite," a new type of synthetic insulating compound, moisture and acid-proof, especially adapted to withstand high temperatures. This can be used and applied by any shop mechanic by the brush-dipping or impregnating method.

THE "RADIAX" TRUCK BETTER THAN EVER

The J. G. Brill Company is exhibiting one of its "Radiax" type of trucks with a wheelbase of 11 ft. 6 in. This truck has a much simpler brake rigging than the one shown last year; it is designed on the same general principle as the body brake rigging of a double-truck car but is pivoted over the king pin at each end from which the motors radiate. The motor, axle and wheels, together with the brake beam, hangers and shoes, radiate as a unit from the same pivotal point. The truck is placed with one axle radiated to show the slight inclination of the links which form the connection between the journal box and the frame when on a curve; these links have hemispherical tops which move freely in socket castings placed on top of coil springs. At the bottom of each link are two pins or trunnions which engage in grooves under a yoke brace; when the truck enters a curve one of these pins immediately leaves its groove transferring the load to the other pin and thus setting up a powerful tendency to return to the normal position as soon as straight track is reached. The double pin arrangement has another important function in that it holds the car body steady on straight track. Attention is being called to the solid forged side frames of this truck which, in addition to their strength, have the advantage of permitting the body and frame springs to be placed where they will do the most good. The Third Avenue Company's low-level car on the Boardwalk opposite the Pier is mounted on a "Radiax" truck with 24 in. wheels; forty-nine of these trucks were furnished. It is learned that the Brill Company has received thirty-nine orders for "Radiax" trucks.

THE SAFETY OF THE PUBLIC

The Prepayment Car Sales Company, in space 414, has on exhibit several different types of door-operating mechanisms and safety features, and perhaps the working model of the door mechanisms as used on the stepless cars of the New York Railways Company best illustrates the safeguards available for insuring the safety of the public.

The operation of the door in opening and closing is controlled by an electric foot button switch operated at the prepayment position by the conductor. When the car motor is running (which is illustrated in the exhibit by a car motor controlled by a starting switch) the door cannot be opened by the foot-switch, although it can be opened at any time by an emergency switch. When the door is open, an interlocking switch prevents the car motor from being started. If the door touches a passenger in closing, the safety shoe on the edge of the door automatically reverses and opens the door until the door is clear of the passenger, when it instantly again recommences its closing movement. In these ways the safety of the public is safeguarded at every point.

In addition to this, every moment of time is saved to expedite the operating schedule of the car. The conductor can depress the door foot-switch before the car has stopped, and the moment it has stopped, but not before, the door will automatically open. The motorman can set his car-controller to running position while the door is open and the moment the door is closed, but not before, the car will start. In this way valuable time is saved to the railway.

PROGRAM FOR TO-DAY

CONVENTION MEETINGS

9:30 a.m. Meeting of Engineering Association, Engineers' Hall, Convention Pier.

ENTERTAINMENT

11:00 a.m. Morning Concert by Engel's Orchestra, Lobby, Convention Pier.

Responsibility of Investment Bankers

Valuable as has been the work of investment bankers in floating security issues and analyzing company and commission reports, as stated Wednesday by H. S. Swift, they have not yet rendered all of the service of which they are capable to the electric railway field. Their assistance and influence are still greatly needed in the matter of improving accounting procedure and in helping to establish a fair basis of regulation. Investment bankers presumably would like more uniformity in the distribution of maintenance and construction expenses and more detailed statements of construction expenditures, but if no action follows this desire the wish itself is of little help. On such points as these there is an urgent need for a closer union between the statistical departments of the investment banker and the accountants of the public utility company. For instance, a definitely expressed consensus of opinion of the investment houses as to what the ideal annual report should contain would be invaluable as indicating the investor's idea of corporate publicity. Bankers should also take greater interest than they have hitherto manifested in the subject of rate regulation. It is at the foundation of railway development and if unfair precedents are established the entire industry will suffer. Hence, whenever a rate or valuation case comes up affecting a public utility in a city in whose development a particular group of bankers are interested, even if they have no direct financial interest in the utility itself, they should make an effort to see that the regulatory body has all proper information. As a rule the banker is prominent in the civic life of the community in which he lives, and he is considered, and properly so, as a conservative and constructive factor in its financial affairs. He should make his influence felt in the encouragement of right financial thinking in connection with utilities which serve the town in which he lives. The field of investment bankers is wide, and their sources of statistics almost unlimited, but they could do much more while maintaining their sales activities, by applying the means at their disposal directly toward the solving of public utility problems.

The Parable of the Talents

The modern version of the Parable of the Talents, as told by L. R. Nash, of Stone & Webster, in the convention issue of this paper, has attracted considerable interest and comment at the convention. According to it the servant who buried the talent which had been entrusted to him and who consequently was able to return it without diminution to his master was better off than those who invested theirs in commercial undertakings. Their attempts to develop the public utilities of the day seemed at first successful. But this very success aroused the hostility and cupidity of the public, which, by drastic laws on rates, valuations, taxes and service requirements, so reduced the value of the investments that when labor troubles arose and higher wages had to be paid there was little or no equity left for the owners. The revised tale teaches an important lesson in regard to the rights of owners, and the result which will follow the elimination of all incentive to capital to enter the public utility field unless it is assured of adequate returns. There is no doubt that in many instances during the last few years the investor who followed the example of the third servant in the retold parable would have done better financially if he had followed the example of the other two servants. Nevertheless, if the reader should draw this conclusion as a general truth from Mr. Nash's parable he would be incorrect, and we are sure that there is no one who will admit the truth of this contention more willingly than Mr. Nash himself. Present laws may be defective, absurd theories in regard to capital may be current, injustice to capital may be prevalent, but the fundamental economic truth remains that those who invest their money in commercial undertakings to improve the condition of their fellows and render them a legitimate service deserve and will get greater compensation than those who refuse to do so. No community can progress, even if it can exist, on any other rule of conduct, and laws which attempt to enforce any other principle are bound to fail.

Compensation for Carrying United States Mail

The effort of the electric railways to secure adequate compensation for carrying mail matter seems likely at present to meet with success. It has been a long struggle because, strange as it may seem, it has been impossible to induce the Post-office Department to meet the electric roads on a business basis. The situation on the electric roads, certainly on the city roads, is entirely different from that on the steam roads. The latter furnish the only means of transportation for the mail. If the mails were not carried by them there would be no mail facilities along the line. In the cities, however, the Post-office Department can deliver the mail by wagon, automobile, hand or electric car. It is purely a matter of expediency as to which will be used. We have never been able to see any reason why a city electric railway should do this business below cost or for less than the price which it considers adequate. Several railway companies, as shown by the committee report, have taken the same view and have declined to carry any more mail. We are glad to see, however, that the Post-Office Department and also the congressional committees in charge of these matters are adopting a more rational view. The injustice of compelling the steam railroads to carry the mail below cost has been impressed upon the public, and a bill has now been introduced in Congress to make the pay to the steam railroads for mail carried more adequate. This reform is an excellent example of what can be done by an appeal to the sense of justice of the people. As a result of this step, it seems probable that a fair treatment will also be accorded to the electric roads. The active propaganda of the association committee during the year seems to be bearing fruit. The Senate committee has expressed itself as willing to consider reformatory measures, if their justice is proved by definite data. The industry is to be congratulated upon this result.

Conventionalities

Getaway Day! Makes you feel blue, doesn't it?

John P. Fox, the original bagman, is in our agitated midst.

All through the convention F. M. Loud of the Public Service Railway has been singularly quiet.

That Treat-Speed combination of the C. C. Smith properties is a dangerous one when turned loose in the Shelburne grill.

An esteemed contemporary reports that the Goldschmidt Thermit crowd has moved to the Hotel Ostend. Ostend invested by the Germans, as you might say.

J. A. Emery of Ford, Bacon & Davis, has left for a few days the engineering work on the new Philadelphia subway and elevated lines. He arrived yesterday with Mrs. Emery.

On Thursday William H. Wheaton, chief engineer of power stations and master mechanic of the Wilkes-Barre Railway, added to his numerous duties the pleasanter one of showing the exhibits to Mrs. Wheaton.

Boss Chubbuck of the I. T. S. has dropped his roll betting on E. A. MacNutt's skee-ball game. The latter could have beaten the record at one time on Wednesday if he had only rolled eight more balls into the fifty hole.

W. V. Dee of the entertainment committee has been in charge of its publicity work, and his humorous articles have been a feature of the work of getting out the Dailies. We have laughed heartily over Mr. Dee's compositions.

"Truly, sir, one of the things that ought to yield the greatest satisfaction to a person of eminent virtue is to live to see himself in good reputation with the world, and his actions published in print."—*Don Quixote.*

WANTED—Synonyms for the words: Showing, exhibiting, displaying, offering, presenting, bringing forth, providing, demonstrating, submitting, furnishing, producing, unfolding, supplying and proffering. Apply to editor of "Among the Exhibits."

J. L. Peacock, inventor of the famous Peacock brake, arrived in town on Wednesday morning to attend the convention. Besides his extensive interest in the brake business, he is also running a large ranch where he is raising little peacocks.

The neatly manicured brochures which are so frequently prepared by J. P. Ripley of J. G. White & Company remind one of the exhibits of axles. Some of the sentences in them are polished so that they make a looking-glass appear like a piece of emery cloth.

The Connecticut Company certifies to the presence of one more delegate, Thomas McGreevy of the auditing department. This increases the Connecticut delegation to thirty, and it claims, therefore, the largest number of delegates sent by any road within the well-known universe.

We were afraid that Tom AH Hay wouldn't get into the colyum this year until WO Hay, his brother, said he was suffering from his annual attack of litigiousness. Just like last year some cruel man dragged Tom into the courts at convention time—but we still hope he'll breeze in on Friday.

All of the officers and executive committee of the American Electric Railway Association are at the convention this year. For the last two or three years business has detained one or another from attendance. L. S. Storrs has been called back to New Haven, but he was here during the early part of the week.

The official list is doing stunts with the name of our old friend J. M. Bosenbury, superintendent of motive power and equipment of the Illinois Traction System. In the first list he appeared under the R's and in the second list he appeared nowhere. We are wondering how his name will appear in the list this morning.

L. R. McDonough, who has recently been appointed secretary to P. J. Kearny, electrical engineer of the electric division, New York, New Haven & Hartford Railroad, arrived Wednesday. He was formerly construction engineer under Charles Rufus Harte, who is well known by his activities in the work of the various associations and needs no introduction here.

Thomas E. Wood, master mechanic, Omaha, Council Bluffs Street Railway Company, Omaha, Neb., better known as "Old Tom" and noted as the leading orator of the Iowa Street & Interurban Association, claims that he is no longer interested in the exhibits, as he had made a complete examination of every detail in every booth on the pier by 7 a. m. on Monday morning.

W. T. Dougan, who was engineer of construction on the underground electric system of the old Metropolitan Railway in New York for nine years and engineer of maintenance of way on the same system (later the New York Railways) for eight years, is the latest railroad man to join the ranks of the peddlers, as he has just become president of the T. H. Reynolds Contracting Company.

Martin Schreiber risked his life recently (and that of one of the Public Service automobiles) in trying to get a company section organized in Allentown in time for the convention. One of his office staff who accompanied him returned by train a nervous wreck. We mention this merely to indicate how aggressive the association committeemen are.

As the convention draws to its inevitable close it seems fitting to speak of the efforts of the entertainment committee that have helped to make the convention such a success. Certainly these have been appreciated by the delegates and their guests, and we take the liberty of extending their thanks as well as our own to W. G. Kaylor, chairman of the committee and to his efficient assistants.

J. E. Duffy, general superintendent of the New York State Railways' Utica-Syracuse lines, and Elmer E. Strong, superintendent of transportation of the Rochester lines of the same property, have been seen so much together that five contributors have coupled their names in a wheeze to the effect that one invariably associates strength with Duffy, the latter being a well-known (to some) brand of Irish malt whiskey. We think its a bum wheeze, too.

A contributor (state of mind unknown) reports as follows: Manager Grayson is looking for a job. President Frank O. Grayson of the same company is very much in evidence at the convention looking after the various accounts which he handles in the Southwest. The story of Manager Grayson's dismissal follows: About ten days ago several "Friend Peddlers" of St. Louis, under the guise of directors of the company, which is wholly owned by Mr. Grayson, sent out notices to the trade that at an indignation meeting recently held Mr. Grayson had been dismissed for conduct unbecoming a general manager. The character of the charges as noted were such that the railway men receiving the notices, with a few exceptions, understood that a huge joke was being perpetrated on their old friend "Foggy." They heartily entered into the spirit of the thing and since then collect telegrams have been pouring into St. Louis depicting alleged hitherto unknown irregularities and misconduct. To bring about a climax to the fiasco a banquet of some proportions was arranged for and held under the auspices of the jokers a few nights ago. Grayson was forcibly carried to the banquet and after making him listen to verbal chastisement by a dozen or more of his closest friends he was presented with a loving cup and several other tokens of esteem. Frank says although he was worried at first over the action brought against him he has since been gratified to find several large orders from railway friends in the mill as a result of the excitement. Incidentally, he has an album full of censored poems which he is keeping in memory of the second anniversary of his firm's business.

THE NEW PRESIDENT

C. Loomis Allen, elected president of the American Electric Railway Association yesterday at the age of forty-four years, is remarkably well qualified for the position by temperament and experience. He has been actively interested in railway association work for so long that the duties of his new office will have no elements of novelty. The honor which comes to him has been well earned, for as third, second and first vice-president successively he has shouldered a lot of responsibility. Mr. Allen in his railroad career has shown that rare combination of executive ability and tact which should make his incumbency of the office of the greatest value to the association.

In a case like this the members of the railway public are desirous of knowing, or reviewing if they know already, the steps which have led to a man's elevation. Mr. Allen is a native of Syracuse, N. Y., where most of his life has been spent. He attended Alfred and Syracuse Universities and there laid the theoretical foundation for his practical work. His first work was practical enough, for he became axeman for the engineering department of the Norfolk & Western Railway. Thus introduced to the profession of civil engineering he served in more and more responsible positions until he felt equipped for independent work. He then joined T. H. Mather, and under the firm name of Mather and Allen, the two had charge of the civil engineering end of the electrification of the railways in Syracuse between 1892 and 1895.

C. LOOMIS ALLEN

For three years following Mr. Allen was civil engineer of the Syracuse Street Railway and the Syracuse Consolidated Street Railway, which later became the Syracuse Rapid Transit Company. His next step was a promotion to the assistant general managership of this company, of which he became general manager in 1899. For a short time he was general manager of the Lorain (Ohio) Street Railway but returned in 1901 to become engineer of the Utica & Mohawk Valley Railway. His sphere of usefulness in this and other New York Central properties rapidly extended until finally he became vice-president and general manager of all the lines centering in Syracuse and Utica.

Again in 1912 Mr. Allen determined to get into business and organized the firm of Allen & Peck, Inc., which purchases and manages public utility properties.

Mr. Allen was the first president of the American Electric Railway Transportation & Traffic Association, and he was also in 1904 president of the Street Railway Association of the State of New York. Presidencies are, therefore, not new to him. He comes to his enlarged responsibilities with the members of the Association behind him as a unit. He will put "ginger" and snap into the work without arousing antagonism in the large and diversified membership of the association.

ENTERTAINMENT COMMITTEE

Under the direction of Charles R. Ellicott, who very gracefully acknowledged the efforts of W. G. Kaylor, chairman of the entertainment committee, and the other members, the week's events were put through without a hitch. Many of the features introduced were new and tastes of all kinds were catered to. The thorough enjoyment of everyone was shown by the attendance at the various affairs, and the enthusiasm with which the dancing teams, music and other attractions were received. All the members of the committee worked hard to insure this success under the various sub-chairmen, and in conventions to come it will be a hard task to improve or better the arrangements that went through with such snap and enjoyment.

WINNERS AT AUCTION BRIDGE

The ladies' auction bridge tournament which began on Tuesday was completed with the play-off on Wednesday afternoon, the semi-final rounds eliminating all but the following four contestants: Mrs. S. M. Gallaher, Mrs. W. P. Goff, Mrs. Harry B. Logan and Mrs. Edward P. Wisch. In the final round between these four ladies Mrs. Gallaher and Mrs. Goff were paired and succeeded in winning the prizes that had been provided for first place. Mrs. Logan and Mrs. Wisch, as runners up in the tournament, received the prizes accorded for that place.

THE ANNUAL BALL

The annual ball, held last night, was equal in attractiveness and attendance to any ever conducted under the auspices of the association. It formed a fitting climax for the splendid week of entertainment with which the delegates have been regaled during their stay in Atlantic City. The music commenced shortly after nine o'clock, and from then until after midnight the floor was crowded with dancers while many looked on from the sides of the hall. A feature of the evening was the entrance to the floor of Miss Collins and Mr. Little, who delighted the audience with several specialty dances. Mr. and Mrs. S. S. Crane, of Altoona, Pa., also gave a performance of modern dancing which brought forth a lot of applause.

WINNERS AT SKEE-BALL

One of the most interesting of the events scheduled by the committee was the skee-ball tournament, and the large number of players together with the high scores show the popularity of this game. The winner of the grand prize for the ladies is Mrs. T. W. Connette, 240; the second prize being awarded to Mrs. R. R. Paradies, 230. The first gentlemen's grand prize was won by C. G. Chamberlain, 310. The second went to S. C. Morrell, 430, this score being for three games necessary to settle the tie for second place. Altogether 7623 games were rolled in the 325 hours during which the alleys were open. Thursday's daily prize for the ladies went to Mrs. R. R. Paradies, and for the gentlemen to C. G. Chamberlain.

T. F. McKenna, chairman of the committee on skee-ball, together with William J. Fleming, Jr., and H. H. Helms, were constantly at the alleys and had their hands full in taking care of the crowd.

LOST AND FOUND COLUMN

Lost—Manufacturers' Association Badge No. 4419 has been lost. Finder will please return to H. G. McConnaughy at the office, Convention pier.

Lost—Badge No. 5346.

Found—Badge No. 3801.

Found—Gold Seal Fob.

Lost—Mrs. H. G. McConnaughy, while attending the carnival festivities Wednesday evening, lost a small crescent of pearls. A suitable reward is offered for the return of this crescent to the office of the secretary of the Manufacturers' Association.

Lost—A. W. Hulme, general foreman New York Railways, Fiftieth Street and Sixth Avenue, New York, announces the loss of his badge, No. 1027. Mr. Hulme will be very grateful if the finder will kindly mail his badge to the address given.

OBSTACLE GOLF

A large number took advantage of the most interesting course laid out by Gimbel Brothers on the Marlborough-Blenheim lawn and, while the final day's play was held on a damp and difficult green, the following scores attest to the cleverness and ability displayed by the contestants. By those who have gone over the nine holes and have encountered the many obstacles put in their way to make the play difficult, the scores turned in can be appreciated.

The ladies winning the first and second prizes are as follows: Mrs. F. E. Donohoe, with a score of 78 for eighteen holes, and Mrs. L. H. Wilson with a score of 88.

The gentlemen's first and second prizes were won by E. A. MacNutt, with a score of 73 for eighteen holes, and W. F. Ham with a score of 74. Thanks are due to N. M. Garland, chairman of the golf committee, and his associate, H. A. Hegeman, for the manner in which they handled this game, as a great deal of interest was aroused in many who had never had any golfing experience.

TRAP SHOOTING

The trap shooting, which was introduced for the first time this year, proved a popular diversion, and many took advantage of the opportunity to try their skill in handling a gun. The winner of the contest among railway delegates was William H. Hitchcock, who broke 87 birds in 100 shots. The Manufacturers' Association contest was won by Harry Lee, who broke 96 birds in 100 shots. The winning novice was H. MacNutt, with a score in 50 shots of 36. The total number of clay pigeons was 5500 and the number of contestants was 76. The committee having the trap shoot in charge consisted of C. C. Castle, chairman; C. W. Laskay, W. H. Turbee, P. M. Kling, Waldo E. Berry and John M. High.

MANUFACTURERS ELECT OFFICERS

Yesterday at noon the executive committee of the American Electric Railway Manufacturers' Association elected the following officers for the 1915 term:

President: Edwin H. Baker, second vice-president Galena Signal Oil Company, New York.

Vice-President in Charge of Relations with the Parent Association: Charles C. Pierce, manager Railway department General Electric Company, Boston.

Vice-President in Charge of Entertainment: Thomas Finigan, vice-president Pierson, Roeding & Company, San Francisco.

Vice-President in Charge of Finance: F. A. Elmquist, railway representative Sherwin-Williams Company, New York.

Vice-president in charge of Exhibits: D. W. Smith, president The Peter Smith Heater Company, Detroit.

Secretary-Treasurer: H. G. McConnaughy, manager Dearborn Chemical Company, New York.

OTHER CONVENTIONALITIES

Gentlemen! The Chinese-American delegation: Messrs. Ong, Ching and Chur.

Simple declaratives from the delegates' list: Edward Leeds, Henry Baetz, Henry Burns and so does J. M., James Drew, Henry Dates, Byron Fowles (baseball term), Exum Haas, I. May, F. T. Wood.

Farley G. Clark, chief engineer, Toronto Railway Company, arrived with George E. Austin yesterday morning. They are stopping at the Brighton. George says that the Brighton is on Clark's treat, simply to remind the bunch where to find them.

The Chicago Surface Lines party includes J. F. Henning, superintendent of materials and supplies, and E. W. Anger, in charge of carhouses. These two gentlemen have the welfare of 3500 street cars and more than 2,000,000 people at heart. Note the order of preference.

Dean Treat has a new title. Not everybody on the Chicago Special knew it, but just a bit ago he was told to sign assistant general manager Wisconsin Public Service Company, instead of assistant general superintendent., C. R. Phoenecie, formerly general superintendent, being the general manager of that property. Now that the good news is out, are you going to treat, Dean?

ELBERT HUBBARD ON 3-CENT FARES

In summing up his article in the *Fra* on 3-cent fares, Elbert Hubbard said in part:

"We cannot fool calves by giving them whitewash instead of milk. Any business that is depressed, suppressed and submerged until it is hanging on by its eyebrows spreads a depressing effect on the entire community. Run-down equipment, unpainted cars, shabby interiors, flat wheels, what the railroad men call 'Harry Thaws'—that is, loose nuts—these things all react to the disadvantage of every business man in town. Cheap men, cheap equipment and cheap service all tend to put a town to the bad. A street railway system has got to be kept right up to date. The whole thing should be smart, and have a look of prosperity and well-being if the town is going to prosper and go ahead. Visitors judge a town, first by its lights, or absence of them, next by its transportation facilities.

"A 3-cent fare has only one genuine, positive use—and that is to nurse along a political boomlet. Greece started on her downfall when she began to give the voters something for nothing. A pension was devised for every citizen, under the specious argument that a man must be paid for jury duty and was liable to be called upon at any time. This of course was very pleasing, but it pauperized the citizens, evolving a race of Weary Willies. Rome did the same thing over again with free shows, spectacles, pageants, and finally with free bread.

"The voter who is caught by the cheap slogan of free bread, free trade, free rides, free entertainment, or 3-cent fares, is not wise in his day and generation, and the best of it all is the fact that voters everywhere are now becoming alive to the truth of this dictum—something for nothing leaves nothing."

FINAL SESSION OF THE TRANSPORTATION & TRAFFIC ASSOCIATION

Acting President Brush called the Thursday morning session of the Transportation & Traffic Association to order at 9:30 o'clock. The first order of business was the subject of continuing the joint committee of accounts with the Accountants' Association. On motion it was determined to make this joint committee a standing committee.

The report of the committee on standards for car loading was then taken up but not acted upon inasmuch as this report is to be handed to the executive committee of the American Association to be studied by that committee between now and the midyear meeting. The chair stated, however, that any member who was vitally interested could see the records now by getting into touch with the secretary of the American Association.

Training of Employees

The next order of business was the report of the committee on training of transportation employees. In the absence of the chairman, J. T. Crabbs, Brooklyn, the report was read by E. E. Strong, Rochester. The opening discussion related principally to how far it was advisable for the motorman to acquire practical mechanical knowledge of the apparatus in his care. Mr. Strong said some of his men had gone so far as to buy special text-books, and he presumed that they did this with the idea of ultimate promotion. W. J. Harvie said it was all right to answer any questions that a man might ask, but he did not believe in the tendency to make a practical man out of a platform employee.

C. H. Coe, Public Service Railway, stated that his company had obtained wonderful results from a follow-up system which it had inaugurated about fifteen months ago. After a man leaves the instruction classes for platform duty he is followed up for three continuous weeks. During the day the chief motorman makes one or two trips with this man and points out his weaknesses. This practice had reduced the accidents of first-year men to an appreciable extent.

H. C. Moser, Fifth Avenue Coach Company, New York, said that many inspectors and starters had little or no knowledge about time-table principles; also that they tended to spend an undue part of their time with the motorman and not enough with the conductor.

G. W. Manning, Salt Lake City, spoke of the "safety first" movement which had been started among his company's employees before being brought before the public. This company had received about 350 suggestions from the men and most of these had considerable merit.

W. F. Dement, Washington Railway & Electric Company, contributed written discussion on the "safety first" movement and other matters relating to transportation. His company had been giving talks to trainmen assisted by means of lantern slides, moving pictures and bulletin notices. Between March 3 and March 24 fifteen meetings were held at the several carhouses and these were attended by 812 out of 835 trainmen. The main effort was directed toward preventing all kinds of collisions between cars. The result is shown by the fact that from Jan. 1 to Sept. 30, 1914, only seventy-five such accidents occurred compared with 107 for the same period of the preceding year. He heartily approved the committee's recommendation to keep separate the temporary from the permanent bulletins so that the former could be readily destroyed when obsolete. The plan to print bulletins to conform in size with the pages of the rule book, for individual issue, did not seem practicable. He recommended, however, that one or more rule books be kept up to date by some loose-leaf binding and manifolding process. These might be termed "Master Rule Books," and when the time arrived for reissuing the rule book it would only be necessary to send the master book to the printer.

As to wages his company had paid the men daily since 1901. Payment is made by the depot clerk (receiver) except in a few cases where crews finish their day's work some distance from the carhouse, in which case the conductor is permitted to pay his motorman. The conductor enters on his day card the conductor's pay and the motorman's pay. These figures are checked by the depot clerk by means of his "on and off" sheet. The amount of pay and the name of each conductor and motorman is entered by the depot clerk, on a train register or payroll, which is forwarded to the treasurer's office for final checking.

Referring to instructions of employees Mr. Dement wrote that his company had started with an 18-ft. skeleton car carrying hand brakes, G.E.-800 motors and connections for both overhead and conduit operation. This car was located in the instruction room and was jacked up so that the motors could be operated. The company now uses a larger skeleton car with four motors and air brakes. This car is stored at the station where the school is located, and one day of each week all student motormen are taken on it to a piece of idle track about ½ mile long, over which instructions in the operation of cars and location of car trouble are given.

J. E. Duffy, Syracuse, said it was not expected on his property that the younger men could absorb all the bulletins that had been issued during the past five years. The company had established a rule that the new men shall be under the direction of the chief instructor instead of the general superintendent for six months so far as minor discipline was concerned. Good men were scarce and every opportunity should be taken by the railway to give a chance to the man who shows his willingness to do the right thing. It was his experience that bulletin boards were not read as they should be. It has been the practice of his company for the past five years to collect all permanent bulletins every year or two for printing in a book, which is of the size of the rule book, for distribution among the men.

C. E. Learned, Boston, discussed the safety movement in its relation to the employee. There was often a feeling among the men that the accident work was simply a selfish movement on the part of the company. Nevertheless his company had undertaken to interest the employee and believed it was succeeding. The question of intoxication had been taken up with the union officials and discussed so sensibly and amicably that the men on the road now considered the use of liquor a sufficient cause for discharge. He did not think that the men were as interested in short hours as in a good pay envelope. As to bulletin boards all important rules were not only posted on the board but were put on gum stickers so that the men could place them in their rule books. Consequently the men carry the rules all the time, and if they do not understand them can talk them over with their superintendent.

J. R. Ong, Wisconsin Railroad Commission, pointed out the importance of practical "safety first" by eliminating dangerous car conditions, such as non-tripping fenders. It was often found that the fender was deliberately placed so high that it could not be tripped if it passed over a prone body on the track. The topographical conditions were, of course, sometimes beyond the company's control, but in other instances the fenders were carried high simply on account of poor track. If the companies were sincere in the "safety first" movement they should also place the proper fending devices on interurban cars.

J. V. Sullivan, Chicago, said that the street car accidents in Chicago for 1913 have shown a decrease as compared with 1912, in spite of an increase in the number of cars operated and passengers carried. One of the best features of the Chicago work was the series of motion picture talks in the public schools and parks.

W. F. Ham, Washington, stated that the bulletin board demanded from the men more than could be reasonably expected from the higher officials of the company. He has suggested to his transportation department that a rule book be issued twice a year. Even the division superintendents, all intelligent men, do not always know what the rules are. When bulletins are posted frequently it is very essential that the men have some way of getting them in compact form. Furthermore when men are transferred they should have before them data of the special conditions on the new division. Referring to Mr. Dement's remarks he said that the reason for paying the men daily was almost entirely because of the fact that his company believed it would have a better effect on the men. A conductor who was getting his daily wage was less inclined to get hard up and be tempted to take that which was not his. There had been no difficulty or very little extra accounting in changing from the flat daily wage to the graduated daily wage. This system has been in use for three years.

Mr. Ham also described the profit-sharing plan whereby 26 per cent of the passenger earnings are set aside as a special fund. From this are deducted first the wages paid to the trainmen, and second the amount actually disbursed for the settlement of accidents. The remainder was distributed among the men at the end of the year. In this way the men benefited directly by reducing accidents. His company is now working on a plan whereby the men on each division will be informed of the cost of each accident and its nature. He was hopeful that when the men knew the number and cost of the accidents on each division they will become still more interested in reducing them. Upon motion the report of the committee was approved.

RESOLUTIONS OFFERED

Vice-Chairman Nicholl then took the chair following which W. H. Collins presented the report of the committee on resolutions.

Three sets of resolutions had been prepared by Charles Hewitt, chairman; W. H. Collins and C. Loomis Allen, members of the committee. The first set of resolutions expressed regret at the resignation of D. A. Hegarty as president of the association due to his entering other business, and presented the hearty thanks of the association to Mr. Hegarty for his splendid work as a committeeman and officer; the second was a resolution of thanks to Acting President M. C. Brush and the other officers and members of the various committees for their work of the year; the third was a resolution of thanks to the Manufacturers' Association for the splendid exhibit.

CLOSING BUSINESS

The report of the committee on nominations, consisting of Messrs. Shannahan, Donecker and Sullivan was then presented as follow: President, M. C. Brush, second vice-president Boston Elevated Railway; first vice-president, H. A. Nicholl, general manager Union Traction Company of Indiana; second vice-president, L. C. Bradley, assistant district manager Stone & Webster, Texas district; third vice-president, R. E. Danforth, general manager Public Service Railway. For executive committee: J. K. Choate, vice-president, J. G. White Management Corporation; T. C. Cherry, general manager Maryland Electric Railways; George H. Harris, general superintendent San Francisco-Oakland Terminal Railways; C. D. Emmons, general manager Chicago, South Bend & Northern Indiana Traction.

The secretary was duly instructed by the chair to cast one vote for the entire ticket, and all the officers and members of the executive committee were then declared elected.

After Mr. Brush had been inducted he called attention to the necessity of doing extra good work during the coming year, as doubtless a great many delegates who had come regularly to Atlantic City would be unable to go to San Francisco. He then thanked the association for his election as president. The meeting was then adjourned.

FINAL SESSION OF ACCOUNTANTS' ASSOCIATION

The first order of business for the Accountants' Association yesterday was the consideration of the report of the special committee on changes in committee organization, appointed last Tuesday. The committee recommended standing committees and their respective memberships as follows: Classification of accounts, 5; passenger accounting, 5; express and freight accounting, 5; education, 5; accounting definitions, 5; representing association at convention of National Association of Railway Commissioners, 3; joint committee on engineering accounting, 5; joint committee on transportation accounting, 5; and joint committee on claims accounting, 3.

It was also recommended, that, with the exception of the classification committee, the majority of each of the above committees should hold over from one year to the next in order to secure continuity of work. The classification committee should remain as at present constituted. In case of the resignation of any member of a standing committee, his successor should be appointed by the president. Special committees should be appointed from time to time when necessary, to be discharged upon the completion and acceptance of their reports. It was moved by H. B. Cavanaugh, Cleveland, Southwestern & Columbus Railway, Columbus, Ohio, seconded by W. F. Ham, Washington Railway & Electric Company, Washington, D. C., and duly carried, that the report be adopted.

President Glover announced that owing to the unsettled state of the accounting features of valuation, A. T. Smith, division of valuation, Interstate Commerce Commission, was unable to attend as scheduled, but that Director C. A. Prouty promised to arrange for an address by some member of the valuation staff next year.

Robert Seeley, The North American Company, New York, then gave his address on "The Accounting Treatment of Depreciation," which President Glover declared to be the most valuable contribution to the association in recent years. Secretary M. W. Boylan read communications from H. J. Davies, Cleveland (Ohio) Railway, and W. H. Forse, Jr., Union Traction Company of Indiana, Anderson, Ind. Mr. Davies mentioned the provisions of the Cleveland franchise regarding the treatment of maintenance, renewals and depreciation. He felt that the reserve for these purposes would better be based on car-miles or probable life. In connection with the latter basis he explained the inventory being made in Cleveland, which would probably give the average mortality of the various property items. Mr. Davies agreed with Mr. Seeley, that original cost accounts should not be disturbed until the retirement of property.

While in accord with the general principles of Mr. Seeley's article, Mr. Forse noted that the company's surplus might be sufficient to care for so-called depreciation even if the balance sheet contained no specific reserve, and also that the new Interstate Commerce Commission classification makes the accruing of depreciation mandatory upon interstate carriers. Mr. Forse was opposed to any sweeping assertion that no charge should be made against the depreciation reserve for expenditures in the way of renewals.

M. S. Moyer, Barclay, Parsons & Klapp Company, asked Mr. Seeley if the New York Public Service Commission classification had not sufficiently distinguished between maintenance and depreciation. Mr. Seeley replied that the New York practice, if carried out, was ideal, but that the commissions had started in the middle of things and had difficulty in dealing with property in service for some time. In reply to an interrogation from P. L. King, San Antonio (Tex.) Traction Company, Mr. Seeley said that a gradual replacement of a car part by part was a good illustration of the reason why the maintenance and depreciation charges should be combined. The difference between the maintenance expenses and the estimated amount for both charges should be carried to the depreciation reserve.

Mr. Ham believed that the use of the term "insurance replacement" suggested by Mr. Seeley would clear up much of the confusion surrounding the subject of depreciation. Mr. Ham mentioned the various component parts of so-called depreciation to show the indefiniteness of the items concerned and to prove that a depreciation fund could be only an approximation of the actual physical loss. He expressed himself as thoroughly disgusted with those who endeavored to secure minute details on this subject. Mr. Seeley leaned toward providing for depreciation by means of a reserve account accrued periodically over a period of years, but Mr. Ham, citing the supposititious case of the possible abandonment of the New York elevated system on account of public demand, said that the public to-day should not be required to bear the burden of such ultimate retirement of property and no charges therefor should be included in the present rate. In such a case the value of the property should be continued in a suspense account to be amortized in future years. A motion of thanks to Mr. Seeley for his paper was then duly carried.

President Glover expressed his appreciation for the large size of the meetings this year and also for the presence of several new members. He then called upon the committee on resolutions, which presented resolutions of thanks to the several speakers and committees at the convention as well as to the Manufacturers' Association. R. N. Wallis, Fitchburg & Leominster Street Railway, Fitchburg, Mass., then presented the recommendations of the committee on nominations, as follows: President, C. S. Mitchell, Pittsburgh (Pa.) Railways; first vice-president, T. P. Kilfoyle, Cleveland (Ohio) Railway; second vice-president, F. J. Pryor, American Railways, Philadelphia, Pa.; third vice-president, H. A. Culloden, Pacific Electric Railway, Los Angeles, Cal., and secretary and treasurer, M. R. Boylan, Public Service Railway, Newark, N. J.

The following members were nominated for the executive committee: L. T. Hixon, Terre Haute, Indianapolis & Eastern Traction Company, Indianapolis, Ind.; J. C. Collins, New York State Railways, Rochester, N. Y.; W. C. Nicholson, Omaha & Council Bluffs Street Railway, Omaha, Neb. and F. E. Webster, Massachusetts Northeastern Street Railway, Haverhill, Mass. H. L. Wilson, Boston (Mass.) Elevated Railway, moved the casting of a unanimous ballot by the secretary for the above nominees under a suspension of rules, which motion was duly seconded and carried. Mr. Mitchell thereupon took the chair and called upon the newly elected officers and committeemen for a few words, after which the session was adjourned.

THURSDAY SESSION OF ENGINEERING ASSOCIATION

The Thursday morning session of the Engineering Association was called to order by President Hanna at 11:45 following the joint session with the Accountants' Association.

The order of business was the report of the committee on power generation, which was presented by B. F. Woods and J. W. Welsh. An abstract of this report is printed elsewhere. Preceding the discussion L. P. Crecelius also presented the report of the committee on smoke abatements.

Smoke Abatement

The report stated that public sentiment was crystallizing against dense black smoke emissions from the chimneys of power plants in cities of more than say 20,000 inhabitants. Due partly to the general belief that smoke indicated excessive fuel loss and that its elimination would result in enormous economy, the committee was led to include a digest of the studies made by the Bureau of Mines. Thus, in March of this year Samuel B. Flagg, engineer Bureau of Mines, had presented a paper on the "Combustion of Coal and Smoke Abatement" before the Cleveland Engineering Society, in which he pointed out that the presence or absence of smoke at the top of any stack was not of itself a proof that the plant was inefficiently or efficiently run or even improperly or properly operated. Continuing, he had said that the difficulty of obtaining the intimate mixture of air and combustible gases before they come in contact with the surfaces which the lower temperature below the efficient points was the greatest to overcome, and that there is great need for the proper furnace construction to bring about this mixture. A great many ways had been tried to overcome the trouble. In numerous cases the use of better mixing devices made it possible to obtain complete combustion and prevent smoke without the admission of any more air. Other methods were the decrease of the rate of heating of the fuel so as to make it gradual and more nearly uniform.

Continuing, the committee said that it was important to examine the best practice in regard to furnace construction and operation in connection with the possible smokeless combustion. It was as yet practically impossible to define clearly and definitely the quantity or degree of smoke for the various grades of coal under conditions which are economically sound when viewed from every standpoint. The problem depended also on the character of the community. In a non-industrial community it might be possible to go to the expense of lowering the rate of the furnaces below the point of maximum usefulness or of substituting a fuel containing little or no smoke producing volatiles; but in the case of an industrial center such measures would do great economic injury. Furthermore, as the present methods of measuring smoke density were very indefinite and unsatisfactory and the work of the committee could well be continued toward studying improvements in this line. The report also contained a number of illustrations and explanations showing several designs of furnace and boiler settings recently installed to lessen the degree of smoke emission as governed by the following requirements.

Case 1. Low investment of prime importance to the exclusion of all other considerations.

Case 2. The use of low-grade coals, viz., high smoke producing volatile content and high ash content.

Case 3. High capacity and economy where the cost and character of the fuel supply justifies it.

Power Generation

In opening the discussion William Roberts, Akron, said that he did not believe it was possible to operate any system of overfeed stokers as efficiently as underfeed stokers, although there were occasions when certain types of stokers had to be used on account of the fuel. He had one station where nine overfeed stokers of three different types caused more repair expense than the sixteen underfed stokers of one type in another station. As to smoke he did not think it was possible under any circumstances with conditions of varying load to eliminate the appearance of an excessive amount of smoke.

J. W. Welsh, Pittsburgh, reported that he had gone into many boiler rooms where the men said they were operating under high efficiency yet large holes would be discovered in the fires despite their denials. This was the condition that led to the inefficiency of the overfeed stoker. He believed that if it was operated with skill it would develop almost the same efficiency as the others.

Charles H. Bigelow, Millville Traction Company, found that one bad point of the overfeed stoker was the sifting of coal under certain conditions. This condition did not occur with the underfeed stoker which had also eliminated smoke from the chimney.

In reply to a question Mr. Woods said that CO_2 recorders were applicable to both types but especially the overfeed. Most of the trouble with recorders was that most of them lagged ten to thirty minutes behind the procession. Information as old as that was of small value to the fireman. However, these instruments were being steadily improved.

Mr. Alpern, American Engineering Company, stated that one important condition in the operation of stokers was the poor boiler setting. His company had often taken gas notes at the top of the first or second pass and usually found there was quite a dilution of gas between that pass and the flue. The tendency to go to steel setting was a splendid thing as it would cut down radiation losses and dilution materially. The condition of the boiler baffler also had a material bearing on capacity.

B. F. Wood said the idea of overload capacity should be dissipated in some way. There really was no overload on the boiler. It was operated simply at some increase over what had been the manufacturer's customary rating. He knew of a case where the boilers were operated for several hours at several hundred per cent above the manufacturer's rating. This was with oil-fired furnaces, but indicated that the boiler would have been able to take care of the same duty if coal-fired furnaces had been developed to the higher rate. We had not reached a boiler rating limit, but rather a furnace limit.

In reply to a question by Mr. Roberts about putting reactance on the grounded neutral of a 22,000-volt transmission line (in view of the fact that a possibility of disruption might throw 22,000 volts on to a 13,200-volt lead), Mr. Welsh said there was no doubt that the use of resistance or reactance in the grounded neutral of a transmission line would greatly reduce the short-circuit current.

Appendix C, relating to sixty cycle and twenty-five cycle rotary converters was then considered. Mr. Crecelius pointed out that the data, especially as to cost and efficiency, were about two years old, so there might be some variation in securing figures to-day on individual cases.

Mr. Roberts said that in his experience the sixty-cycle rotary required at least twice as much attention as a twenty-five-cycle machine. He has only one man to look after eleven twenty-five-cycle machines whereas three men are required for fifteen sixty-cycle rotaries. His company had purchased sixty-cycle rotaries because the lighting and power load had increased so much faster than the railway load, the ratio being 123 to 25.

Upon motion the meeting was then adjourned.

FINAL SESSION OF THE AMERICAN ASSOCIATION

President Black called the final session of the American Association to order at 2 o'clock yesterday afternoon. The first business was the presentation of the report of the committee on compensation for carrying United States mail. This was read by Mr. Brush and is published elsewhere in this issue.

The report of the committee on federal relations then followed. This was read by Chairman Brady and is also published in another column.

In the discussion on this report General Harries described the hearing in connection with the Crosser bill in Washington last spring. It is said that it was almost an accident that the association became actively concerned. He spoke of the gentleman who assisted, including Mr. McCarter, Mr. Clark, Mr. Rosecrants, Mr. Nicholas, Mr. Kerr, Mr. Henderschott and others. The arguments presented were potent, and anyone who will read the testimony presented before the committee will have difficulty in understanding how the majority of the committee could have voted in favor of the bill. General Harries also referred to the good work done by the mail committee and said that the contest was now largely up to the members of the association to work individually. They should discuss the matter with the congressmen in their districts and show them the correctness of the position of the railway companies. It was impossible to do all of the work by frontal attacks at Washington. The campaign should include a rear attack, directed at the individual congressmen in their home districts.

The reports of the commitee on costs of passenger transportation was then read. It is published in another column. After the reading of this report President Black urged upon all member companies the importance of sending to the Bureau of Fare Research their operating statistics. This bureau can be made very valuable to the companies, he said, if it receives their co-operation in the way of furnishing data.

Mr. Stearns then presented his paper on "A Zone System of Fares in Practice." It described the system of fares in use in Milwaukee, gave the history of the plan and presented data on the results of the operation of the zone system in European cities. It was illustrated by a number of charts and a map. Owing to the time required to make the engravings from this illustrative material the publication of this paper in this journal will have to be postponed until after convention week.

In the discussion which followed the reading of this paper W. J. Clark complimented the author upon the results of his investigations. Upon motion of Mr. Henry it was voted to print the article in pamphlet form for distribution among the members.

The report of the committee on taxation was then read. It will appear in the issue of Oct. 17. Upon motion of Mr. Brady a vote of thanks was extended to Mr. Tingley for this report. The association also voted to print and distribute among the members the report of the committee on transportation of United States mail.

The secretary then read a letter from A. B. Guigon, chairman of the committee on a legal association. The letter simply reported progress.

The report of the committee on the 1915 convention was then read. It is published elsewhere in this issue. In further explanation President Black urged on all member companies the importance of replying to the bulletins sent out by the secretary as soon as possible. He said that the people in San Francisco expected fully as large attendance under the existing conditions as they had hoped for before the European war was declared. They believe that the travelers who usually go abroad, numbering several hundred thousand annually, will in large measure visit California during the coming year. He felt sure that the journey to the Pacific Coast would repay everyone who took it. In conclusion he said that the exposition was one of the most beautiful and interesting the world had ever seen. The fair would be opened on time, namely Feb. 20.

The committee on nominations then reported as follows:

For president: C. Loomis Allen, president Newport News & Hampton Railway, Gas & Electric Company, Syracuse, N. Y.

For first vice-president: Charles L. Henry, president, Indianapolis & Cincinnati Traction Company, Indianapolis, Ind.

For second vice-president: John A. Beeler, vice-president and general manager Denver Tramway Company, Denver, Col.

For third vice-president: L. S. Storrs, president Connecticut Company, New Haven, Conn.

For fourth vice-president: Timothy S. Williams, president Brooklyn Rapid Transit Company, Brooklyn, N. Y.

These nominations were received with applause. Upon motion the secretary cast one ballot for these officers. President Black then appointed Mr. Brady and General Harries a committee to escort the newly elected president to the chair, and added that he bespoke the same hearty cooperation for Mr. Allen, the new president, as had been accorded him during the past year.

President Allen thanked the association for his election and promised to carry forward the work of the association to the best of his ability. He then called for the report of the committee on resolutions. This was presented by Mr. Henry.

Mr. Henry gave a list of the members of the association who had died during the year and expressed its appreciation of their services and sorrow at their departure. The thanks of the association were also expressed to the retiring officers, to the Manufacturers' Association, to the technical press and to the family of the late Anthony N. Brady for gifts or services rendered.

The meeting then adjourned.

CLOSING SESSIONS OF THE CLAIMS ASSOCIATION

After the joint session of the Claims Association and the Accountants' Association on Wednesday, the former association received the report of the committee on claims accounting, which was read by Mr. Bennett in the absence of Chairman Davies. Following this report Mr. Drown led the discussion and also made suggestions regarding a proper classification. The report was recommitted to the committee with instructions to circulate it among the member companies, asking for an expression of opinion from the accountants and claim agents relative to the classification of accounts desired. These will be used in formulating an account classification which may be reported at the next convention.

The Thursday morning session of the Claims Association followed the regular program. Under the subject of general business Mr. Walsh called the association's attention to the death of his company's president, Captain McCulloch. Following this the report of the nominating committee was received, and the following officers were elected for the ensuing year: President, William Tichenor, claim agent Terre Haute, Indianapolis & Eastern Traction Company; first vice-president, George Carson, claim agent Puget Sound Traction, Light & Power Company, Seattle, Wash.; second vice-president, R. E. MacDougal, claim agent New York State Railways, Rochester, N. Y.; third vice-president, S. B. Hare, claim agent Altoona & Logan Valley Traction Company; secretary and treasurer, B. B. Davis, claim adjuster Columbus Railway & Light Company. This will be Mr. Davis' tenth consecutive term in office.

The executive committee includes P. C. Nickel, claim agent New York Railways; F. J. Whitehead, manager claims department Washington Railway & Electric Company, Washington, D. C.; C. B. Proctor, claim agent Memphis Street Railway, Memphis, Tenn. The subjects committee is composed of F. D. Edmonds, assistant general attorney New York Railways; H. D. Briggs, assistant general claim agent Public Service Railway; C. B. Brunner, claim agent Easton Transit Company, Easton, Pa., and J. E. Burr, claim agent Eastern Pennsylvania Railways, Pottsville, Pa. The members of the ways and means committee include J. S. Harrison, Jacksonville, (Fla.) Traction; J. S. Kubu, claim agent New York State Railways, Utica, and A. Dixon, El Paso, (Tex.) Electric Railway. The members of the employment committee are B. B. Davis, Columbus Railway & Light Company; E. E. Slick, Union Traction Company of Indiana, Anderson, Ind., and C. J. McAleer, Schenectady Railway.

Before adjourning its final session a vote of thanks was extended to all those who had contributed papers, and H. K. Bennett presented Mr. Weh with a gold badge of the association as a token of respect. Upon motion, Mr. Weh by reason of his being a past president, was made a member of the executive committee.

The following statement is attributed to a car driver of Burnley, England, who has been serving at the front in the King's Own Lancaster Regiment, and who has been invalided home: "The French treated the English Tommies like gods. If we had been King of England they could not have done more for us. I was never in a grander country."

JOINT MEETING OF THE ENGINEERING AND ACCOUNTANTS' ASSOCIATIONS

President Hanna of the Engineering Association called the joint Engineering and Accounting meeting to order yesterday morning at 10 o'clock, with President Glover on the platform for the Accountants' Association. The report of the committee on engineering accounting was presented by its chairman, J. P. Barnes, Syracuse & Suburban Railroad, Syracuse, N. Y. This report, abstracted elsewhere in this issue, covered the three subjects of overhead charges, inter-departmental charges and cost accounting, each of which the delegates discussed in turn.

OVERHEAD CHARGES

This section of the report was not extended, owing to the report of the committee on overhead charges of the Accountants' Association presented Wednesday. President Glover summed up the joint committee's report on this subject by stating that it called attention to the fact that some proper items of overhead charges were often left out of construction cost. In a number of cases construction work was shown on the books at a certain amount and on subsequent analysis it was found impossible to construct that piece of work for this amount. In President Glover's opinion, this was largely caused by a misunderstanding of the rulings of commissions. In this connection he cited the new ruling of the Interstate Commerce Commission specifically providing for charging to construction work the proper amounts of salaries of officers when engaged thereon, and he emphasized the desirability of following this ruling closely.

INTER-DEPARTMENTAL CHARGES

In supplementing the committee report on inter-departmental charges, Mr. Barnes said that when a job was done for construction or operation, there was accrued an unavoidable overhead cost composed of two increments, one including operating items such as cost of supervision, administration, office expenses, etc., and the other including fixed items like interest, taxes, etc. In the case of construction work the overhead cost was as large a part of the cost as the actual cost of materials and labor and should be represented in the property accounts. As regards inter-departmental operating charges, however, the same elements of overhead cost arose, but operating accounts did not make any provision for, and actually did not contain the second increment of fixed charges. Mr. Barnes said that if inter-departmental operating charges were to be handled at all they must be handled under the present system differently from the construction inter-departmental charges, and the question was whether such treatment was good accounting and good engineering.

In reply to a question by Terrance Scullin, Cleveland (Ohio) Railway, President Hanna said that most public service commissions were liable to depend for information on outside sources, and that one of the principal problems now before the parent association was to gather information so that the member companies might be in a position to guide the commissions and to put before them information on this subject, properly prepared. In addition, President Glover stated that the proposed system of inter-departmental charges was a system of accounts entirely separate and distinct from the regular operating charges. The cost statement was a statement entirely separate from the operating or income statement prescribed by law and one that would show the true state of affairs of the company better than would the latter statement, although balancing with it as to the total.

C. H. Lahr, Northern Ohio Traction & Light Company, Akron, Ohio, believed in the theory of the report, but doubted its good practical effects. H. G. Salisbury, Toronto (Ont.) Railway, thought that the only solution was to use a percentage basis to cover the overhead charges, according to the amount of work produced, for both labor and material. William Roberts, Northern Ohio Traction & Light Company, Akron, Ohio, asked why there should be any difficulty in distributing overhead charges, when manufacturers could apportion such charges with sufficient correctness to be able to make estimates of the cost of repairs or manufacture plus such charges.

G. W. Palmer, Jr., Bay State Street Railway, Boston, Mass., criticised the loading of estimates with an increment for overhead expenses so as to show a total in excess of outside prices, when the work did not result in any increase in the total overhead. In reply J. P. Ripley, J. G. White & Company, New York, emphasized the desirability of securing accurate costs, and C. R. Harte, Connecticut Company, New Haven, Conn., said that if the overhead was properly pro-rated it would take care of itself just as it did in a manufacturing plant. When such a plant had too high an overhead for competitive purposes, it got more work and cut down the overhead. The overhead charges had a fluctuating value depending on the output.

Mr. Ripley asked for a discussion from engineers regarding a return on construction equipment engaged in construction work. In reply L. P. Crecelius, Cleveland (Ohio) Railway, outlined the plan followed by his company. In the case of new construction work, estimates were prepared subject to approval by the street railway commission. In these all costs were carefully detailed and analyzed and an arbitrary overhead charge of 15 per cent of the total cost was added, this percentage covering contingencies, interest on money and miscellaneous items.

W. J. Mead, Cleveland (Ohio) Railway, brought out the interesting point that no fast rule could be devised for giving the right percentage of burden or overhead charges. What would be right in one place would be wrong in another. There was no way to get at the facts, except after long years of operation. Martin Schreiber, Public Service Railway, Newark, N. J., said the fact that the inclusion of overhead charges would run the cost up should not work against the proper principle. If it really cost more when all the overhead charges were added the work should certainly be done outside. Often operators seemed put out by the fact that they were not able to make small articles on their own property as cheaply as they could buy them outside, but in this day of specialties this was not a disgrace.

It appeared to H. F. Merker, East St. Louis & Suburban Railway, East St. Louis, Ill., that it was not proper to purchase an article outside if its manufacture inside would reduce the overhead for the department making it, for the company might save something through the department doing its other work with less overhead expense. If the department was crowded, however, and the making of the article would increase the total overhead, it would be better to have the work done outside.

Mr. Schreiber said the committee had tried to agree on a certain percentage for inter-departmental charges, but it was found that every particular case had to be analyzed separately. As regards very small articles, it would not make much difference whether the overhead was charged, if overhead were charged on larger jobs. Theoretically the small piece should have an overhead charge just as much as should fifty cars, but practically it made little difference.

Charles H. Bigelow, Millville (N. J.) Traction Company, was of the opinion that in repair shops where a number of men were carried on account of break-down jobs, the minor articles should not stand the overhead charges, for these should be placed against the break-down accounts. Mr. Harte touched upon the need of consistency in treating overhead charges on small and large articles, so as to be prepared to substantiate appraisal figures before commissions. Mr. Barnes then read two paragraphs in the report of the committee which to his mind summed up the entire discussion.

COST ACCOUNTING

Mr. Barnes next outlined the cost accounting section of the report. G. G. Whitney, Washington Railway & Electric Company, Washington, D. C., said that many of the companies during the past year had realized the value of cost accounting, especially those engaged in valuation work. He recommended the use of a system of work order or job numbers. P. L. King, San Antonio (Tex.) Traction Company, emphasized the importance of co-operation between the engineering and accounting departments in cost accounting work, and in reply to Mr. Merker said that in his company after the work was completed a report of final cost was made up in detail and a copy given to the engineering department for use in forming future estimates. Mr. Bigelow stated that such statements were eminently necessary. President Hanna noted that the provision of the report calling for "a final statement from the accounting department showing the actual cost of the work" covered this point. Mr. Harte said that no charges should be added to the authorization except as they passed through the hands of the engineer or the person responsible for the authorization. In large companies the engineer in charge should have a monthly comparison of the auditor's book statement and the estimate in order to head off charges improperly made.

H. H. George described the practice of the Public Service Railway engineers in furnishing an estimate of the replacement value or original construction value of the work done at the same time the estimate of proposed work was made, and after the work was done in furnishing the auditing department with a revised estimate of the cost of materials actually replaced. At this point Charles H. Clark, Cleveland (Ohio) Railway, and Mr. Roberts raised some questions regarding the accounting treatment of replacements, which were ably answered by Mr. Barnes. Then followed a discussion between Messrs. Barnes, Merker, Glover and Palmer, regarding the non-replacement of as much value as originally estimated. The concensus of opinion finally seemed to be that the first estimate of replacements should be revised to show the value of the articles actually replaced, which should then be written off on the books.

Mr. Barnes then called attention to the fact that it was upon the suggestion of the joint association that the Interstate Commerce Commission system of accounts was revised, which should be a source of great gratification to the members. Mr. Roberts moved that the report of the engineering-accounting committee be adopted and that the committee be continued, which motion, together with a vote of thanks, was carried.

LIFE OF RAILWAY PHYSICAL PROPERTY

Mr. Schreiber then reported for the committee on life of railway physical property, to the effect that this joint committee had during the last year given further study to the subjects outlined and discussed in its 1912 and 1913 reports, that it had followed closely the work of member companies and studies of depreciation and life of physical property by other technical associations and bodies, and that it had in preparation its final report, although recent developments had made the submission of such a report inadvisable at this time. Mr. Ripley moved that the report of progress be accepted and the committee be continued. The motion was carried and the joint meeting then adjourned.

According to the Department of Commerce, the United States leads the nations in the value of manufactures, although the products of its factories are chiefly consumed at home. In 1909 the United States produced more than $2,000,000,000 in manufactures, of which only about 5 per cent was sold to foreign countries.

REPORT OF COMMITTEE ON FEDERAL RELATIONS

The report of the committee on federal relations, presented before the American Association yesterday, mentioned the appointment of Horace F. Clark, of the law firm of Clark, Prentiss & Clark, as Washington representative of the association. Mr. Clark's appointment was made after the annual meeting last year, and followed the appointment of E. B. Burritt, the former Washington representative, to the office of secretary of the association.

The report then gave a review of some of the bills which had been presented before Congress during the past year and the action of the committee thereon. In the early part of 1914, the report says, there were five bills in the House of Representatives compelling the speedy substitution of steel for wooden cars in interstate passenger service. Some were more drastic than others, and it was apparent that electric railways engaged in interstate commerce would be seriously affected by the enactment of any of these bills. Therefore a hearing was arranged in January before a sub-committee of the House committee on interstate and foreign commerce in Washington and was attended by members of the committee on federal relations and other representatives of the electric railway industry. An account of this hearing appears on page 533 of the Electric Railway Journal for March 7, 1914. The House committee on interstate and foreign commerce has not yet reported any of the bills on steel cars pending before it, but an omnibus bill has been prepared to take the place of a number of these bills and was introduced in May by Mr. Stevens, of New Hampshire. Its number is H. R. 16,875. Electric railways are exempted from the operation of this bill by Section 17, which reads that "the provisions of this act shall not apply to electric street railways or electric interurban railways." It is believed that the arguments presented at the hearing favorably impressed the sub-committee and that any bill which it reported relating to steel cars will exclude electric railways from its operation.

The federal relations committee report then described the hearings conducted before the House committee on the District of Columbia in regard to the proposed municipal ownership of the street railways in Washington. The committee adds that it believes that the force of the arguments made in the report of the minority members of the House committee against municipalization will ultimately prevail, but every member company should make a point of seeing that these arguments are brought to the attention of the representative in Congress from its district.

The report then refers to House bill 16,586, amending the interstate commerce act so as to require approval by the commission of stocks, bonds, notes, etc., payable at periods of more than twelve months after date and issued by common carriers subject to the act. The bill was passed by the House, and as passed, it applies to electric railways engaged in interstate commerce. The federal relations committee arranged for a hearing before the Senate committee, and this committee reported the bill to the Senate with a number of important amendments, including one reading as follows:

"The term common carrier railroad corporation, as used in this section, shall not be construed to include street railway lines or electric interurban lines unless they form a part of a railroad system operated in part with steam."

The bill in this form is pending before the Senate, but it is generally understood that no legislation on this subject will at present be urged for passage.

Other Bills and Conclusion

The report referred to other bills of considerable importance to electric railways which have been before Congress this last year. One is to subject urban street railways to the jurisdiction of the Interstate Commerce Commission, and its immediate object appears to give to the commission jurisdiction over the Omaha-Council Bluffs controversy, which, in June, 1913, the Supreme Court of the United States held was beyond the jurisdiction of that body. The subject of compensation to employees of common carriers engaged in interstate commerce is covered by several of the other bills introduced. The Federal Trade Commission act, which became a law in September, probably has little relation to electric railway companies, but the Clayton antitrust act contains several provisions of interest to them. One is the provision against the acquisition by one interstate corporation of the capital of another when the effect is to lessen competition. Another relates to interlocking directorates.

In 1913 the committee on federal relations called attention to the "gradually increasing scope of the relations between the electric railway industry and the United States government." In its present report it says that the record of the past year lends confirmation to this statement. The report concludes as follows:

"It is too early to say that Congress has recognized the impropriety of making all of its legislation in relation to common carriers by railroad applicable to electric railways equally with the trunk line steam railroads. At the same time, it is believed that progress has been made in securing that recognition. The absurdity of requiring, for instance, the comparatively small and weak electric carriers of the country to submit to distant authorities at Washington the issues of notes, stocks, bonds and other obligations already abundantly supervised by state authorities, is apparent as soon as really considered. The fact that important committees of the House and Senate have manifested their realization of the differences between steam and electric railways by making exceptions to bills as above indicated encourages the hope that in future legislation the two classes of railroads will be kept separate. The probability that future federal legislation affecting the electric railway industry will be fair, reasonable and workable would be much enhanced if steam and electric railroads were regarded and treated by United States congressmen and senators as belonging to different classes. Our membership can do much by personal interviews and communications with representatives and senators to have the differences between the two classes of carriers recognized. The subject is so important that no member should fail to do what he can to secure the result aimed at."

WHAT IS "PUNCH"?

What is that force in an advertisement that makes you buy the thing advertised?

What is it that enables one man to sell two or three cars while the other fellow isn't selling any?

We call it "punch" in a general way, but what is "punch"?

Punch is vim vitalized. It is vigor with a voltage behind it. It is "pepper" coupled to "push." It is power, personality, persistency and pugnacity done up in the same package.

It is knowing enough—not too much.

It is talking enough—not too much.

It is the correct sizing up of a situation.

It is knowing what to do with a situation when once sized up.

It is knowing how to say and do forceful things in a forceful way.

It is knowing when to pull the order blank.

It is the ability to get out of a tight place with the order.

It is dominating the interview and coming away with the check.

"Punch" is the child of ambition and the father of success.

"Punch" is just plain, every-day "horse-sense" with a "kick" in it.—*Ford Times.*

REPORT OF COMMITTEE ON TRAINING OF TRANSPORTATION EMPLOYEES

The report of the committee on training of transportation employees of the Transportation & Traffic Association, presented yesterday, stated that data sheets were sent out to the member companies covering the following subjects assigned for investigation: 1. A comprehensive investigation of the "safety first" movement. 2. Bring up to date the digest of state and municipal regulations affecting employment. 3. Recommend practices for handling bulletin boards. 4. Study of the various methods of paying wages. 5. Recommendation regarding the standardizing and use of training schools, instruction cars and apparatus for various sized properties.

The committee decided, on the subject of "safety first," that its general adoption by a large number of companies was too recent to justify definite conclusions. Also, that the results obtained were believed to be too involved with attending influences to justify a definite statement. The committee stated, however, that if interest and enthusiasm could be maintained, further trial of the movement was warranted, but that the results should be measured with extreme care. The interest which inspires the safety movement is susceptible of misconstruction and, when once started, patience and persistence are necessary to overcome recognized prejudice.

In its report of legislative and municipal enactments the new laws in Massachusetts, New York and West Virginia are mentioned. In commenting on these, the committee states that the invasion of constitutional restrictions is becoming more manifest, and the laws affecting street railway organizations continue to savor of class legislation. If this principle is to be accepted by railroads, their influence in the framing of such laws should be exerted aggressively to prevent enactment.

Recommended practice for handling bulletin boards, which was one of the subjects assigned to this committee, indicates clearly a tendency to dissatisfaction with the results secured by existing methods. Recommendations governing notices as distinguished from bulletins, provide for the display of notices on the bulletin boards and their removal when obsolete. Bulletin recommendations provide that they shall be printed to conform in size with the rule book page, revised annually to include live bulletins in pamphlet form of the same size, and followed with a periodic revision of rule book every five years. On small properties where printing is not justified, individual issues should be supplied by using some established manifolding process. It was also recommended that bulletin discussions should be featured at periodic meetings and followed by inspection and examination. All notices should also receive like attention when their importance requires.

Regarding the methods of paying wages, the committee concludes that where various allowances are not involved and rates are fairly uniform, considerable merit attaches to daily payment by conductor or depot official from current receipts, using individual pay receipts as sub-vouchers to payroll which they accompany. This method was found desirable on properties of fairly good size, and it is also applicable to the largest properties if receivers are stationed at terminals to clear the conductors' daily receipts. While local conditions may make this method objectionable, weekly payment in cash by the paymaster should meet all requirements. Objections to unreceipted vouchers may be eliminated by requiring individuals to sign and deliver to the paymaster receipts for the payments made.

In the report on standardization and use of training schools, instruction cars and apparatus, it is stated that the data indicate that standardization is desirable. The best argument which could be advanced in support of uniform practice lies in the fact that extreme variations exist. Until each superintendent studies wherein his own practices are fundamentally wrong in principle but little may be accomplished in the way of securing uniform practice throughout the country.

Training schools are a necessary adjunct to all properties, irrespective of size. Employees should be taught their duties thoroughly, be made to realize the importance of work carefully performed and without ridicule or rebuff, be afforded opportunity to reach a thorough understanding of what is required of them. In order to accomplish this result personal attention of a painstaking order is necessary. A specific time should be devoted to this and a specialized effort made, uninterrupted by other administrative duties.

Regarding the use of instruction cars, the committee concludes that where operation is in congested territory, an instruction car is regarded as an essential part of the instruction methods. Its use, however, should be confined to rudimentary practice in the early stages of instruction. The necessity for instruction apparatus is believed to exist, the quantity and manner of display, however, being dependent upon the extent of use to which it is put.

For small properties the committee believes that a superintendent, depot master or inspector should be assigned to the work of instruction and that one man should do this work rather than several. A surface car upon a siding may serve as a school and by its use accurate operation may be required followed by platform instruction and supplemented by explanation and questioning to insure thorough understanding.

On medium-sized properties a permanent instructor with assistants, whose number depends upon the number of employees to be trained, should be provided. Owing to the number of students and the inability to give personal supervision, methods involving the use of forms and instruction blanks will be necessary. The number of cars used for instruction should be increased to meet required needs. Instruction apparatus should be displayed in greater detail and various parts indicated in such a manner as to make up for the reduced personal attention. Instruction plants for the large systems differ only from the former in the size, the essential features being the same, but with a larger supervisory staff.

ACCOUNTING TREATMENT OF DEPRECIATION

The address on the subject of the accounting treatment of depreciation delivered yesterday by Robert Sealy, assistant treasurer the North American Company, New York, before the Accountants' Association, treated the subject primarily from the point of view of "insurance replacement" rather than from that of the wasting of assets. The tenor of the address was to the effect that the extent of accounting provisions for depreciation and their importance is largely dependent upon the financial policy of the electric railway in question. There has been a rather general attempt on the part of regulating commissions to enforce accounting practices insuring the financing of future replacements, and it seems generally recognized that replacements are properly to be charged against income and not to be capitalized. Of all the methods for making such charges against income, the accrual method or charge against income during the preceding years appears preferable. Where regular charges to income are not separately accrued the surplus may provide the necessary reserves to insure replacement.

Mr. Sealy deplored the serious confusion of terms which has arisen in connection with the subject of depreciation and said that there is no part of accounting procedure so in need of standard definitions. In regard to the line of demarcation between charges to maintenance and charges to the reserve accrued for replacements, it seemed essential that charges to the reserve when based upon the anticipated life in service should be made only when the replacement effected actually adds to the life of the unit. Mr. Sealy condemned the practice of deducting the depreciation reserve from the asset account on the balance sheet as being a departure from the underlying theory of original cost and the substitution therefor of the theory of present value with its accompanying confusion. It would be better practice to treat the reserve as a liability. When reserves to insure replacements were accrued from income, Mr. Sealy felt that there was no necessity for separately funding the assets offsetting the reserve liability. Various methods had been suggested as a proper means of equalizing the charges against revenue, but pending the accumulations of mortality data it served no particularly useful purpose to draw fine distinctions between them, for all were presumably destined toward the same end. Mr. Sealy suggested that eventually the application of the principles of insurance to the calculation of the annual premiums or reserve credits would give figures more nearly representing the actual cost than would the assumptions involved in the application of the ordinary sinking fund or straight line methods.

One of the most interesting sections of the address dealt with the distinction drawn between the engineer's problem of appraising the present value of physical assets and the accountant's problem of accounting for the financing of replacements, and also with the description of the indeterminate nature of the engineer's task and the lines along which the accountant can proceed when the engineer supplies the essential underlying data. The accountant's problem is similar to and almost identical with that of the life insurance actuary who determines the premium to be paid by the insured under any one of a number of policy plans, but estimates on the annual reserve at present are far from accurate owing to the absolute lack of experience data with respect to the useful lives of various classes of property.

REPORT OF JOINT COMMITTEE ON ENGINEERING ACCOUNTING

The report of the joint committee on engineering accounting presented yesterday covered the three topics of overhead charges, inter-departmental charges and cost accounting. The committee did not take up in detail the subject of overhead charges, inasmuch as it is in the hands of a committee of the Accountants' Association. Such charges were defined, however, to cover costs over and above those of labor and material and directly and properly chargeable to a particular undertaking or piece of work. They comprise two distinct classes—first, those of an operating nature, including cost of supervision, administrative expenses, insurance, wear and tear on machinery, non-productive labor, etc.; and second, those of a more general nature, including interest, taxes, etc. Overhead costs are not susceptible of exact distribution and in general are estimates based upon and controlled by the conditions surrounding a particular case. They seldom, if ever, bear any fixed percentage relation to their respective costs of labor and material.

Inter-departmental charges were discussed from the standpoints of construction and operation. Inter-departmental charges for construction should properly include allowances for all overhead costs incidental to the work, and the Interstate Commerce Commission rule prescribed in the uniform system of accounts effective July 1, 1914, should apply in all cases. In the practical application of such a system, however, it is necessary to distinguish between the two classes of overhead costs previously mentioned, the proportionate amounts of only the first class being credited to the operating accounts of the departments doing the work, and the charges of the second class, representing return upon investment in plant and equipment used for the work, being credited to the accounts originally bearing the charges.

Such a system, if applied similarly to inter-departmental operating charges, would result in the inflation of the operating expenses by the overhead charges of the second class. On the other hand, inter-departmental operating charges under a system of including costs of only labor and materials would be inaccurate and misleading. A system of inter-departmental accounting in which the overhead costs of both classes were added to the job order cost (the department benefited by the work being billed with the total and the accounts of the department doing the work credited) would leave the total of operating expenses unaffected by the addition of overhead costs of both classes, since they would cancel in summation. Yet under this plan the department doing the work would be unjustifiably credited with an amount to cover fixed charges upon a portion of its plant and equipment, for it is not directly charged with an amount to cover the fixed charges on all equipment used by it. The inclusion of only charges of the first class would solve this difficulty, but no reason exists why the department benefited should be charged with the first class and not the second. The only solution of the problem lies in a system of cost accounting, summarized in a statement which is separate from the operating statement and in which the accounts of each department include its due portion of general expenses, taxes, interest, etc., and are then credited with the total cost (including labor, material and overhead of both classes) for work done for another department.

Cost accounting is defined by the committee as a separate and supplemental detailed analysis of accounts, designed to reflect the expenditures for different undertakings and various classes of work, as well as unit costs, with greater accuracy than is possible under systems of accounts prescribed by law. The essential features of the system outlined by the committee for both large and small companies follow: (1) preliminary estimate of cost; (2) actual or estimated original cost of work to be replaced, if any; (3) authorization through the proper official for the expenditure of the amount of the estimate; (4) formal notice of completion from the engineering department to the accounting department; (5) final statement of actual cost authorized by the accounting department; (6) supplemental authorization covering over-expenditures, if any; (7) certificate of completion, canceling unexpended balances, from the accounting department to the authorizing officials. This system insures the retention of all original records in the accounting department, and it can be used as a basis for increased economies of operation and valuable data for future estimates. In conclusion, the committee recommended that consideration of the subdivision of the maintenance expense accounts under the new Interstate Commerce Commission system be referred to next year's joint committee.

THE WAR AND PUBLIC UTILITIES

The September number of *Bonds and Mortgages*, Chicago, contained an article on "The War and Public Utilities—The Outlook for Investor and Public under New Conditions," by William H. Hodge, publicity manager H. M. Byllesby & Company. Mr. Hodge believes that well-managed public utilities will withstand the present strain on capital to far better advantage than most industries, pointing out, however, that "if a situation arises where a corporation will be saved from serious embarrassment by the application of surplus earnings to construction needs, rather than to the payment of dividends, the stockholders should have no grounds for criticism. Cases such as this will be comparatively rare in the American publicity field, and there is nothing in them warranting lessening of confidence on the part of investors in the securities of public utility companies under responsible and capable management." Mr. Hodge observes that public utilities deal with the law of averages. They can go through calamities affecting society just as cities and states persist in the face of blows which wipe out individuals and individual enterprises.

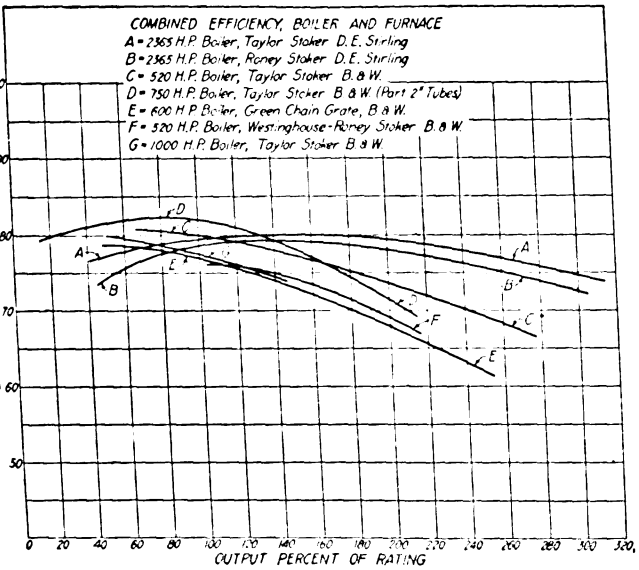
REPORT OF COMMITTEE ON POWER GENERATION

The report of the committee on power generation of the Engineering Association was presented yesterday. It consisted of three monographs prepared as sub-committee reports as follows: "Status of Automatic Stokers," by R. J. S. Piggott, mechanical construction engineer Interborough Rapid Transit Company; "Control and Safety Devices for Power Stations and Feeder Circuits with Special Reference to Reactance," by J. W. Welsh, electrical engineer Pittsburgh Railways, and Fay Woodmansee, Woodmansee & Davidson, Chicago, and "Advantages and Disadvantages of Sixty-Cycle Apparatus with Particular Reference to Rotary Converters for Railway Service," by L. P. Crecelius, superintendent of motive power Cleveland Railway, and W. H. Sawyer, Ford, Bacon & Davis, New York.

Mr. Piggott reported that the principal considerations in the design of a stoker are: (1) Coking of green coal; (2) adequate mixture and heating of volatile matter with air; (3) burning of fixed carbon; (4) disposal and dumping of ash and clinker. Other points, only less important than the first four are: (5) prevention of sifting, and (6) prevention of clinker adherence to brickwork and stoker parts. He considered the qualities of the three types of stokers; overfeed, chain grate and underfeed.

In the matter of costs his conclusion is that the comparative prices of the various stokers per rated horse-power of boiler are of little value unless the forcing capacity, maintenance and labor attendance are taken into account. The accompanying table gives average data for representative types. The costs per horse-power are averaged for each case; the forcing capacity is that obtainable with first-class operation and adequate draft in glowing apparatus. The maintenance figures cover stoker only. The maintenance of brickwork on overfeeds is usually higher than underfeeds on account of the expensive and troublesome coking arches. The same clinker adherence occurs in each, but is more pronounced in the underfeeds. The field narrows down to chain grates for high volatile high ash coals, and the gravity underfeed for practically all other classes. It is not certain but that the underfeed will eventually take the whole field.

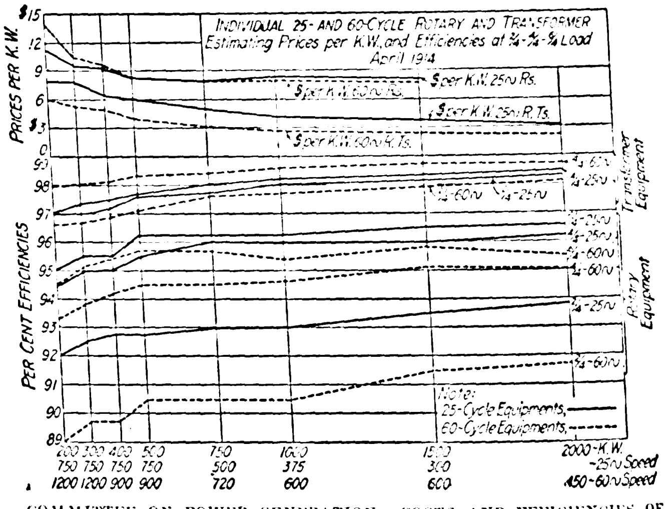
Stoker	Type	Average Price Per Rated Boiler Horse-power	Normal Forcing Capacity, Per Cent Rating	Draft	Price Per Maximum Horse-power	Maintenance Per Ton Coal (Dollars)	Man—Hours Attendance Per Active Hour	Pounds Coal Per Square Foot Grate Surface (Maximum)
Step and slope grates............	Overfeed	$3.60	190	Natural	$1.90	$0.10- $0.12	0.45	35-38
V grates...........................	Overfeed	3.60	175	Natural	2.06	0.11- 0.14	0.45-0.50	35-42
Chain Grates.....................	Overfeed	3.50-6.55	260	Natural and forced	2.52	0.06- 0.10	0.20-0.30	45-48
Gravity underfeed	Underfeed	5.65	300-350	Forced	1.88-1.62	0.025- 0.04	0.08-0.10	60-75
Horizontal retort underfeed......	Underfeed	4.44	300	Forced	1.48	0.04- 0.06	0.30-0.40	50-65



COMMITTEE ON POWER GENERATION—CHART SHOWING STOKER EFFICIENCY CURVES

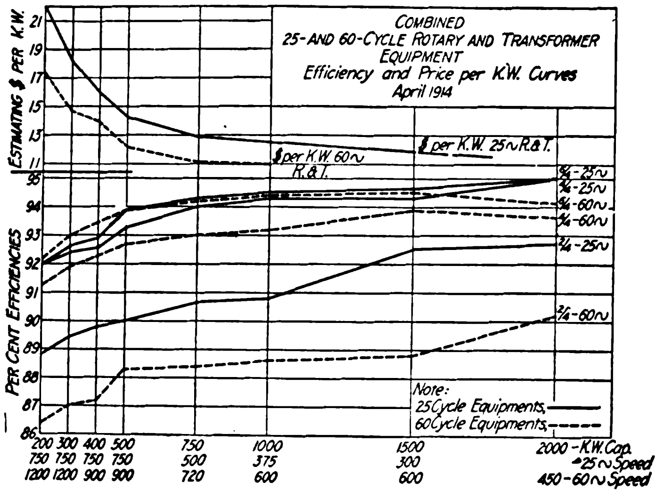
Mr. Piggot summarizes the data of efficiency of various modern stoker installations in the accompanying figure. These curves are for boiler efficiency only, not allowing steam for blowing or driving stokers, or for boiler feed pumps. All except the double-fire Roney stoker show best efficiency at less than 100 per cent boiler rating. Referring to the input-output line, it will be seen that the net output of steam is lower at any given coal input by the amount of steam used for auxiliaries necessary to operate the boilers. This in turn lowers the net boiler-plant efficiency by an amount which varies for every case. It will be found that the highest point of the new efficiency curve has been raised 20 to 25 per cent more in output than the highest point of the boiler efficiency curve. This indicates that the boilers should be run averaging about 25 per cent higher than the most efficient test point, viewed from this consideration only. But the principal factor influencing the load to be carried on the boiler is the relation of fixed charges to operating cost.

Messrs. Welsh and Woodmansee devoted their article to a discussion of the fundamental principles of the part played by natural and artificial reactance in power plants and transmission lines, particularly as affecting short-circuit currents, load distribution and synchronizing power of synchronous apparatus. They took up reactance location in generator mains, busbars and feeders and gave curves of the short-circuit currents produced under various conditions, and of the mechanical strains in reactance coils resulting therefrom. Some useful data given are as follows: Approximate space for a twenty-five-cycle, 50-kva coil 0.6 cu. ft. per kva, and for a 500-kva coil 0.3 cu. ft. Corresponding costs are $12 and $4 per kilovolt-ampere. The following figures were given for sixty-cycle coils: 50-kva, specific volume 0.3 cu. ft. per kilovolt-ampere, unit cost $6 per kilovolt-ampere. The volume is given as low as 0.0175 cu. ft. per kilovolt-ampere



COMMITTEE ON POWER GENERATION—COSTS AND EFFICIENCIES OF TWENTY-FIVE-CYCLE AND SIXTY-CYCLE APPARATUS for a 475-kva coil, and the unit cost $1.46 per kilovolt-ampere for a 1200-kva coil. A number of photographs of modern reactance-coil installations were reproduced in the report.

The paper by Messrs. Crecelius and Sawyer reviews the present status of sixty-cycle apparatus, particularly as contrasted with twenty-five-cycle apparatus. They stated that under normal operating conditions there is little choice between the two frequencies as far as turbo-generators are concerned, except that with high-speed generators the regulation may not be quite as reliable in the sixty-cycle machines when the load is variable. The damage from short-circuits also may be intensified. These machines are slightly more efficient and they are much cheaper, as are also synchronous motors built for the higher frequency. The same considerations hold with transformers.



COMMITTEE ON POWER GENERATION—COSTS AND EFFICIENCIES OF TWENTY-FIVE-CYCLE AND SIXTY-CYCLE APPARATUS

The writers state that, while the sixty-cycle rotary is probably not quite as reliable as the modern twenty-five-cycle machine, it is more so than the older ones and is reliable for ordinary conditions. The general tendency to hunting and flashing has been reduced by improved design. The present high speed permits the use of 8½ in. to 9 in. between commutating points and this, combined with commutating poles, improved mechanical design and copper dampers or cage winding, has resulted in the production of a sixty-cycle converter which approaches the twenty-five-cycle one in commutating ability. Hunting tendencies have also been reduced through the elimination of the reciprocating engine.

Under abnormal power supply conditions the sixty-cycle rotary is more sensitive to flashing than the twenty-five-cycle one, as it is also in case of d.c. short-circuits. Commutator speeds must be higher to give the necessary distances between commutating points, but as the current per brush arm is smaller, on account of the larger number of poles, the commutators can be made shorter. Sixty-cycle machines also run cooler, temperature limitations being not one of the controlling considerations as in twenty-five-cycle machines. From the standpoint of efficiency the twenty-five-cycle rotary converter is slightly better, but the advantage is neutralized or even reversed when transformer efficiency is included. In the matter of price the two types are nearly on equality in large sizes, with the sixty-cycle rotaries ahead in moderate and small sizes. The report includes numerical data bearing out the statements. Much of this information is shown in the accompanying diagrams. (The reader is referred for further information to articles based on data furnished by Mr. Crecelius and published in the issues of the ELECTRIC RAILWAY JOURNAL for April 5, 1913, page 618, and March 28, 1914, page 713.)

REPORT OF COMMITTEE ON COST OF PASSENGER TRANSPORTATION SERVICE

The committee on cost of transportation service, American Electric Railway Association, submitted its report yesterday. Much of the report discussed the organization and activities of the association's bureau of fare research organized May 1, 1914 (see ELECTRIC RAILWAY JOURNAL of May 9 and May 16, 1914). At present the bureau receives monthly reports from about 100 companies outside of New York and Chicago, the operating revenue of which amounts to more than $205,000,000 a year, which is about 40 per cent of the operating revenue of the entire industry. The results disclosed did not make possible generalized comparative summaries but they did reflect the present tendencies of business depression and indicated decreases in revenue at a greater rate than decreases in the cost of operation. The committee urged that more companies file statistics promptly with the bureau in order that the association could point out to the public the changing relations between revenues and the expenses more frequently and forcibly than is possible when reliance must be placed on yearly manuals and census bulletins.

The bureau had co-operated with the committee on standards for car loading in collecting information and had also made a somewhat extended study of the cost of rush-hour service, and results from the studies to date appeared in the report of the committee named. The bureau had also prepared a syllabus of the New England situation where some companies had increased the fare from 5 cents to 6 cents. At the instance of a member company it is also gathering information about rates of fares charged by neighboring interurban companies for use in an action looking toward an increase in rates of fare. Furthermore, at the request of the committee on compensation for carrying United States mail, the bureau is compiling data on handling all material of electric lines.

The committee then mentioned the investigation of maximum length of profitable ride conducted jointly by the Boston Transit Commission and the Public Service Commission of Massachusetts (see ELECTRIC RAILWAY JOURNAL of Aug. 1, 1914). In commenting on its figures the committee said it was very much to be doubted whether a passenger riding 2.86 (two-thirds of the round trip of 4.28 miles) would cost the company only two-thirds as much as the one riding to the end of the line, for the cost of handling a passenger does not depend entirely upon the length of the ride. Under the assumptions and figures of the joint commission, it appeared that a charge of 5.25 cents instead of 5 cents would raise the earnings from 5.4 per cent to 7 per cent and that the earnings might be further raised to 8 per cent by an increase to 5.38 cents per ride. The committee added that the work of the joint commission was an instance of the growing interest in the field of work assigned to the bureau of fare research. The fact that in the year 1912 passengers were using electric railways ten times as frequently as steam railroads, double the ratio of 1900, indicated the increasing importance in the relations of the public to the electric traction industry and the need for a clearer understanding of the economic problems of that industry.

The expenses of the bureau had been somewhat less than the amount authorized by the association, but this did not indicate that the authorized amount was greater than the later needs of the bureau. The original plan provided for the annual appropriation by the association of $2,500 for three years, and that $5,000 a year for each of the three years should be obtained from the member companies interested. As the bureau did not begin its operations until May, and since the initial expenditures of the bureau had been low, it had been decided to date the pledges to the support of the bureau from June 1, instead of from Jan. 1, 1914, as originally made. For the five months, May to September inclusive, the expenses of the bureau had been about $2,500. The association had expended in behalf of the bureau from its own funds $2,000 and had received contributions from member companies of $1,000.

REPORT OF 1915 CONVENTION COMMITTEE

The 1915 convention committee of the American Electric Railway Association presented a progress report yesterday. It reported that at a meeting held at the association offices on Feb. 25, 1914, the then existing status of arrangements for hotel and convention headquarters accommodations had been presented. By reason of the expressed attitude of the San Francisco Hotelmen's Association, it was determined necessary to ascertain so far as was then practicable, the probable number of delegates who would attend the 1915 convention. The secretary had been instructed to prepare and send out a letter requesting information as follows: Number of delegates definitely guaranteed; probable number of additional delegates; date of arrival in and departure from San Francisco; kind of room desired, indicating, if possible, double or single room, and with or without private bath; if ladies will accompany members of the party, they should be included in the number to be guaranteed or in the number probably in attendance from each company.

As of July 3, data blanks had been sent to members and replies requested. The number of replies received to date had not been sufficient to develop a satisfactory basis for the making of hotel reservations.

At its meeting referred to the committee had recommended to the president of the association that he appoint a chairman of a committee on transportation, the chairman in turn to appoint the other members of the committee. It had also recommended that the Manufacturers' Assosiation appoint a similar committee to co-operate with the committee of the American Association.

THE INTRAMURAL RAILWAY AT THE SAN FRANCISCO FAIR

Of the several means to be taken to eliminate the bugaboo of leg-weariness from the grounds of the Panama-Pacific International Exposition during 1915, the most elaborate and effective will be the little intramural steam railway, with its 5 miles of steel track, work on which was begun on Oct. 1. The steam locomotives to be used will be 17 ft. in length, similar except in size to the standard modern Pacific type of engines and will be equipped with air brakes, standard automatic couplers, electric headlight and six drive wheels. Each engine will haul a train of ten miniature passenger cars of a gage of 19 in. The cars themselves will have a width of 42 in. and a length of 20 ft. and will contain ten transverse seats to seat twenty passengers each. With ten such cars to each train and eight trains in operation, 1600 people can be put in motion at once. Conforming to city speed regulations, the trains will make only about 10 m.p.h. between stations, of which there will be seven including three terminals, elaborately fitted up with train sheds, elevated platform and turntables. The entire line will be 2½ miles in length, double track and built with rails weighing 40 lb. per yard.

In consequence of such a large number of men in the employment of Belfast (Ireland) Corporation Tramways having joined the colors and of the traffic receipts having fallen by about £500 per week, Mr. Nance, the general manager, has found it necessary to reduce the number of cars in service during the quiet hours of the day. The number of cars during the busier hours has, however, been increased.

REPORT OF COMMITTEE ON COMPENSATION FOR CARRYING UNITED STATES MAIL

This report, submitted in manuscript, was most voluminous. It refers first to a statement sent by the committee under date of Dec. 11, 1913, to Judge Moon, chairman of the House committee on post-offices and post roads. An abstract of this letter was published on page 1337 of the Electric Railway Journal for Dec. 27, 1913. It was accompanied by estimates prepared by the Boston Elevated Railway and the Brooklyn Rapid Transit Company as to the cost of the operation of mail cars on those systems. The letter complained of the lack of the compensation paid by the government to the electric roads for carrying mail and asked for relief.

The committee then states that while it was making efforts to convince the two committees in Washington of the justice of the claims of the railways, individual companies were also carrying on negotiations. Among these were the Lehigh Valley Transit Company and the Cincinnati Traction Company, which, however, were not able to secure relief. On the other hand the Pittsburgh Railways were more successful in their negotiations with the Post office Department and succeeded in securing added compensation by computing the length of their cars on the basis of the entire inside length rather than the length between bulkheads by removing the bulkheads, and while their rate remains the same, that is 1 cent per foot of length of car body, the length of car body in computation was so increased as to materially add to their compensation per car-mile, so that the rate received by this company was approximately 25 cents per car-mile for a standard 16-ft. car body with two 5-ft. platforms. The Boston Elevated Railway, in endeavoring to secure added compensation, was advised by the department that "relative to the question of increasing the length of the mail cars used by your company in the performance of service on route 304,001 at Boston, you are informed that the conditions of the road have been carefully investigated and it is found that the present authorized facilities appear ample for the proper performance of the service."

An account was also given of the extended negotiations of the Connecticut Company with the government. These finally resulted in the decision of the Connecticut Company not to carry the mails any longer. An account of the situation, with the copy of the letter addressed by the Connecticut Company to the government, was published on page 1470 of the Electric Railway Journal for June 27, 1914, and also appeared in the report of the committee.

The Brooklyn Rapid Transit Company, in its negotiations with the Post-office Department, advised the second assistant postmaster general, on May 7, 1914, that the compensation to the company for carrying United States mail was unremunerative "and the continuance of this service under present conditions cannot be justified, and unless conditions can be complied with and authorized by the Post-office Department which will warrant our continuing the service it will be necessary, after reasonable notice, for this company to discontinue our service of carrying United States mail in independent cars." After investigation on the part of the Post-office Department and negotiations between the two parties, the railway company discontinued all mail service. The committee adds that there may be and undoubtedly are cases where other electric railways have had negotiations with the Post-office Department during the past year of which the committee is not informed.

In the meantime, Senator Bourne's committee was investigating the whole question of compensation for carrying United States mail and on Aug. 31, 1914, published "Report of the Joint Committee on Postage on Second Class Mail Matter and Compensation for the Transportation of Mail." The recommendation of the committee included a bill to increase the railroad mail pay about $5,000,000 a year and expressed the opinion that mail transportation should yield a car-mile revenue approximately the same as passenger service because conditions and expenses are similar. In the report Chairman Bourne complains of the vacillating policy of the Post-office Department which, he states, has changed its proposed method of payment four times in four years. He ascribes much of the delay in preparing the report to this fact. The report quotes variations in the department's estimates of alleged overpay of the railroads from $10,531,792 down to $221,832. One paragraph reads: "Before closing this report we deem it our duty to inform Congress that our work has been greatly handicapped by the deplorable lack of definite information in the Post-office Department regarding its own operations and by the attitude of the representatives of both the Post-office Department and the railroads. On both sides there has been a persistent tendency towards special pleading. From the beginning the railroads have been opposed to the adoption of space as a substitute for weight as a basis for mail compensation. On the other hand the Post-office Department has evinced a determination to secure a reduction in the total amount of railway mail pay, with little, if any, regard as to whether or not such a reduction is justified under prevailing conditions."

The report further states: "Representatives of the railroads are open to similar criticism. A reading of the evidence will show that they were either not in possession of very definite data or they were reckless in their computations showing the amount of under-payment they believed existed. Their estimates of under-payment vary from $15,000,000 to $38,000,000."

On Aug. 25, 1914, Senator Bankhead introduced Senate Bill 6405 "authorizing and directing the Postmaster General to readjust compensation of steam railroad companies for the transportation of mail."

Aside from the increased compensation provided in this bill, it should be of interest to the delegates to note the following extract, Section 7: "After the rate specified in this act shall have been in effect for a period of two years, the Interstate Commerce Commission shall, whenever requested by the Postmaster General or the representatives of the railroads with an aggregate mileage of at least 25 per cent on the railroads carrying mail, make an investigation of the justice and reasonableness of rates as in effect, grant hearings to parties in interest, and report to Congress at the earliest practicable date thereafter the results of such investigation, making specific findings as to whether the rates fixed herein shall be increased or decreased and, if either, how."

"Section 9.—That it shall be unlawful for any railroad company to refuse to perform mail service at the rates of compensation specified in this act when required by the Postmaster General so to do, and for every such offence it shall be fined not exceeding $5,000. Each day of refusal shall constitute a separate offence."

On Sept. 11, 1914, the committee forwarded to Senator Bourne a communication requesting information as to what his committee had in mind relative to the cases of the electric railways. On Sept. 12 Senator Bourne replied to the committee in part as follows:

"Referring to your letter of Sept. 11 as to why a committee of that association was unsuccessful in securing consideration for the electric roads similar to that of the steam roads; when this committee began its hearings it had before it two plans submitted by the Post-office Department for compensating both steam and electric lines for carrying the mails, the first having been submitted to Congress on Aug. 12, 1912, and the second, a modification of the first, to our committee on Jan. 20, 1913, both being what has been frequently denominated a space-cost plan.

"When representatives of your association appeared before our committee on Feb. 7, 1913, we expected them to discuss the modified plan of the Post-office Department, with which we supposed they were familiar. It developed that they were not familiar with its provisions and their testimony was directed more to a demonstration that they were underpaid rather than the submission of a plan which would do substantial justice to both the government and the electric lines.

"Later, namely on Feb. 19, 1913, in response to my request, your Mr. Lyons prepared and submitted a bill, approved by your association, recommending among other things an increase of 0.5 cent per linear foot over the present pay. This bill was promptly submitted to the Post-office Department for an expression of opinion as to its merits, and on July 25, 1913, the Postmaster General submitted a memorandum prepared by Second Assistant Postmaster General Stewart in opposition to its provisions. In the concluding paragraph of the memorandum Mr. Stewart makes the following statement: 'The tentative draft of the proposed law for regulation of compensation allowed electric and steam railroads for the transportation of the mails, contained in House Document No. 105, as modified by letter of the Postmaster General dated Jan. 20, 1913, is believed to provide a scientific and equitable plan for the fixing of compensation for the carriage of the mails by railroads, both steam and electric.'

"Later the department abandoned this and submitted a new plan, same not being applicable to electric lines. The committee rejected both and prepared a bill embodying its own views as fully set forth in its report made to Congress on Aug. 31. As we progressed in our study we found that the conditions applicable to steam and electric railways were so different that they would have to be considered as independent propositions. It was and is not our purpose to neglect the electric lines, but action has merely been postponed on account of the consideration just stated, and this is indicated on page 122 of our report where we say: 'We have on hand a balance therefore, of $18,439.50 still available out of which to defray such additional expense as may be incurred in working out a plan for mail pay to electric roads, etc.'

"The committee has your association's suggested bill before it and it will receive due consideration before any action is taken. If it is your desire or that of other members of your association to present anything new before the committee we shall be pleased to receive it."

To this the chairman of the committee forwarded a reply assuring Senator Bourne that the committee would be glad to submit further information to him.

It would appear therefore that this convention should direct and authorize a duly appointed committee to assemble, prepare and submit further detailed information to Senator Bourne's committee.

The electric railways are peculiarly fortunate in now being in a position to benefit by the experience of the steam railroads as well as by the report and bill submitted by the Senate committee, and in presenting their case the committee should be particularly careful to be so informed and to have such statistics as will prevent any possible criticism by the commission similar to that to which the steam railroads were subjected. The committee in submitting this report is of the opinion that the electric railway companies' case was never in better condition than at the present moment and that prospects are bright for it to receive fair and patient consideration by a judicial body peculiarly well qualified to render a report and recommendation consistent with facts and conditions.

Prof. John R. Wildman, head of the accounting department of the New York University School of Commerce Accounts and Finance, who on Tuesday delivered the address on accounting education, is the author of two valuable books on accounting, one a short treatise, called "Cost Accounting," and the other an exhaustive work, entitled "The Theory of Accounting."

THE RECONSTRUCTED FORT WAYNE PLANT

Discussing editorially the problems involved in the reconstruction of the double-decked generating station of the Fort Wayne & Northern Indiana Traction Company in Fort Wayne the *Electrical World* said in its issue of Oct. 10, 1914:

"Rebuilding an electric station without interruption of service is always a feat involving much ingenuity and sometimes a very high degree of engineering skill. The station reorganized had been built only seven years and when constructed gave promise of exceptionally good results. It was of the double-decked type with the turbines on the second floor directly over the boilers, an arrangement which in principle is a good one, leading to short steam connections and an economical design of station. In this instance, however, an amount of vibration developed which made reconstruction and abandonment of the double-deck scheme imperative, and when the conditions of load demanded an increase in equipment advantage was taken of the opportunity to make a complete change in the arrangement of the units and thereby remedy the existing trouble.

"The plant contained both twenty-five-cycle and sixty-cycle generators, and the increasing load demanded an increase of sixty-cycle equipment which was met by the installation of a pair of 6250-kva turbo-generators. To accommodate these a building was erected alongside the original station with its turbine floor on the level of the old. boiler floor, and a basement was provided for the auxiliaries. The result was a new and efficient plant for the sixty-cycle service, the new turbines being more efficient than the older ones. The main twenty-five-cycle machines had to be moved without interrupting the service on the railway lines to which they fed energy. At least one of these had to be in operation all but continuously except during periods of the very lightest load. The railway turbines were dismantled one at a time, and the pieces were carefully lowered by the traveling crane through a hole in the turbine-room floor, loaded on a flat car and shunted around to the new portion of the station. The ground-floor equipment of auxiliaries was then transferred to the new turbine room, and the whole equipment was put to work without interruption of service, leaving all of the active generating equipment alongside the boiler room in the new building. The old turbine floor was then put to good use by placing in it substantially all the control and switching apparatus for the station, and also installing there three large motor-generator sets, two used for the direct feeding of the railway lines and the third as a frequency changer to enable the night load to be carried from the sixty-cycle generators.

"One specially interesting feature of the new portion of the plant is a corridor in the basement for the entrance of cooling air for the generators. After passing through the generators the warm air is turned into the boiler room through suitable ducts. Two of the large condensers and some of the auxiliary appliances as well are installed in this air corridor, and the large entrances into it under the turbo-generators serve to limit to the basement a considerable amount of the noise from the machines which otherwise would be perceptible in the turbine room itself."

COMMERCIAL ATTACHÉ TO STUDY CHILIAN TRADE

Verne L. Havens, consulting engineer and for a number of years chief engineer of the Mexican Tramways, has been recently appointed commercial attaché of the Department of Commerce. Mr. Havens will proceed to his station at Santiago, Chili, some time next month. He will study out means for improving and developing American trade with the country to which he is assigned.

"Chili offers a first-rate market for the goods which we produce in the greatest quantity," says Mr. Havens in the New York *Evening Post*. "She has to import all her coal and timber, cotton and refined oil. And those are four articles in the production of which this country is a leader. Last year Chili took 113,000 tons of coal from us, but previous to this she had dealt mostly with England and Germany; and of course the long sea voyage has made coal extremely expensive. It has been $10 a ton in normal times; to-day, it is much higher.

"There seems to be no reason why this country should not supply a great portion of Chili's coal at a much lower rate, now that the Panama Canal is completed and communication between our Eastern and Gulf Coast ports and the West Coast of South America is simplified. This applies not only to anthracite, but to soft coal, of which latter grade enormous quantities can be used. It seems to me that this offers an opportunity for the Alabama, Tennessee, and other Southern soft-coal fields.

"Then, take timber. There is practically no timber in Chili. It must be imported. They have been taking a great deal of Douglas fir from our Northwestern States, but now they will be able to get yellow pine from our Southern States shipped through the canal. Douglas fir is a very good wood, adaptable for house-trimming, and so forth; but it is rather soft. A tough woodlike yellow pine will be extremely valuable to the Chilians for heavier construction, for bridge building, car sills, and similar things. All of the cotton goods that the Chilians wear they must import, and as I have said, they have no refined oil. Besides this, although they have great resources in crude iron ore, they produce no steel. I understand the Bethlehem Steel Company is planning to operate down there.

"It is a very delicate matter to develop trade with a foreign country. At best, trade is an elusive quantity. Much depends upon the spirit in which the campaign is launched. It does not pay to create an impression in a country that you expect to win its trade simply because it has no other resource, and must buy from you or from nobody. All peoples are proud, and they require, and have a right to require, consideration and the manifestation of a spirit of conciliation and cordial desire for co-operation."

BALANCE OF TRADE FAST TURNING IN FAVOR OF THE UNITED STATES

"From the figures which I have received on the import and export trade between the United States and foreign countries," stated Andrew J. Peters, Assistant Secretary of the Treasury, in charge of customs, in the New York *World*. "I am confident that the balance of trade in favor of this country will exceed even the most sanguine predictions made prior to and after the beginning of the European war."

"On Oct. 10 of this year our imports from foreign countries amounted to $3,303,700, while our exports were $4,121,812. On Oct. 12 our imports were $272,996, while our exports were $487,357. This was an unusually small percentage of day's receipts compared with the month. But on Oct. 13 the imports were $5,582,830, while the exports amounted to $6,707,243.

"The total amount of imports from Oct. 5, according to the figures in my possession up to the present date, are $33,271,857, while our exports during the same period amount to $39 840,816.

"The ports of New York, Boston, Philadelphia, Baltimore, Newport News, New Orleans, Galveston, San Francisco and Chicago represent 87 per cent of our import trade and 72 per cent of our export trade. My calculations are based upon reports which I have received from the collectors of customs at these ports, which indicate conclusively that the United States is beginning to feel the effect of the depression in the markets of Europe and is selling all kinds of products to those nations now engaged in war, resulting in a balance of trade in favor of this country which is bound to have its effect upon the present strained financial situation.

WHY THEY ARE CALLED "WINNER" SEATS

Foremost among the car seats exhibited by The J. G. Brill Company this year is the improved "Winner" type. The improvement in the construction of this seat consists chiefly in using double levers at both ends, making it more substantial than ever and capable of standing rough handling by conductors hurrying to change over at the end of the route, or by passengers of large dimensions forcing themselves back by pushing against the foot rails or seat backs. This type of seat is shown with woven cane upholstered cushions and backs, and slat backs; also with high, three-part back and arm rest for interurban car service. For interurban service the double lever at each end gives the strong support necessary for the high and heavier back. The "Winner" seat is constructed with pressed-steel one-piece pedestal, pressed-steel one-piece aisle and wall plates, angle-steel cross frames, and the backs have springs as well as the cushions. The Brill standard stationary back seat has the pedestal and aisle end arm made of pressed steel in one piece; there are no cross frames and therefore when the cushion is lifted out only the pedestal and back remain, leaving a free space for sweeping the car. Rolls of lined and unlined twill-woven cane manufactured at the Brill plant by improved processes are exhibited. Three types of motormen's seats of both adjustable and non-adjustable types are also shown.

MULTIPLE-UNIT FREIGHT TRAIN OPERATION

The Empire United Railways, Inc., will shortly place in service five new freight cars to take care of a large increase in its freight business. In this connection Ernest Gonzenbach, general manager, contemplates a new idea in freight traffic arrangements. The equipment for these cars was specified to be Westinghouse No. 333-E railway motors with automatic battery unit switch control to operate in trains. Instead of operating single freight cars, affording too frequent service, the plan will be to operate in two and three-car trains, thus approaching more nearly steam traffic conditions. Thus, while the service rendered will still be superior to that afforded by steam railroads, the cost of operation will be such as to allow of profit at steam railroad rates.

STEEL POURED LIKE WATER WELDS PIPES WHILE YOU WAIT

Strollers in Machinery Hall yesterday were attracted by a lurid glare emanating from the Goldschmidt Thermit Company's space. On investigation they found that practical demonstrations of pipe welding were going on on a regular commercial scale, short lengths of 1¼-in. extra heavy pipe being joined together by the Thermit butt-welding method. This is the first time that the reaction has been demonstrated on the pier and it is certainly well worth seeing.

In using this process for pipe welding, the pipe ends are first accurately squared up by means of a pipe-facing machine designed for the purpose, and are then held tightly together by means of clamps. A cast-iron mold is placed around them at the joint, and into this is poured the superheated mass of slag and steel produced in half a minute by the Thermit reaction. The slag goes in first and covers the outside of the pipe and the inside of the mold with a protective coating which prevents the steel, going in afterward, from coming in contact with either the pipe or the mold. The entire mass, however, brings the pipe ends to a welding heat, at which time they are squeezed together by means of the clamps and a butt-weld affected. The entire operation is completed in from five to ten minutes.

After seeing one of these demonstrations it is easy to understand how, in rail welding with Thermit, the insert placed between the rails is butt-welded on each side to form a continuous rail head. It is also a liberal education to see Mr. Mann of the Goldschmidt Company handling this white hot steel and pouring it from crucible to mold as though it were as easy as drawing beer from a keg.

NEW ENGLAND COMPANY DISCARDS OPEN-BENCH CARS

The New England Investment & Securities Company is building twenty new cars for its properties—the Springfield Street Railway and the Worcester Consolidated Street Railway—and is using the electrical equipment from some of the open-bench cars which are being dismantled. This procedure permits the use of the latest type of cars without the large outlay of capital necessary for the purchase of an entirely new car. Following in the steps of the New York companies, the Security Company has equipped the cars with electro-pneumatic contactor devices of the Westinghouse HL type. The wiring is so arranged that the main line switch cannot be closed until the doors of the cars are closed, and if the latter are accidentally opened while the car is in motion the control circuit is broken and the power is shut off of the motors. These contactor devices have a further advantage in that the main power arc is broken beneath the car.

JOHNS-MANVILLE PROGRESS

The "safety first" 2500-volt fuses at the H. W. Johns-Manville Company's space 336 have excited much interest during the week. It is claimed that these fuses will absolutely operate on circuits of all capacities. In connection with these fuses, the company has recently developed a line of fuse boxes embracing types both for aerial and underground work. These boxes have been designed with the "safety first" movement in mind. The operator is entirely protected from live metal parts and contacts by porcelain carrier handles, which are left in the box permanently so as to make the operation of the fuse boxes at 2500 volts absolutely safe.

Ebony asbestos wood for switchboards and panel boards is also attracting much attention. This new material has been approved by the National Board of Fire Underwriters, for all places where slate, marble and soapstone have previously been used. Its dielectric strength is so great that it permits considerable reduction in thickness. Where 1-in insulation would ordinarily be specified, ¾-in. ebony asbestos wood is sufficient. Moreover, its mechanical strength is much greater, and it can be worked up with the tools ordinarily used by carpenters. It is made in various thickness from 1-in. and up, and in sheets of various sizes from 36 in. x 48 in. to 48 in. x 96 in. and takes a high polish.

J-M air-brake expander rings, which are a decided improvement over the old style air-brake cylinder packing expander rings, are also being exhibited. The trouble with the old type rings has been largely due to the leakage of air in the brake cylinder and unnecessary wear of the packing leather, resulting in reduced braking efficiency. With the new J-M expander ring these difficulties have been entirely overcome. The claims for this new ring are that it increases the life of packing leather, eliminates brake failure due to leakage, increases braking efficiency by utilizing the full pressure applied, prevents distortion and is very easy to apply. Other features of this company's exhibit include a full line of fuses, primary cut-out boxes, several kinds of "Vulcabestos" insulation and its well-known underground fiber conduit.

During the three and one-half years ended on June 30, the New York Central & Hudson River Railroad had not had a single train accident by which a passenger lost his life. During this period the company carried 136,000,000 passengers.

HIGH-VOLTAGE OUTDOOR SUBSTATION

By the happy combination of electrical and structural engineering the Railway & Industrial Engineering Company, in space 609, has developed and is exhibiting a unique line of out-door substation equipment. Besides showing this equipment mounted on one of this company's several standard T. E. substation steel structures, it is also exhibiting its lightning arrester and disconnecting switch equipment. The lightning arresters are particularly adapted to outdoor substations. The series horn-gap choke coil allows a 50 per cent wider gap to ground and provides the same protection as other types. A very important feature in this lightning arrester is the magnetic blow-out which accelerates the travel of the arc up the horns. Recent improvements in this lightning arrester equipment include the insertion of resistance in the ground circuit to limit the flow of dynamic current which might otherwise be experienced if two phases discharged simultaneously.

The disconnecting switch, known as the Burke horn-gap and designed to open under load and at same time protect the main contacts from burning, is also attracting much attention. Recently tests were conducted where this switch opened very satisfactorily under loads of 4000 and 5000 k.w. at 50,000 volts. Oscillograph records taken during these tests showed conclusively that no surges or line disturbances were created. In general the main blade of the switch is carried on two insulators so as to avoid any torsional strains which might loosen them between sections or on the pin. The new type of main contact developed for this switch is entirely weatherproof. It consists of a flexible leaf brush and contact block so arranged that in closing the switch a wiping motion is obtained which keeps the contact clean, and a sleet hood covers the entire contact. The drop-forged operating mechanism provides for easy adjustment. The low-voltage side of this out-door substation is operated with a weatherproof oil-switch and the new suspension type lightning arrester. A steel cabinet box houses the metering equipment.

THE CLEAN WAY TO CLEAN CARS

The application of vacuum cleaners for cleaning cars and for all sorts of cleaning around carhouses and stations is being demonstrated by the Western Electric Company. The cost of cleaning cars is a very large item in operating expense. With some companies it actually exceeds the costs of mechanical and electrical maintenance and repairs. The heavy and diverse character of the dirt and litter which packs into the car slats, and is sometimes wet down by dripping umbrellas and wet feet, makes a very exacting job for a suction cleaner, and this company has spent a great deal of time and effort in solving the problem.

The high power Western Electric cleaner, with a special large hose and brush tool especially designed for slatted car floors, is believed to do this work better, more quickly and at a less cost per car than the broom and brush method. It picks up transfers, cigar butts, peanut shells, street dirt and all sorts of litter left in the car excepting full-sized newspapers. It is in use by some of the largest and most progressive roads in the country.

F. J. S. Hosken, general manager Darwen (England) Corporation tramways, has instituted a miniature rifle club, the object being to teach men how to handle a rifle and to shoot straight. The range, which is situated in a large room under a billard hall, was formally opened by the Mayor. Mr. Hosken is acting as honorary secretary, and he has the support of a strong committee. There is no charge for membership, and ammunition is supplied at ten shots for 2d. Rifles are provided and instructors have offered their services.

Among the Exhibits

W. R. Gorton, who among other things is now talking highway crossing protection, was busily engaged yesterday in driving home the good points of the apparatus of the Protective Signal Manufacturing Company of Denver, of which Will is general sales manager and associate engineer.

* * *

Charles B. McLeer and Joseph F. McLeer are attending the convention in the interest of the McLeer Electric & Manufacturing Company. This company has recently added a number of new devices to its old line of manufacture and is now operating in the electric railway and lighting field.

* * *

The flexible gear at the Nuttall exhibit, spaces 140-144, is the latest development in gears for railway service. These gears cushion all shocks on the gear teeth, due to rough track, emergency brake application or any inequality in motor torque. The result is an increased life of gear teeth, armature and axle bearings, commutator, brushes, brushholders, etc.

* * *

One of the most important features to be taken into consideration in working out car designs to meet local requirements is the air compressor. The most recent development in this line by the Westinghouse Traction Brake Company is a 16 cu. ft. compressor of minimum height and weight, known as D-1-H, which has been built expressly for low underframe cars, or wherever else space is valuable.

* * *

We understand that Tom K. Bell, chief engineer Atlantic Welding Company, New York, is inviting the railway managers and the engineers in particular to stop off at Ardmore on their way home, to see a demonstration of the Atlantic Welding Company's new electrically-welded joint at its laboratory at that place. Those wishing to avail themselves of the opportunity should get in touch with Mr. Bell, who is stopping at the Strand Hotel, room 611.

* * *

Pyrene again came to the front Wednesday night when a small fire was discovered at the outer end of the pier. The first thought of the man who discovered the fire was to obtain a Pyrene extinguisher. After making a run to the booth he found it closed but broke in and opened a box to obtain one. The same thing occurred Thursday except that the fire was in the main building.

* * *

An exhibit of special interest in the way of illustrating the advancement made in air-brake mechanism to meet present requirements, especially for subway and elevated service, is being demonstrated by the Westinghouse Traction Brake Company in the Main Building. This exhibit consists in a rack containing a complete air-brake equipment for motor car and is arranged to show the performance of the apparatus in every detail, whether controlled electrically or pneumatically.

* * *

Hubbard & Company, in space 618, feels that its mission in the electric railway and central station field is to teach the use of pressed steel brackets and cross-arms of commercial steel sections. Consequently the visitors to this exhibit have carried away a new idea for use in handling their overhead line problems. The Hubbard slogan is "Make brains do the work of surplus metals." A full line of Presteel specialities and standard pole line hardware which includes Presteel brackets and Bo-arrow arms are on exhibition. It was hoped that this company's new complete catalog would be ready for distribution at the convention. Unfortunately it was disappointed, but promises the delivery of the catalog in about two weeks. This company's plant does not confine itself to its own products but solicits the manufacture of small steel pressings of any description.

Electric Railway Journal

Consolidation of Street Railway Journal and Electric Railway Review

Vol. XLIV NEW YORK, SATURDAY, OCTOBER 17, 1914 No. 16

THE SUCCESS OF THE 1914 CONVENTION

In a time of general financial stringency, such as we are having at present, brought on by the catastrophe of the war in Europe, many fears were expressed as to the effect on the success of the convention. But they were not realized. It is true that the attendance was not quite so large as last year, especially as regards the roads at a distance, but most of the Eastern roads sent larger delegations than usual, and there was a marked earnestness on the part of the delegates in Atlantic City to obtain the most benefit from the trip. One general manager expressed the situation in our hearing as follows: "These are the times when the railroads must use every method and device which will produce a saving. Our gross receipts have fallen off 5 per cent, and it will be hard for us to maintain our usual 60-per cent operating ratio, but we are going to make every effort to do so. I felt able to send only one-half of the usual number of my men to the convention this year, but every man whom we have sent will make the most of his time, both among the exhibits and on the floor and will take back to those who did not come as much information to help them in their work as he can." The effect of this spirit, which seemed to be general, was evident throughout the convention in the earnestness with which the delegates participated in the discussions at the meetings and in the attendance at all of the sessions, which was noticeably larger than usual, and with the care with which they inspected the exhibits. The latter, as a whole, were equal, if not superior, in interest, to those shown in previous years, although they occupied about 5 per cent less space. In view of the attendant circumstances, the slightness of this falling-off is notable.

THE AMERICAN ASSOCIATION

The work during this past year of the American Electric Railway Association, as represented by the papers and reports at Atlantic City, was largely upon the subject to which our convention issue this year is devoted, that is to say, of public relations. The report itself on this subject was presented on Wednesday afternoon, and the sympathetic spirit with which it was received and the enthusiasm which its recommendation inspired showed that the necessity for prompt and vigorous action along these lines was generally realized. We have already discussed in our daily issue for Thursday the recommendations made by this committee as well as its proposed code of principles, and its suggestions should be carried out soon. Other notable papers and reports at the American convention were the address on valuation by Mr. Stevens, presented at the meeting on Tuesday, and the excellent reports on carrying United States mail, federal relations, cost of passenger transportation service, taxation and the most instructive paper by Mr. Stearns. This latter paper will be published in our issue of next week. Everyone who reads even cursorily the papers and reports presented at the meeting of the American Association will be impressed with the serious character of the problems with which the industry is face to face—problems which concern not only the industry but the public as well, because the interests of each community are necessarily closely associated with those of the utility which provides its transportation service. It cannot prosper if that is crippled and is unable to meet legitimate demands for transportation. With the larger fund which the association will have through the increase in dues decided upon at Atlantic City, its possibilities for doing more effective work are increased, and we look forward to an even more successful association record as a result of the coming year's work.

THREE CARDINAL INVESTMENT PRINCIPLES

In his address Wednesday on the company's point of view regarding electric railway securities, Calvert Townley brought out three principles which are at the foundation of the electric railway financial problem of to-day. They are as follows: (1) Railways must grow with the communities they serve, and the resulting additions and betterments required cannot possibly be financed out of the earnings; (2) security selling is competitive, and if electric railway securities are to be sold they must be comparatively attractive, in price and yield, and (3), financial and commercial conditions are constantly changing so that fixed rates of return cannot be expected to attract for a long term of years. The importance of these principles needs no demonstration among electric railway officials, but the problem is how to impress them properly upon the public mind. When citizens, legislators, congressmen and public service commissioners realize these facts, they will know that the imposition of one-sided bargains on electric railways will cause only a reduction of profits, a dearth of capital for needed extensions and a throttling of community growth. Naturally, electric railway securities should be among the most popular offered, and this has been largely the case in the past, but it cannot continue if capital is to be legislated into ever less remunerative or permanently blocked channels.

It is impossible to have too much publicity on these points. As one writer in our convention issue said, the company figuratively must live in a glass house for the exhibition to the public of its daily activities. Such a broad policy of publicity, bringing to public view the company's side of daily operating problems, is certainly most desirable. Yet the term, as Mr. Townley used it, and as we used it above, refers also to that more intangible but eminently desirable process of education whereby the public mind is gradually attuned to a proper appreciation of fundamental railway economics. In connection with such basic principles of electric railway investments as outlined above, educative efforts cannot be made too carefully or too seriously.

THE UNIVERSITIES AND THE INDUSTRY

An interesting feature of the convention this year was the large number of educators present. This is as it should be. The date at which the convention is held—at the beginning of the college year—makes it very difficult for the active college teacher to be present. Nevertheless, the effort on the part of the association to bring about a closer relation between institutions of learning and the industry was successfully inaugurated this year, and as the advantages of such a connection to both become better understood, we believe there will be a growing co-operation between the two, a co-operation which will not be confined to attendance by the teachers at the annual convention.

The universities and the industry have much to gain from such closer relations. The industry needs the ability for analytical study and research for which years of training have fitted the universities and it needs a sympathetic interest and thorough understanding of its problems on the part of the men who direct the departments of research and mold the minds of our future citizens. The industry also needs the influx into its ranks of the educated men whom the universities are graduating. But the benefits will not be on one side only. Those which the universities can secure from a close touch with the industry are no less great. They comprise opportunities of study and improvement in the laboratory of human industry and reality rather than in the miniature laboratory within the college walls.

The departments in the university with which the closer relations of which we are speaking should be developed are not those purely of engineering. There are many engineering problems to be solved in the electric railway business, but there are other departments of university work with which electric railway companies are rapidly coming into as close, if not closer, touch than with those of engineering. We hope that at the next convention an invitation from the association will be extended not only to the professors in engineering courses as was done this year, but also to those concerned with the science of government and economics. The electric railway problems in this field which must be solved if this country is to progress are acute and of the greatest magnitude, and if the interest of the universities can be enlisted to study these questions thoroughly at first hand a great benefit should be achieved. We hope that the general campaign decided upon at Atlantic City to inculcate right thinking into the body politic will be sufficiently broad to cover this point.

FEATURES OF THE T. & T. CONVENTION

That the Transportation & Traffic Association has behind it a remarkable record of accomplishment is shown in the reports of the various committees. The association has now succeeded in developing, in pracically complete form, standard codes of rules for city and interurban service, the former code having reached its final stage last year, as the only revision submitted at the convention was an amendment to the long-discussed Rule 55. The interurban code, during the past year, has been made consistent in diction throughout as well as made to harmonize with the city code and with that of the American Railway Association in so far as this is possible. This achievement is something of which the association may well be proud, for the difficulties in the way of bringing together the conflicting opinions and varying conditions of hundreds of different railways might easily appear to be an impossible task. Indeed, it was so looked upon by many when the work of preparing the standard codes was undertaken several years ago.

The work of the committee on express and freight traffic has also been exceptionally valuable to the association, not only in pointing out the possibilities of this comparatively new means for increased revenue for electric railways but also by providing, in detail, information as to the means whereby such a business might best be undertaken.

It would seem that the nature of the work of many of the Transportation & Traffic Association's committees is tending more and more toward the custom of having each committee originate, to a large extent, the subjects which are to be considered and discussed before the association in convention. This has applied especially to the work of the committee on transportation employees owing to the fact that the scope of its efforts has been largely extended owing to the safety first movement. It applies also to the committee on fares and transfers and on passenger traffic, both of which have placed before the association discussions on new methods of fare collection and of passenger transportation.

This year the Transportation & Traffic Association has extended its activities to a large extent by a greater development of the joint-committee idea, considering matters in conjunction with the other associations through committees on block signals, on transportation engineering, on block-signal rules and on transportation accounting. The association has even gone one step further this year by holding a session with both the engineering and claims associations to consider the general subject of accident prevention, and it cannot be denied that this marked extension of co-operative action between the various organizations affiliated with the American Electric Railway Association will add materially to the breadth of the information secured.

WHAT THE ACCOUNTANTS ACCOMPLISHED

The sessions of the Accountants' Association at Atlantic City during last week were marked not only by good attendance and the presence of new members but also by the really constructive work accomplished. The committee reports submitted this year were as a whole most valuable contributions to electric railway accounting theory and practice. With the formal adoption of the new Interstate Commerce Commission uniform system of accounts by the association, the classification committee saw the attainment of its longed-for goal. Work still remains to be done, both in rectifying slight errors or omissions that only time can disclose and in striving, with the assistance of the committee representing the association at the National Association of Railway Commissioners convention, to bring about the adoption of the uniform system by all state commissions, but we are confident that the classification committee will continue to display the same combination of assiduous effort, sound judgment, earnest co-operation with regulatory commissions and steadfast devotion to association interests that has characterized it in the past.

The newer committees on freight and express accounting, accounting definitions and education all produced desirable results. While the endeavors of the committee on education have probably had the most tangible outcome, the other two committees laid firm bases for advancement toward the standardization of freight and express accounting and accounting definitions. The securing of uniform accounting definitions was and will be particularly difficult in view of the divergent attitudes of accounting authorities and especially the controlling public service commissions on various accounting practices, but the collating of all commission rulings on both disputed and undisputed points will be valuable as showing the weight of opinion and the amount of work yet to be done to secure absolute uniformity. The most obvious way, of course, to bring about such uniformity is to secure if possible the universal adoption of the Interstate Commerce Commission classification. State commissions now have an opportunity to sacrifice minor differences for the good of accounting practice.

Not by any means in the background, on account of its scope and content, was the report of the committee on engineering-accounting, covering overhead charges, inter-departmental charges and cost accounting. It is the attention given to such subjects that marks the perfection of accounting procedure and scientific management to-day, and the report of the committee is fully deserving of the more extended study that we shall give it later. The recommitment of the report on claims-accounting was largely brought about by minor differences of opinion among the claim agents as to the relative importance of certain accounts, as well as by an alleged lack of mutual exclusiveness among the accounts, but these points can readily be cleared up this year by the proper circularization of the two associations concerned.

Space permits us to comment only briefly on the excellent addresses delivered by Messrs. Wildman, Swift, Fogarty and Sealy, all of whom presented timely, instructive and authoritative discussions on important issues in the electric railway field. It would be improper to leave this résumé, however, without referring to that improvement of association organization contributed by the outgoing officials, through the standardization of committee organization and membership. The definite choice of nine standing committees, with the provision that the majority of their members shall continue over from year to year in order to insure continuity of committee efforts, will be an almost indescribable aid to the new officers. The establishment of a three joint standing-committees will result in greater co-operation and sympathy between the four associations, while the institution of the new standing committee on passenger accounting, with the retention of the committee on freight and express accounting, takes care of a subject of vital importance in all questions relating to an increase of rates, namely, the segregation of expenses between freight, passenger and express business.

POWER MATTERS AT THE CONVENTION

Two eminently serviceable reports on the subjects of power generation and power distribution respectively were presented at Atlantic City. The power end of electric railways is liable to be overshadowed by the more conspicuous and less technical, although no less difficult, transportation, accounting and other parts of the business. The railways must have power to propel their cars, and it is fitting that power problems particularly affecting railways should be carefully considered by the Engineering Association.

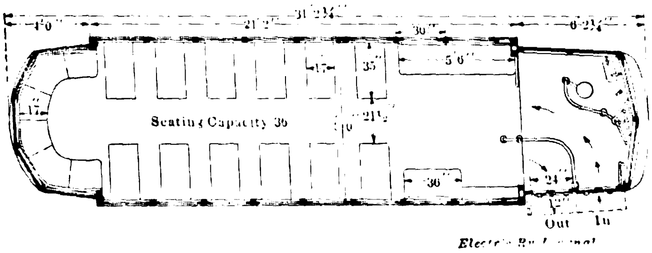
The report on distribution was taken up largely with specifications and revisions thereof. This kind of work is extremely tedious, both in collecting the original data and in phrasing the specifications to insure the getting of the best possible materials without imposing unnecessary hardships upon the manufacturers and thus inflating the cost of the product. There is no way in which an association can exert an influence and achieve prestige more surely than through the maintenance of satisfactory standard specifications. The association's thorough method of handling specification preparation insures good work. Every word in this particular report has been carefully weighed. The retiring chairman of the committee deserves more than verbal thanks for the work which he has done or inspired.

The other report was made up of monographs, and this fact was briefly commented upon in our issue of Oct. 3. We also recently called attention to the diminishing number of convention papers not including in this statement, of course, those individual or joint contributions to committee reports. Now it requires no argument to prove that, for the benefit of its members, the association wants all real contributions to knowledge in its field, but space cannot be found on the programs for them in the form of papers. They can, however, be presented efficiently through committee reports, thus insuring proper correlation of subjects and unity and coherence in their presentation.

Making a Small Company Pay

How the Charlottesville & Albemarle Railway Was Brought from Bankruptcy to Prosperity by the Introduction of Modern Generating and Distributing Equipment, One-Man Prepayment Cars, Park Traffic, Good Headways and Proper Accounting Methods

Charlottesville, Va., is a town of about 12,000 people, situated in the foothills of the Blue Ridge Mountains about 97 miles northwest of Richmond and 114 miles southwest of Washington. It is the county seat of Albemarle County, one of the rich agricultural counties of Virginia noted especially for its apple orchards and for the celebrated Albemarle pippin, of which the greater part of the crop is exported to Europe. The fine climate and beautiful foothill and mountain scenery have attracted many wealthy people from the North and West, who have added largely to the handsome residences in the country surrounding Charlottesville, which district, it is predicted, will some day become the Touraine of America. The city promises to figure in the future as a radiating point for interurban railways extending to prosperous sections of Albemarle and adjoining counties. Steam railroad service is afforded by the Chesapeake & Ohio and the Southern Railways, which here intersect and make the city a railroad center of some importance. Charlottesville has a few silk, woolen, lumber and agricultural manufactories, but it is better known as the home of the University of Virginia, to which some 960 students reported during the college year of 1913-1914. This state university was planned and its older buildings designed by Thomas Jefferson, including the Rotunda, here illustrated, which is a reproduction on a reduced scale of the Pantheon at Rome and which towers the large college library. The university buildings in general recall "Monticello," the home which the great statesman-architect built on one of the near-by mountains.



C. & A. RAILWAY—PLAN OF ONE-MAN NEAR-SIDE CAR

SOURCES OF BUSINESS

In a town of the size and few industries of Charlottesville there would seem to be little chance for the development of a profitable electric lighting, power and railway utility. Further, the lighting department of the Charlottesville & Albemarle Railway has to meet municipal gas competition, while the railway runs over but one route, Main Street, from the Chesapeake & Ohio Railway station, at one end, past the Union station to the university and railway park gounds at the other end. As the original length of route was but 3 miles it is evident that profitable business in this field was out of the question if people were to ride only because they had to do so. In any event, the deficits grew larger and larger from the time that the company was formed in 1903 to its purchase by the present owners in July, 1912. At that time the rehabilitation of the property was entrusted to John L. Livers, now vice-president and general manager. Under his direction the company built an entirely new power plant, changing over from d.c. to a.c. distribution, installed modern prepayment cars with one-man near-side operation to give a frequent and attractive service on an economical basis, converted a money-losing hotel into a set of six cottages and park furnishings, and developed the lighting and power business along popular and more business-like lines. The fruits of the new order began to appear in June, 1914, when the company was earning about twice its fixed charges and when it declared a semi-annual dividend of 3½ per cent on its preferred stock. This was the first dividend in its history. Furthermore, the business, while increasing rapidly, is still well within the saturation possibilities of Charlottesville, so that the owners feel that the outlay of new capital was well worth while. However, it will be clear from the fol-

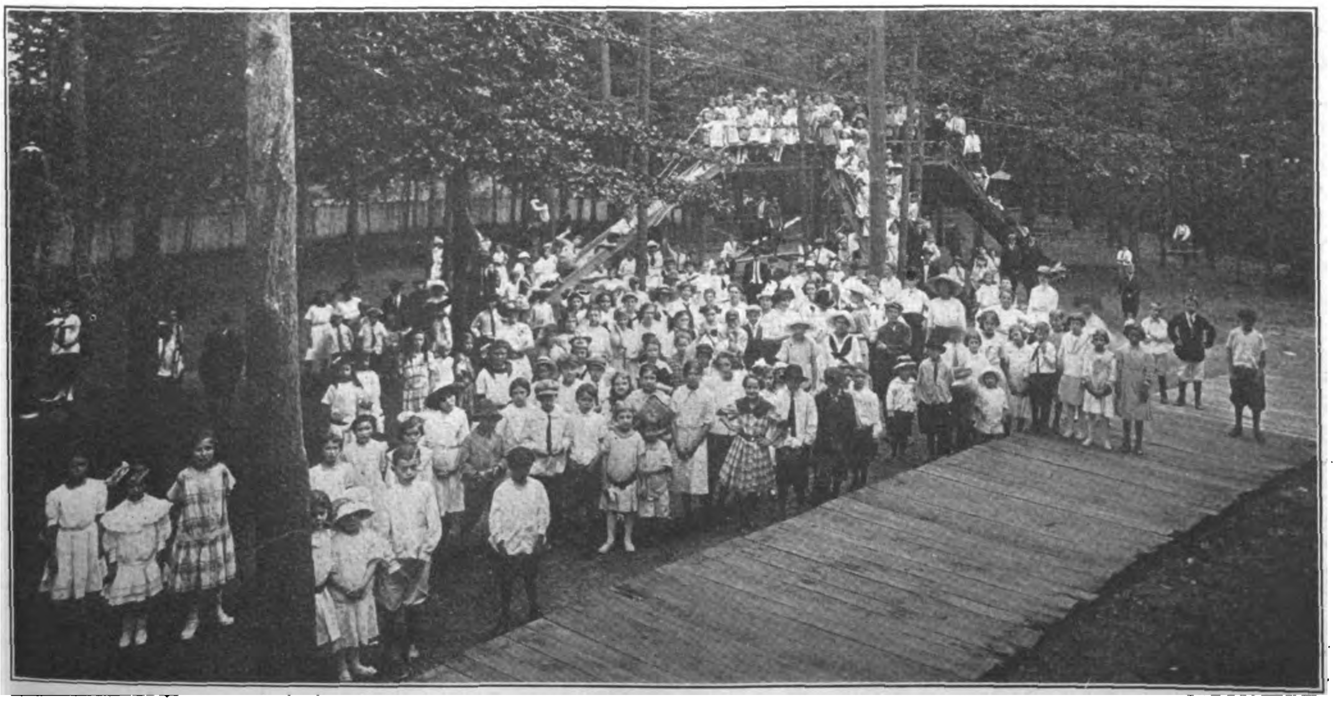
C. & A. RAILWAY—ONE-MAN NEAR-SIDE CAR IN FRONT OF THE ROTUNDA, UNIVERSITY OF VIRGINIA

lowing detailed account of the changes made in each department that the financial success of the company has been due to something more than the influx of new money. In the earlier days, especially, the exercise of mother wit, ingenuity and civic spirit accomplished more than cash alone.

TRACK AND CARS

When the property was taken over in July, 1912, the entire trackage, including sidings, was but 3 miles. As the new management had decided to use one-man single-end cars, changes in the track were necessary at each end of the line. The company was anxious to build a loop at its downtown terminal at the Chesapeake & Ohio station, but it has never been able to get permission from the railway which owns the ground necessary for the loop. The electric railway met the situation by building a cheap turntable by means of which the motorman-conductor readily turns the light cars in use. An extension of ½ mile has been built and a branch extended 1100 ft. directly to the new stadium of the university. The number of sidings on Main Street has also been increased from three to five to enable the railway to give the remarkably short headway of five minutes in a town of 12,000 people. An excellent class of houses is now being erected in the vicinity of the university, the growth in this section being greatly encouraged by the assurance of frequent service to the downtown shopping section.

Two interesting incidents arose in 1912 during the period of track reconstruction and extension. Part of the track at the uptown end was on a badly decayed trestle. This trestle was 200 ft. long and would have cost about $850 to replace. Mr. Livers, however, foresaw that the growth of Charlottesville in this direction would make it far more desirable to fill this section up to grade and to macadamize the roadway alongside. A suggestion to this effect was made to the county commissioner, accompanied by the company's offer to share the expense. Residents along the line were also solicited to favor the improvement and bear a part of the cost. As the result of this missionary work, the road



C. & A. RAILWAY—CHILDREN'S DAY AT FRY'S SPRING, WITH SLIDE IN THE BACKGROUND was macadamized at a cost to the railway of only $100, thus saving $750 compared with rebuilding the trestle, beside securing a safer and permanent construction.

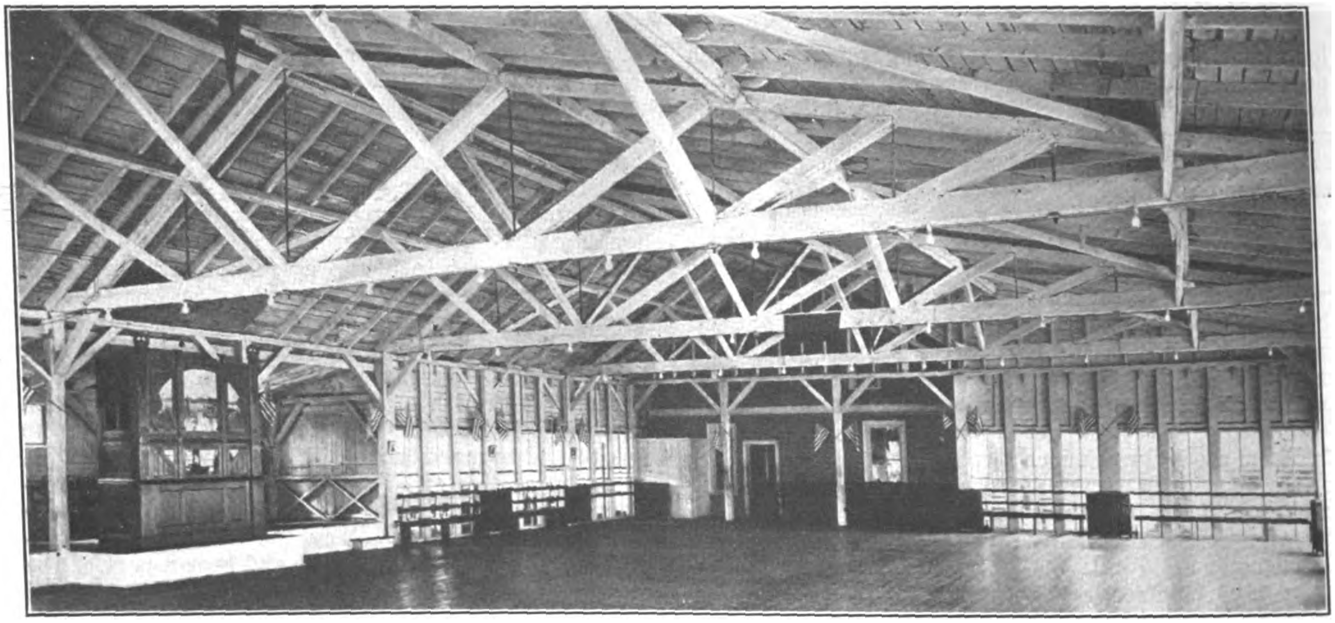
The other incident was the solution of a clearance difficulty. In making the extension at the university end of the line it was found that the old monitor-roof cars would be unable to clear a viaduct of the Chesapeake & Ohio Railway. The electric railway could not afford to raise the viaduct, even if that had been practicable, but avoided the opposite dilemma of lowering the grade of the roadway by the happy expedient of converting from monitor to arch-roof type its original nine open and five closed cars. This change was made by a local carpenter at the rate of $6.75 per car for labor and material, the latter item including sheet-iron ventilators similar in form to those seen on a chimney.

Previous to its purchase of new one-man cars, the company worked wonders with some of the old closed cars by painting the interiors with ordinary bathroom enamel, while the exteriors were painted orange and blue, the colors of the University of Virginia, thus making them more attractive to the students. The cars were also equipped with tungsten lamps. These changes were very inexpensive, but they gave to the cars an air of cleanliness and cheer which met with a hearty approval from the public. However, the cars were of such old-fashioned and heavy build that it would have paid to take them out of regular service almost on the basis of the saving in energy alone. This point is indicated by the fact that the old cars weighed between 24,000 lb. and 30,000 lb., whereas the 31-ft. 2¼-in., one-man near-side car, which averages, say, 5 ft. 2¼ in. more in length, weighs but 18,000 lb. As a single-platform car, with five rows of cross-seats per side and the usual end circular seat and longitudinal seats, the near-side design seats thirty-six passengers compared with an average seating of twenty-four in the longitudinal seat cars. It is true that the usual ride in Charlottesville is short, but for that very reason it was felt that the seating must be attractive and ample to get the business. The safety features of the near-side car constitute another great improvement over the old cars, while the savings of one-man operation are a potent factor in making possible more cars and, consequently, a frequent headway.

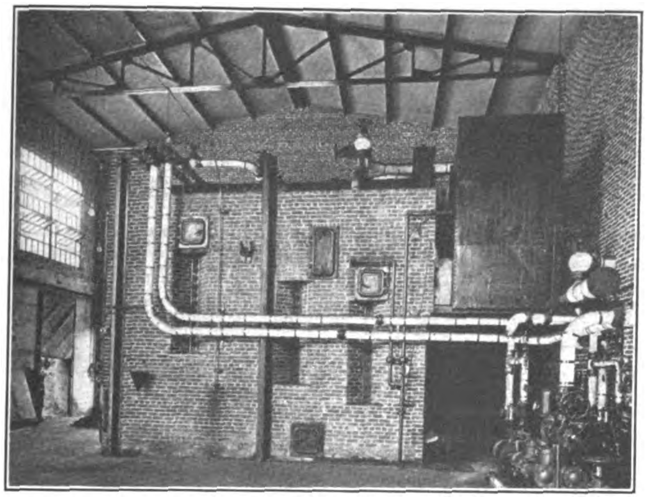
The first order placed with The J. G. Brill Company for near-side cars comprised five. One of these cars was exhibited by the Near-Side Car Company at the October, 1913, convention of the American Electric Railway Association, where its vivid orange, in honor of the University of Virginia attracted many visitors to examine its more substantial qualities. This car proved so popular that the company placed two more in service in June, 1914, making seven in all. All of the cars are of the single-truck type, 31 ft. 2¼ in. over all and 21 ft. 2 in. between the corner posts. An accompanying plan shows the arrangement of seating and of the railings on the 6-ft. 2¼-in. front platform. Owing to a moderate ramp the step heights from the rails to the car floor are but 13 in., 13 in. and 8⅝ in. The only doors used are on one side of the platform, and these are operated by the motorman-conductor in connection with the step. The car body weighs 9500 lb. without equipment. The underframe is made up of steel plates and structural shapes and the body of wood. The interior is in cherry with oxidized trimmings. The trucks are of the Brill 21-E type, with 8-ft. wheelbase. That the operating equipment and minor-furnishings are modern in every particular appears from the use of two GE-200 motors with No. 36-J controller, General Electric air brakes, Consolidated heaters with thermostat control, Consolidated buzzers for the passengers' push-button system, Rico sanitary strap sleeving and tungsten lighting. Air brakes for a single-truck car are uncommon, but they are naturally of great convenience in one-man operation. Tickets are sold six for 25 cents, and these as well as straight 5-cent fares are deposited in New Haven fare boxes.

While the merits of the new cars were quickly appreciated by the public, the railway management made it a point to announce to its patrons that "these cars were built for you." The attitude of a local paper was summarized in its editorial statement concerning the two latest cars, namely, that "They mean one step farther for a larger and better Charlottesville."

All of the cars are equipped with an original station and trip indicator invented by Curtis L. Carter, superintendent of the company. It was devised because some difficulty had been found in keeping the cars on Main Street to such close time that they would pass each



C. & A. RAILWAY—DANCE HALL WITH SELF-PLAYING ORCHESTRAL ORGAN. NOTE ALSO SASH, RADIATORS AND OTHER FIXTURES FROM A DISMANTLED HOTEL

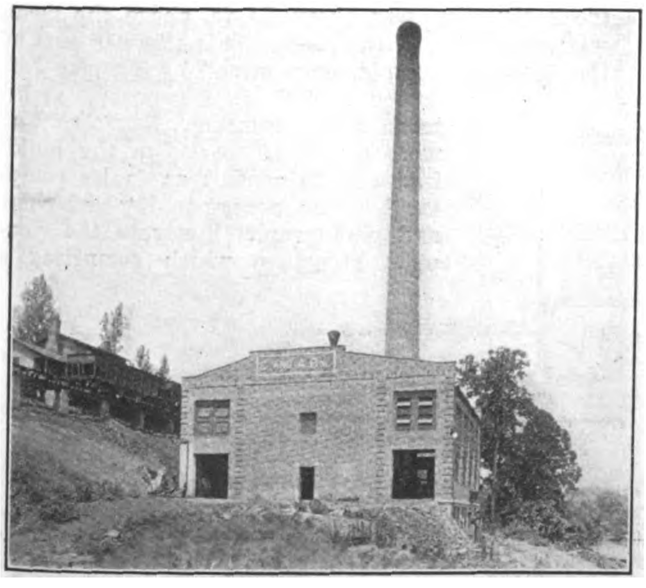


C. & A. RAILWAY—BOILER ROOM SHOWING VERTICAL SLIDING DOOR IN COAL STORAGE AT LEFT

other at any of the five sidings without delay to either car.

Essentially the device consists of an ordinary clock movement, about the size of an alarm clock, arranged for suspension from a hook on the vestibule framing in front of the motorman. The dial consists of a time-table upon which the switches and streets are marked. This dial revolves with the regular clockwise motion so that each switch or station in turn is brought under a pointer fixed on the left side of the clock. The object of the pointer is to designate the point at which the car should be at any given time. Consequently, if the car is at, say, East Fourth Street when the pointer indicates East Fifth Street, the motorman knows that he is one block behind, or if he is at East Sixth Street he knows that he is one block ahead. In this way he can keep on schedule at all times without consulting his watch or a time-table. Arrangements are now being made to place this combination clock and time-table on the market.

The company has, of course, scrapped most of the old closed cars, but one of them has been converted to a work car. No funds were available for an elaborate carhouse, nor was one needed in this climate. Nevertheless, a satisfactory shelter was erected by using old rails for the framing and clothing it with corrugated iron. A reduction from $2.40 to $1.01 per $100 in the insurance rate was also allowed by the underwriters because of a few changes and improvements such as bonding rails, removing wooden floors, installing a line cut-out switch, filling in bad spots, etc. All electrical work is done at home in connection with the lighting and power department.

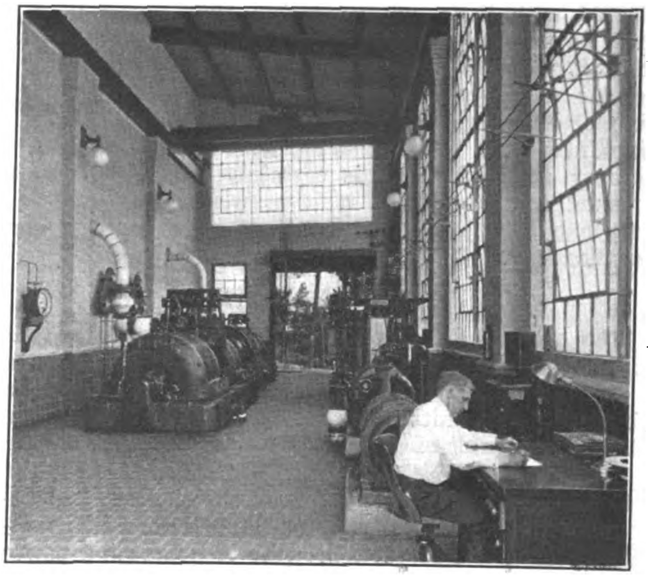


C. & A. RAILWAY—POWER STATION AND CONCRETE TRESTLE AS SEEN FROM THE REAR OF THE STATION

PROFITABLE PARK BUSINESS

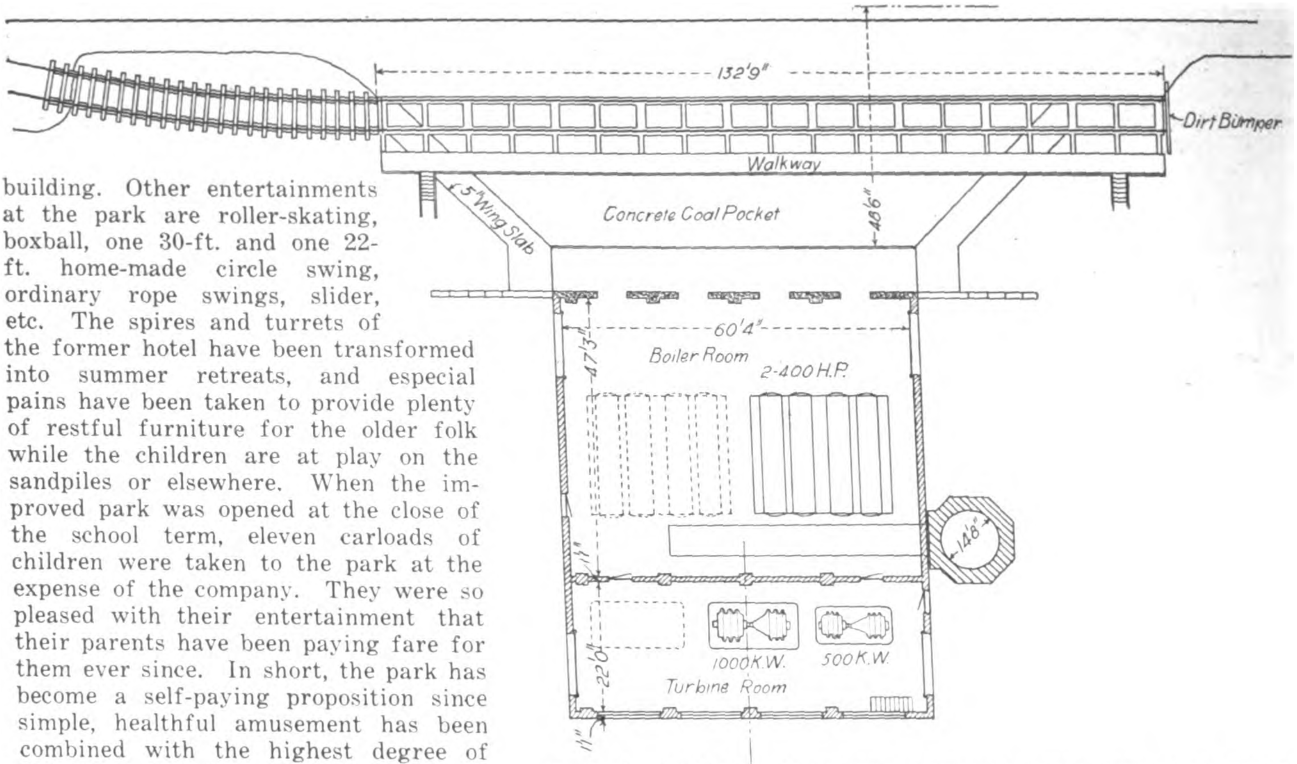
Near the university end of Charlottesville the company owns Jefferson Park, a 13-acre natural playground. This park, of course, depends for patronage only upon the white population of Charlottesville, which does not exceed 8000. Originally the park had little more than a dancing pavilion, its trees and bushes and Fry's spring, a local health source of some note. The water contains sulphur and iron, but it is not suitable for bottling because it discolors rapidly.

In planning to make the park more attractive the company was fortunate in being able to dismantle a large hotel near by. This hotel had proved a financial failure, but as it was comparatively new its salvage value was high. After six cottages had been built from its materials, plenty of timber, glass and other items were left to furnish the park. In the first place the dancing pavilion was glazed completely with windows, which can be raised to make the pavilion as airy as desired or lowered to make it comfortable on chilly nights. A number of the hotel radiators are available for really cold weather, and the toilets, chairs and kitchen equipment are also from the hotel. The pavilion is attractively decorated with national flags and college banners or streamers, in addition to which handsomely framed photographs supplied by the General Electric Company remind visitors of the many domestic applications of electricity.



C. & A. RAILWAY—INTERIOR OF TURBINE ROOM WITH SWING SASH ON THE RIVER SIDE

One of the most important changes in the operation of the dancing pavilion was the substitution of a Welte electrically-played organ for human musicians. Under the old method the cost of the musicians actually exceeded the entire park receipts. Contrariwise, the organ has paid for itself in little more than a season, it has proved entirely satisfactory for dance music, it is ready with a large repertoire at any time, and it never tries to dictate to the taste of the public. In addition to dancing at the pavilion, moving pictures are flashed upon a screen from an operator's booth outside the



C. & A. RAILWAY—PLAN OF POWER STATION AND COAL TRESTLE

building. Other entertainments at the park are roller-skating, boxball, one 30-ft. and one 22-ft. home-made circle swing, ordinary rope swings, slider, etc. The spires and turrets of the former hotel have been transformed into summer retreats, and especial pains have been taken to provide plenty of restful furniture for the older folk while the children are at play on the sandpiles or elsewhere. When the improved park was opened at the close of the school term, eleven carloads of children were taken to the park at the expense of the company. They were so pleased with their entertainment that their parents have been paying fare for them ever since. In short, the park has become a self-paying proposition since simple, healthful amusement has been combined with the highest degree of decency and order. It is certainly an unusual achievement in a town where everyone is within easy reach of open country and woodland.

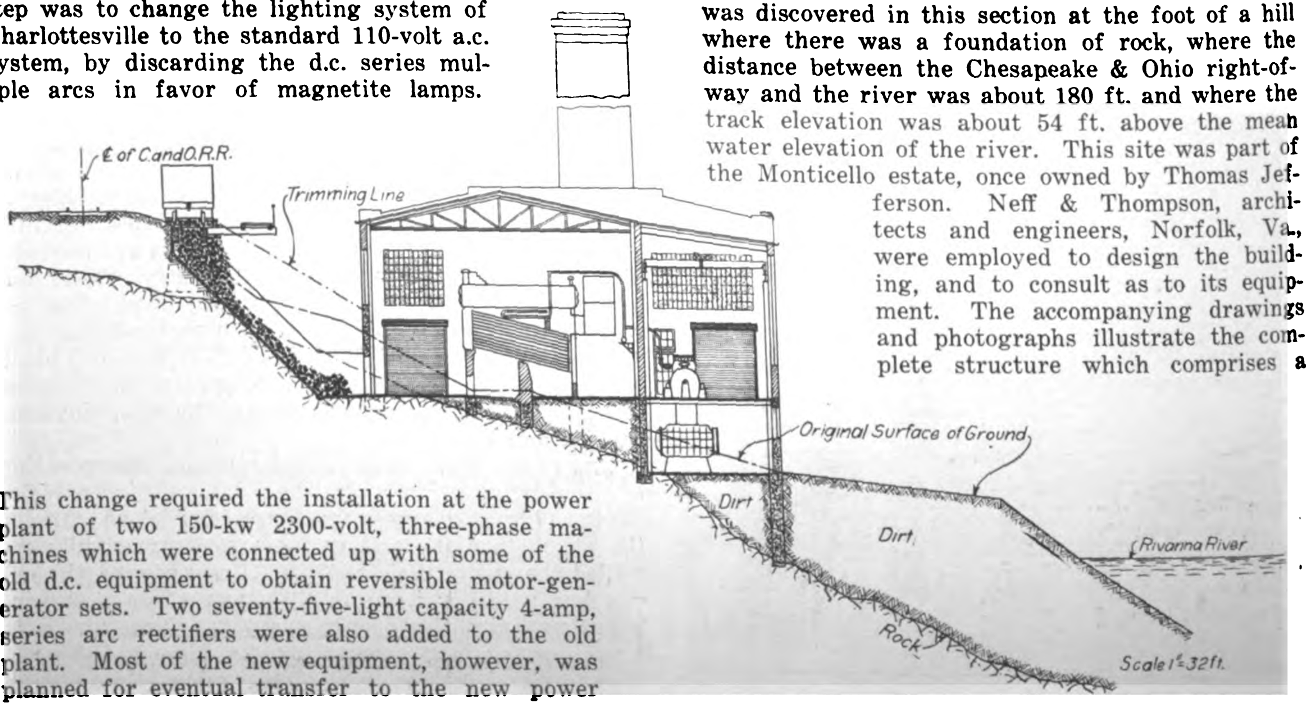
POWER REHABILITATION

The original d.c. power plant of the Charlottesville & Albemarle Railway was in the heart of the city in a location where a cheap water supply could not be obtained. The units consisted of one 100-kw and three 150-kw generators belted to one 300-hp and one 500-hp Corliss engine. With the growth of Charlottesville the 440-volt three-wire d.c. system of distribution had become uneconomical while the machinery itself was practically obsolete. In fact, the cost of generating power was sometimes as high as 8 cents per kw-hr. The first step was to change the lighting system of Charlottesville to the standard 110-volt a.c. system, by discarding the d.c. series multiple arcs in favor of magnetite lamps. This change required the installation at the power plant of two 150-kw 2300-volt, three-phase machines which were connected up with some of the old d.c. equipment to obtain reversible motor-generator sets. Two seventy-five-light capacity 4-amp, series arc rectifiers were also added to the old plant. Most of the new equipment, however, was planned for eventual transfer to the new power plant hereinafter described.

In February, 1913, the company was obliged to order a 500-kw Curtis turbine, owing to a flywheel explosion on the 500-hp Corliss engine. As no condensing equipment was on hand, the company made a surface condenser out of an old boiler. This accident was only one of many power difficulties before the new plant was ready.

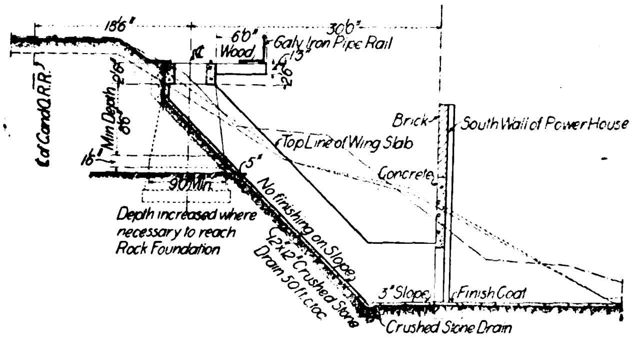
POWER STATION

Before the site for the new plant was selected, a careful study was made of all the surrounding country, and a location was discovered which was admirably suited for the needs of the company. About 2 miles east from the city the tracks of the Chesapeake & Ohio Railway nearly parallel the banks of the Rivanna River. A point was discovered in this section at the foot of a hill where there was a foundation of rock, where the distance between the Chesapeake & Ohio right-of-way and the river was about 180 ft. and where the track elevation was about 54 ft. above the mean water elevation of the river. This site was part of the Monticello estate, once owned by Thomas Jefferson. Neff & Thompson, architects and engineers, Norfolk, Va., were employed to design the building, and to consult as to its equipment. The accompanying drawings and photographs illustrate the complete structure which comprises a

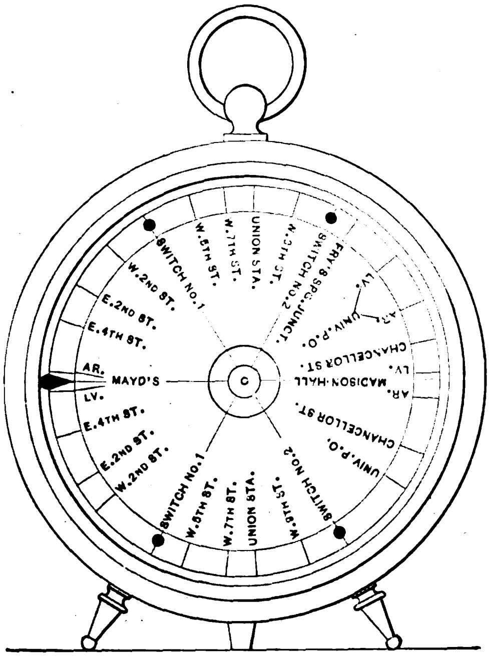


C. & A. RAILWAY—CROSS-SECTION OF POWER STATION, COAL DUMP AND GENERAL LAYOUT turbine room 60 ft. 4 in. x 22 ft. and a boiler room 60 ft. 4 in. x 47 ft.

The entire arrangement is a model of convenience and simplicity. A siding was installed upon a specially designed concrete trestle, the sloping railway embankment was covered with a concrete slab, and at the foot of the embankment the boiler-room floor was located so that coal dumped from the hopper-bottomed cars would by gravity slide down this 1000-ton coal pocket at an angle of 45 deg. into the boiler room directly in front of the hand-fired boilers. The rate of flow into the boiler room is controlled by manually-operated vertical sliding coal doors in the wall between the coal pocket and boiler room. The turbine-room floor was located at the same level as the boiler-room floor, and ehe turbine-room basement in which the surface condensers were installed was obtained with the minimum amount of excavation, the condenser piping being connected directly with the river. All of the foundations of the building were of reinforced and plain concrete, reinforced where subjected to water pressure from the outside during such times as the river is in flood and also in the coal pocket where the south wall of the boiler room acts as a retaining wall for the coal pocket. In other locations plain concrete was used. On these concrete foundations the exterior walls and division walls of hard burned common red brick were constructed, the brickwork being laid up with mortar containing a liberal amount of Portland cement. These walls are bearing walls, that is to say, they contain no built-in columns of any kind. All of the sash are of the Lupton roll-steel type arranged with a liberal number of pivoted sections for ventilation, the various pivoted sections being operated by means of gang operating devices so that all openings on one side of the building are controlled simultaneously from one position. This sash is wire-glazed except that the lowest row is of French clear plate to give the turbine-room attendant a good view of the river conditions. The larger door openings are protected by means of interlocking-slat rolling steel doors, the smaller openings are fitted with metal covered doors and frames. The roof construction consists of structural steel trusses with channel-iron purlins and thin "Ferroinclave" reinforced concrete slab formed by the use of dovetail sheet metal with a 1½-in. layer of concrete on the top and a ⅜-in. coating of plaster on the underside. On top of this concrete slab was placed about 5000 sq. ft. of the H. W. Johns-Manville Company's J-M asbestos three-ply built-up roofing. The brick stack, which is located at the front end of the building, is of the Custodis type, 175 ft. high and with an inside diameter of 7 ft. 6 in. at the top.



C. & A. RAILWAY—DETAIL OF CONCRETE COAL STORAGE



C. & A. RAILWAY—SCHEDULE CLOCK

The inside facing of the turbine-room walls is an impervious pressed brick of buff color. There is also a wainscoting of cherry-red quarry tile with a tile floor, and this finish with the neat tungsten fixtures gives the interior a most agreeable appearance. The concrete floor is reinforced with Kahn bars. Any parts of the machinery can be moved with a hand-power 10-ton Reading crane. The turbine room also contains a high-grade toilet, washroom and shower bath equipment.

The underwriters have given this completed building a rate of 8 cents per $100 of insurance carried. This represents probably the lowest rate which has ever been given a power house in the South, and as a matter of fact is within 1 cent of being the lowest possible rate obtainable upon a power house in the Southern cities under the existing insurance schedule. This result was made possible by the architects and engineers, who, before the building was started, had a thorough and definite understanding with the underwriters concerning their requirements, penalties, etc. The only place in which they departed from the requirements of the underwriters was in connection with structural steel which the insurance companies wanted to have protected throughout with fireproofing. It was found upon investigation, however, that to protect the structural steel members supporting the roof slab in this way would cost more than was justified by the 1 cent in insurance rate which could have been saved in this manner. The company in its old plant paid 24.1 cents per $100 instead of the 8 cents per $100 which it now pays.

While the exact cost of this completed station is not available, the owners assert that the slight increase in the cost of a fireproof building of this character over a building of ordinary construction was amply justified by the saving in insurance alone, although if the saving in insurance was entirely neglected the saving in the cost of repairs would justify this expenditure. Of course, it is also worth much from an operating standpoint to have a power house that will be subjected to a minimum degree to interruptions from fire.

POWER-HOUSE EQUIPMENT

The boiler room contains two 400-hp B. & W. boilers which are operated at a pressure of 175 lb. and 100 deg. Fahr. superheat. Room is provided, however, for a duplicate equipment. The superheated-steam lines are extra heavy pipe with Shawco bell-turned joints and high hub steel flanges, cast-steel fittings and cast-steel body valves. A separate saturated steam connection from each boiler supplies steam to a header for steam to the boiler feed and air pumps, and other auxiliaries. The piping was designed and installed by the Benjamin F. Shaw Company, Wilmington, Del. It comprises a total length of about 700 ft., all covered with 85 per cent J-M magnesia covering.

The condensers for the turbines are of the surface type, manufactured by the Wheeler Condenser & Engineering Company. They maintain a vacuum of approximately 28½ in. to 29 in. of mercury. The condensate is used for boiler feed, supplemented by water from a spring on the property, while circulating water is taken from the river and returned at a point below the plant. One GE water-flow meter and two steam meters are installed to keep an accurate check on the steam-raising equipment. The boiler feed pumps are of Epping-Carpenter make, and the feed-water heaters are of the Stilwell-Bierce open type.

The turbine room now contains the 500-kw 3600-r.p.m. unit which was taken from the old plant. This machine is connected to a 2300-volt, three-phase, sixty-cycle generator. The second Curtis turbo-generator set is of 1000-kw capacity. It is also operated at 3600 r.p.m. and supplies the same kind of current. Foundations have already been provided for a duplicate 1000-kw set. The exciters consist of one 25-kw, 125-volt, d.c. generator, direct-connected to a 3600-r.p.m. non-condensing Curtis turbine. There is also one 17½-kw, 1800-r.p.m. motor-generator set with 125-volt generator, compound-wound and 2200-volt, three-phase, sixty-cycle motor.

The switchboard is of standard General Electric design, the material being of natural black slate panels 1½ in. thick in three sections, 90 in. high, mounted upon pipe framework. The instruments have dull black finish. The panels reading from left to right are as follows:

1—Swinging bracket containing power factor and synchronizing instrument.
1—17½-kw exciter panel
1—25-kw exciter panel
1—500-kw generator panel
1—1000-kw generator panel
2—a.c. feeder panels, capacity each 1250 kva.
1—Tirrill regulator

The current as generated at 2300 volts is carried into Charlottesville over two circuits. The only other wires from the power plant are for a private Bell telephone system which ties in the power station, substation, office and carhouse.

The day load at the present time averages approximately 300 kw and is rapidly increasing. The night load line, which averages about 600 to 700 kw for a short period, is also building up quite rapidly. The efficiency of the new plant as compared with the old one is indicated by the fact that for 175,000 kw-hr. a month it is actually using only four cars of coal compared with fourteen to fifteen cars when a load of only 125,000 kw-hr. a month was carried.

The old plant is still being used for the mercury arc rectifiers and a.c.-d.c. sets, but it is planned to transfer this equipment to a new brick substation and office building on Main Street near the car shelter, so that both cars and machinery may be cared for by only one man.

PROMOTION OF LIGHT, POWER AND RAILWAY BUSINESS

When the property was taken over by the present management, the office of the company was located at the power plant instead of being on the business street of the town. No solicitors were employed, rates were high and inconsistent, and it is reported that considerable money had been lost through improper accounting and unpaid service. One of the first steps was to rent a store located on Main Street, where the public could conveniently do business with the company and see frequently its display of electrical specialties and wiring supplies. The old rates of 18 cents per kw-hr. maximum to 5 cents minimum were reduced to 12 and 4 cents respectively, with a second minimum of 3 cents per kw-hr. for large-motor service. Solicitors who were sent out met with such success that the number of customers was increased from 300 in 1912 to 1006 in June, 1914.

The retail sales of electrical supplies also rose rapidly, as is indicated by the fact that for the year ending June 30, 1913, the company sold $5,000 of tungsten lamps in addition to 300 flatirons, twenty-three vacuum cleaners besides many vibrators, percolators, etc.

The change to 110-volt a.c. distribution also made it possible for residents of Charlottesville to bring such items from other cities without finding them useless on the local circuits. The number of arc lamps, including the city contract, was increased from 106 to 140. In short, in one year, the power and lighting business grew from $18,541 to $36,176.

A detailed study showed 1863 electrical possibilities in all, and of this number the company now has 1006. Only one solicitor is now needed, and six wiremen, with helpers, are constantly employed to wire houses. One of the advertisements which the company uses to call attention to the advantages of electric lighting is a bill file, the front of which is made in the form of an incandescent lamp and bears the words "Is your house wired?"

Among the latest customers of the company is a lumber mill with 135 hp, a woolen mill with 140 hp and a silk mill with 40 hp in motors.

The business-like methods adopted for handling lighting and power accounts have also been applied to the railway service. It is a fact that at least 20,000 deadhead rides were given in the year before the present management took hold. Free service has been eliminated with absolutely no grumbling because the improvement in the service is so evident that no fault-finders can get a hearing from the public. For the year ending July 31, 1913, the railway carried 892,055 passengers. The gross earnings from the railway service are now more than $15,000 per mile of track installed.

The company co-operates wherever possible in all measures brought forward to advance the interests of the community, and has taken a leading part in the Charlottesville Chamber of Commerce. Through personal solicitation the membership of this body was increased from ninety to 308 in one year, and funds were collected to pay for a secretary who would devote all his time to progressive publicity for Charlottesville. As a last word, it may be said that the relations of the company with the public are very pleasant indeed, for the people appreciate the enterprising spirit that has furthered the promotion of Charlottesville's general welfare by giving the town a high-class public utility service.

The present ownership and management of this property comprises the following: President, F. C. Todd, Baltimore, Md., manager Baltimore office, General Electric Company; vice-president and manager, John L. Livers, Charlottesville, Va.; secretary, E. E. Starke, Charlottesville, Va.; treasurer, Norman James, of the N. W. James Lumber Company, Baltimore, Md.; general superintendent, Custis L. Carter, Charlottesville, Va.; R. H. Fife, superintendent of construction, and Geo. H. Smith, in charge of wiring and supply department.

Mooted Principles in Valuation

Abstract of Address Delivered by Hon. Frank W. Stevens, Chairman of Valuation Committees, New York Central Lines, Before A. E. R. A. at Atlantic City—Discussion of Distinctions Between Valuations of Public Utilities for Different Purposes

At the Tuesday afternoon session of the American Electric Railway Association convention at Atlantic City one of the leading addresses was that delivered by Hon. Frank W. Stevens, chairman of valuation committees, New York Central Lines, on the subject of "Mooted Principles in Valuation." An abstract of this address, which on account of its importance was held over until this issue for more extended treatment, is published below:

It is exceedingly extraordinary that valuation should be called a mooted question, yet the fact remains that it is. The valuation of public utilities has been carried on for a considerable number of years in this country, but with very little reference to the foundation principles upon which valuations should be conducted.

OPINIONS ON RETURN ON BONA FIDE INVESTMENT

At a hearing before the interstate commerce committee of the House on Feb. 15, 1912, Commissioner Clements of the Interstate Commerce Commission testified that it was "sound justice and law that, as a basis for constitutional earnings, a fair return on the value of the property means, generally speaking, a fair return on the investment actually made, originally and subsequently." Investment means simply the money that the stockholders have taken out of their pockets or borrowed and put into the business.

The same question was raised before the Senate committee, when Commissioner Meyer said: "But there is an element, and one upon which, if the Interstate Commerce Commission is to make this investigation, you will have to give us some instructions—namely, how to keep property that was originally donated, and what to do with the advance in the value of railway property caused by the development of the community. These questions are directly involved in the question of physical examination." The proposition to which Commissioner Meyer alludes is that the property which was originally donated to the public service corporation was not entitled to any return in the rate whatsoever, and also that appreciation of railway property should not be recognized. This goes back directly to the investment proposition.

The principal witness before the Senate committee on interstate commerce, who was chiefly instrumental in framing the present valuation act, was Prof. John R. Commons, of Wisconsin. At Professor Commons' suggestion, the form of the act was expressly made to allow the Interstate Commerce Commission to pass upon the very questions now being discussed. Professor Commons said:

"The amount of value on which this company is entitled to earn a profit is the amount of its real or reasonable investment, the amount which the owners have taken out of their pockets, and which they might have invested elsewhere under fair competitive conditions and secured themselves a fair competitive return. But if the public has paid a higher rate and that higher rate has gone into the new construction of physical property, that excess in the inventory value of the physical property does not represent a grant on the side of the company against the public but represents a contribution which the public has made to the physical property."

As long ago as 1910 in the advance rate cases before the Interstate Commerce Commission, both in the Western case and in the Eastern case, the commission itself spoke on these subjects. In the Western case Commissioner Lane said:

"Perhaps the closest approximation to a fair standard for the basis upon which to compute the return allowed to public service corporations is that of *bona fide* investment, the sacrifice made by the owners of the property, considering as part of the investment any shortage of returns there may have been in the early years of the enterprise. By thus taking the life history of a road through a number of years, its promoters are entitled to a reasonable return."

This return, however, is expressly limited, for it is provided that no return shall be given on wastefulness, mismanagement or poor judgment, there always being the restriction that no more than the reasonable rate shall be charged. Thus in the same case the commissioner said: "It would appear that one of the problems of the future in railroad regulation is to discover the machinery by which the railroad may justly take to itself an adequate return for the investment made by its stockholders and also share with the community the advantage of the surplus which it creates."

In the Eastern case, Commissioner Prouty made the following remarks:

"The president of the Pennsylvania Railroad testified that since 1887 his company had put into the Pennsylvania lines east of Pittsburgh $262,000,000 from earnings. During all that time this company also paid its stockholders munificent dividends. Now, to whom belongs this $262,000,000, a sum which, according to the statistical report of the Pennsylvania Railroad to this commission for the year ended June 30, 1910, equals nearly two-thirds of the cost of construction of the 2123 miles of railroad owned by the company?

"Should there not be some distinction made between this sum which has accrued from the operation of the property and the amount which has been paid in from other sources? We are not required at this time to express an opinion on this point."

QUESTIONS AT ISSUE

The above statements and extracts from opinions call serious attention to a matter which has many advocates —namely, the opinion, first, that a public service corporation should not be allowed to earn any return upon property originally donated to it; second, that it should not be allowed to earn any return upon property paid for out of earnings, assuming, of course, that during the time when these earnings were accumulated the company was earning a reasonable dividend upon its actual investments; and, third, that the public service corporation should not be allowed to earn any return upon appreciated values, or, as sometimes stated, though unfairly on account of the implied assumption, upon the "unearned increment."

LEGALITY OF RETURN

These questions, of course, may be approached from two points of view: First, is the proposition here indicated correct and proper economically? Second, do such questions constitute the law of the land? On account of the limited time at my disposal, however, I shall confine myself to the legal proposition as to whether or not these elements of value, donated property, property paid for out of earnings, and appreciation of property, are such that under the law of the land we are entitled to have earnings upon them.

COURTS FINAL JUDGE OF REASONABLE RATES

The fixing of rates by legislative authority for corporations which had theretofore been entitled under the law to fix their own rates began in this country in the seventies. Among the first cases upon the question as to whether any such legislative power existed was the Munn case arising in Illinois. The United States Supreme Court in that case, after long argument, held what is now universally recognized, that legislatures (and now their delegated agents, public utility commissions) had that power, subject to the condition that the rate fixed must be a reasonable rate.

This, of course, left the matter very largely up in the air, because the test would be required at once—what is a reasonable rate? And a more important question at the outset was: Who has the final power to determine what is a reasonable rate? The Supreme Court in the first instance declared, practically, that the final power of passing on the reasonableness of the rate was a legislative and not a judicial power. This proposition was repeated in subsequent cases and was always held, with some dissent, which kept growing with changes in the court personnel, until 1889. In this year, in the case of the Chicago, Milwaukee & St. Paul Railway versus the State of Minnesota, the court changed its first view and decided that it did not lie in the power of the legislature of any state, or the Interstate Commerce Commission, or Congress to pass the last word upon the question whether a rate was reasonable or unreasonable, but that it did lie with the courts.

Now, upon what theory? It was held in the above and subsequent cases, that the power of the court in that final question was to be exercised and could be exercised for one purpose only, and that was to prevent a confiscation of property. Until legislative action resulted in a rate so low as to mean confiscation, the courts could not interfere. The case of Reagan versus the Farmers' Loan & Trust Company is a very celebrated case on this point. In this case the court said that "While it is not the province of the courts to enter upon the merely administrative duty of framing a tariff of rates for carriage, it is within the scope of judicial power and a part of judicial duty to restrain anything which, in the form of regulation of rates, operates to deny to the owners of property invested in the business of transportation that equal protection which is the constitutional right of all owners of other property."

Further citations are unnecessary to show the functions of the courts with reference to rate-making. The courts have no power to make any rate. They have no power within certain limits to interfere with any rate that is made by a public service commission or by a legislature. They have the power, however, when the rate reaches such a point as to be confiscatory in its practical working, to interfere, because property is protected against such assaults. The great and important question in every rate case that comes before the courts, therefore, is this: What is the property of the corporation? Whatever this property may be, as it is recognized by law, it must be protected by the courts.

The case, then, practically comes down to this: Are items which are in the nature of property—that is, property which has been donated, or which has been paid for out of earnings, no matter whether the returns were excessive or not, or property which has increased in value or appreciated—are those elements of property in the hands of the corporation? If they are, they must be protected against confiscation, the same as any other property. If they are not, then another question arises.

FAIR VALUE OF PROPERTY

The first case in which the question came before the Supreme Court as to the standard to be adopted in determining the reasonableness of a rate, was Smythe versus Ames. At that time all sorts of theories were propounded as to the basis upon which a rate was to be judged. It was argued on behalf of the state that if the property was allowed to earn anything above operating expenses and taxes, the courts could not interfere, and that the measure or the amount of the return was wholly a matter of local state policy. It was also argued by the state that, if this previous contention were not allowed, the company should only be granted a reasonable return not exceeding the rate of interest, upon the reproductive cost of the property. The railroads contended, however, that they were entitled to earn not only the operating expenses and taxes, but also interest upon their bonded indebtedness and a dividend upon the amount of stock outstanding. There were the two poles. The court said that neither of the contending parties were right, and that the basis for the calculation of rates was the fair value of the property.

IGNORANCE AS TO "VALUE"

But now we come to the question which in one sense is amusing and in another sense deplorable. During the seven years when I have been personally engaged in the investigation and consideration of this question, I have scarcely ever been able to find out what anybody thought of the term "value." Since my connection with practical operations under the recent valuation act, hundreds of men have professed to me to be entirely ignorant of what was meant by "value." Such a condition, after the organization of business for thousands of years upon a property basis, is a source of astonishment.

If the value of the property is to be protected, the question must arise how theories such as those laid down by Professor Commons and Commissioner Clements can work. They seem to regard it to be a self-evident proposition that the Supreme Court can change the definitions of value to include or exclude classes of property. This may seem to be an extraordinary statement, but it is not made without proof.

PROFESSOR COMMONS' OPINION

Professor Commons, who is an able man and a profound student, but all of whose statements I do not indorse, says:

"The Supreme Court has really been working out a theory of value in the last forty years, since the Munn case, and has very materially recast its old conception of what constitutes value. The fundamental basis of the court's contention is not market, competitive or actual value, but rather a fair, reasonable or just value. The court recast its theory of value in rate-making cases because it perceived that in setting up a value for the property it created substantially a creditor and debtor relationship, the owners of the property being in the nature of creditors and the public in the nature of debtors for something devoted to their service.

"From 1889, the time of the Chicago & Milwaukee case, down to the present time, the latest cases being the Consolidated Gas case in New York, the Knoxville Water case and possibly one or two more recent cases, the court has been making a transition. It has been shifting its ground as to what is value or valuation, or the amount of value for rate-making purposes. The valuation bill should provide for the original cost to date, in order that the court may have before it the facts, and the amount of differences involved in the different methods of valuation. The securing of original cost and present value would make it possible for the court to consider whether a railroad is entitled to appreciation in its land values, equivalent to the appreciation which private owners adjoining them have enjoyed. My own idea is that if the case were properly presented to the court, the court would adhere to the idea of reasonableness throughout, and would recognize that for rate-fixing purposes this property, being devoted to a public use, was entitled to a return on the actual reasonable investment cost of the property only."

PRESENT PROBLEM OF VALUATION

A very serious question confronts all owners of public service property at the present time. It is being gradually worked out through the valuation act whether or not there can be two kinds of value attached to the same article of property; a value for taxation or a value for sale and another value for rate-making purposes, the last value being one which would exclude the three classes of property previously mentioned as well as others. The only protection which carriers have for their property lies in the definition of the word "value." If theorists, if commissions, if legislatures, if courts can make a definition of "value" to fit the case, then it is just as possible for the Supreme Court or any other court to confiscate utility property as it is possible for a commission or a legislature to do so, and if by changing the definition of the word "value" they can exclude donated property, as Professor Commons seems to think they can, or property paid for by earnings, or appreciation of property, they can confiscate that part of the property by denying any return upon it, for such a procedure is nothing more nor less than confiscation.

MEANING OF VALUE

The first mooted question in valuation, therefore, is: "What is value?" A definition for this cannot be manufactured by the individual any more than by the courts. It is embodied in the language. "Value, in exchange, expresses nothing but a ratio, and the term should not be used in any other sense." Value, in the sense that we are using it, is always expressed in terms of money. What determines this ratio? Nothing more or less than the mental condition. Scores of definitions all run to the same proposition, but in the discussion of this question, inasmuch as the Supreme Court of the United States has the final word upon all these subjects, its opinion is most valuable as to what constitutes value.

From a collection of eight cases before the Supreme Court on the subject of rate making, there has been prepared the following summary:

1. There is not an intimation in any one of the cases that the court is using the term "value" in a sense different to that given to it in condemnation and taxation cases.
2. It has declined to hold that the cost is the value of the property, although consistently holding that it is an element which must be considered in fixing value.
3. It has decided that when property or rights are owned in fact, it is immaterial whether the owner paid anything for them or not. Their value must be respected in fixing the rate.
4. It has decided that in ascertaining the present value it is not limited to the amount of the actual investment; that the making of a just return for the use of property involves the recognition of appreciation in value.
5. It has declined to hold that cost of reproduction is necessarily the value of property.
6. It has held that cost of reproduction is one way or method of ascertaining value. It does not follow, however, that any article may be worth the cost of reproduction or that obsolete property which must be thrown out of use is not worth the cost of reproduction.
7. It has held that a variety of matters are to be considered in fixing value.
8. It has decided that the ascertaining of the matter of value is the exercise of a reasonable judgment having as its basis the proper consideration of all relevent facts, which, of course, is the very element of value in exchange.

RECENT DECISIONS

In the Minnesoa rate cases decided last year, it was pressed upon the court in argument that where a right-of-way has been donated free of cost it should not be included in the aggregate amount upon which to base a return; that lands secured under the right of eminent domain should never be valued at more than the original cost, and that lands procured or purchased from earnings should not be included in the value of the property. The court, however, used this language in reply:

"It is clear that in ascertaining the present value we are not limited to the consideration of the amount of the actual investment, as the company may not be protected in its actual investment if the value of its property be plainly less; so the making of a just return for the use of the property involves the recognition of its fair value if it be more than its cost."

Hence, if the court adheres to principle and its own declarations, the appreciation of property must be recognized as a part of the value. In the most recent case which has come before the Supreme Court, San Joaquin County versus Stanislaus County, 233 U. S. 454, the court held expressly that whether the water rights in question cost the company anything or not they owned them. They were property, and the company was entitled to a fair return upon them. This, then, disposes entirely of the question about donated property.

CONCLUSION

The answer to the question stated at the beginning is this: There cannot be, in principle, two kinds of value, for value is simply a relation between the article valued and money, and there cannot be two relations of the same thing to money. The courts have, in taxation and chiefly in condemnation cases, laid down certain rules regarding property, and property which is donated, acquired from earnings or appreciated, must be recognized as part of the total value. If they are not recognized in rate-making cases, those elements of value are certainly confiscated. Certain well-meaning gentlemen who entertain a view of the economic side of the question far different from what I do maintain that the courts have tried to do this. I have tried to show that the courts have done nothing of the kind. They maintain that the courts can do it. I maintain that the courts cannot do it, because as soon as they do, in a case where they have jurisdiction solely for the purpose of protecting property against confiscation, they thus put a definition to value other than that which they set in condemnation cases, and actually confiscate that part of the property which is not recognized by the new definition.

The Hagerstown & Frederick Railway recently adopted the plan of distributing as souvenirs to the patrons of Braddock Heights Park, Md., a large number of hatpins, the heads of which are buttons, similar to those worn by the trainmen of this line. The design, which was originated by S. H. Bennett, auditor of the company, is very attractive, bearing the words "Heart of Maryland Route." These souvenirs, while inexpensive, proved good drawing-cards at the park, and the demand for them exceeded the supply.

Proceedings of Friday's Session of the Engineering Association Meeting

The Concluding Session of the American Electric Railway Engineering Association was Mainly Occupied with Discussion of Way Matters—L. P. Crecelius was Elected President of the Association

The final session of the Engineering Association opened Friday morning with President Hanna presiding and a representative number of engineers in attendance. The first order of business was the report of the committee on way matters which was presented by Mr. Kimball.

FOUNDATIONS IN PAVED STREETS

R. C. Cram, Brooklyn, N. Y., in opening the discussion of the question of the proper foundations for track in paved streets, emphasized the fact that there were practically only five types of track construction in general use in this country, the sixth type shown in the illustrations accompanying the report being comparatively new. While the committee did not take into consideration all the minor variations in the different designs obtained in response to requests for data, the four types recommended are representative of those followed with more or less success. The crux of the track situation is how much money can railways afford to spend. There are advocates of all types, but the problem resolves itself into one of the most economical designs to fit the service given.

C. R. Harte, New Haven, discussed loads on soil particularly. He brought out the fact that there was little or no information upon which accurate calculations could be made since different soils act differently under varying conditions. In a good many instances the calculated bearing power of the soil is exceeded without serious results. Unquestionably confined soils have a greater bearing power than the same soils unconfined. When the problem is one of improving the bearing qualities of soil, undoubtedly drainage offers the best method while it is possible to obtain fairly good results with a filler or dryer.

Geo. L. Fowler, New York, referred to the information in the reports regarding the results of deflectometer tests conducted by the Chicago Board of Supervising Engineers, particularly referring to the fact that this test did not indicate that the rail raised the load. He also stated that the actual stresses in track were an unknown quantity and practically no records were available. The distribution of the loads over the subgrades largely depends on the quality of material used for ballast. He also made several references to some steam railroad experiments conducted to determine track stresses.

In explanation of the results of the deflectometer tests it was stated that this track was on 9-in. 129-lb. girder rail laid on concrete foundations. Consequently, it was more or less rigid and wave motion was eliminated. C. H. Clark, Cleveland, next replied to Mr. Fowler's theoretical conclusions regarding track stresses by stating that steam railroad traffic conditions did not apply to street railways in paved streets. Street railway traffic is slow-moving, consequently the resulting stresses were not comparable. Pavement maintenance is the most important factor entering into track construction in paved streets. Consequently the most rigid construction produced the best results. President Hanna qualified Mr. Clark's statement, however, by stating that it was impossible to make track absolutely rigid.

E. M. T. Ryder, Third Avenue Railway, New York, suggested that the use of a 7-ft. tie instead of the 8-ft. tie shown in the standard designs aided in reducing the track allowance and this turn resulted in lower construction and maintenance costs. In reply to this suggestion, Mr. Cram stated that the committee's idea in recommending a 6-in. x 8-in. x 8-ft. tie was to furnish a fixed bearing area. So long as the bearing area was maintained the tie lengths and widths could be varied to suit any engineer's ideas.

T. K. Bell, Ardmore, Pa., stated that street railway traffic conditions were not similar to steam railroads, consequently street railway track studies must be made along independent lines. In the past the concrete-beam track construction was popular, but the experience of those using it indicated that it was not good practice—in fact, in many instances it accounted for new difficulties such as rail corrugation. Mr. Bell also referred to foreign practice in making track construction more flexible, calling particular attention to the use of a bitumen layer beneath the rail to reduce noise and provide a more elastic track foundation.

C. H. Hile, Boston, stated that in his experience the present tendency was toward more flexible types of track construction. The element of noise is becoming of considerable importance in a large number of large cities and flexibility seems to offer the solution. In fact, he stated that the question was now up in Boston and a committee had been appointed to make a thorough study of the subject.

Mr. Dodge said that his company was using the concrete-trench type of track foundation with considerable success. It had adopted wood block for pavement because of its improved wearing qualities and noise reducing characteristics.

At this point in the discussion President Hanna suggested that a motion would be in order to approve the recommendation of the way committee or those of the standards committee. After the motion had been put and seconded, Mr. Schreiber stated that it was the standard committee's belief that it would be unwise for the association to adopt these designs as recommended practice, because of the reasons set down in the standards committee report, since some of the designs did not represent the best modern practice. In order that there would be no misunderstanding of the standards committee's action, it was stated that its purpose was to accept the designs as a whole or recommend that they be turned back for further consideration if it disagreed with some of the details. President Hanna stated that he believed that these designs represented the best types in general use to-day and should be so considered.

In explanation of some points raised in the discussion, Mr. Cram stated that the committee was undecided as to the correct assumptions for the soil bearing qualities. Improper drainage unquestionably reduces bearing power of soils, consequently elimination of moisture is of prime importance. Another phase of the subject which should receive consideration was the character of traffic and the fact that it could not be diverted entirely during the construction period. In practically every city it is necessary to build track under service. Consequently the type of construction adopted must permit this practice. Regarding the use of solid concrete construction, Mr. Cram stated that some of the largest companies in the country had adopted it as standard. It had to be included as a recommended design. The European practice in constructing tracks in paved streets offered a number of features well worthy of careful consideration. In closing he stated that the track chapter in the 1913 convention issue of the ELECTRIC RAILWAY JOURNAL had served as the basis for the early stages of the committee's work.

The report of the committee as to track foundations in paved streets was referred back in accordance with the recommendations of the standards committee.

T-RAIL IN PAVED STREETS

T-rail in paved streets, the second subject considered by the way committee, was presented by Mr. Graves and discussed by Messrs. Clark, Wilson, Cram and Bell. It brought out the fact that those using T-rail did not believe that it was limited to any traffic conditions excepting special work where it was undesirable from a pavement maintenance standpoint. It was also stated that in many cities its use or its nonuse was attributed to the action of city authorities who specified the rail section to use. A recommendation of considerable importance in favor of the use of T-rail was its tendency to clear the track for vehicular traffic. The report of this sub-committee was received as information.

W. F. Graves, Montreal, suggested that it might be well to recommend to way engineers that comparative records be kept to show the cost of maintaining paving with girder and T-rail construction respectively.

Mr. Hurd, Universal Portland Cement Company, said that an investigation had recently been made in several Western states covering 20 miles of track with concrete paving. He highly favored such construction. As evidence of the complete bond thereby maintained between the rail and pavement, he mentioned the simultaneous breakage of a 7-in. welded girder rail and the cracking of the adjacent paving at Fond du Lac, Wis.

In conclusion Mr. Cram stated that the specifications for concrete pavement distributed at the meeting by Mr. Hurd might give the impression that they had been issued or approved by the committee on way matters. This was not so. The committee had not mentioned any pavement whatsoever. Therefore, this was simply a suggested unofficial specification for paving to go with the committee's proposed type D construction.

OTHER MATTERS

The next order of business was the report on heavy electric traction, which was presented by the chairman, E. R. Hill. The report was duly accepted.

C. R. Harte then presented the report of the committee on resolutions in which thanks were extended to the president, the other officers and the committees for the excellent work they had done during the year. Thanks were also extended to the Manufacturers' Association for its splendid exhibits and assistance to the committees. Mr. Harte then presented a resolution that the executive committee be requested to consider the appointment of a necrology committee to prepare memoirs of members upon their death. The report and motion were duly accepted.

The report of the committee on nominations was then presented by Martin Schreiber as follows: President, L. P. Crecelius, electrical engineer, Cleveland Railway; first vice-president, John Lindall, superintendent of rolling stock and shops, Boston Elevated Railway; second vice-president, B. F. Wood, chief engineer, United Gas & Engineering Company; third vice-president, F. R. Phillips, superintendent of equipment, Pittsburgh Railways; secretary and treasurer, E. B. Burritt. Executive committee: J. P. Barnes, general manager, Syracuse & Suburban Railroad; G. W. Palmer, Jr., electrical engineer, Bay State Street Railway; H. F. Merker, engineer maintenance of way, East St. Louis & Suburban Railway; W. G. Gove, superintendent of equipment, Brooklyn Rapid Transit System. The secretary was instructed to cast one ballot, and the gentlemen named were duly elected.

Retiring President Hanna expressed his thanks to the members for their cordial co-operation that he had enjoyed during his administration, and also expressed his thanks for the assistance given by Messrs. Burritt and Stocks at Association headquarters. President-elect Crecelius was then inducted to the chair. Mr. Crecelius thanked the members for his election saying that the honor was one that he greatly cherished. On motion the session was then adjourned.

ATTENDANCE AT THE CONVENTION

Up to Thursday night 2450 persons had registered at the associations' headquarters. This is a reduction of 20 per cent from last year's registration of 3085. There were 1400 railway men, 464 or 25 per cent fewer than last year; and 1050 supply men, 171 or 14 per cent fewer.

CORNELL ELECTRIC RAILWAY REUNION LUNCHEON

Following the precedent established last year the Cornell men in attendance at the Atlantic City convention held a get-together luncheon. At 12:30 on Thursday thirty or more railway and supply men lunched together informally at the Marlborough-Blenheim. Before lunch was served each man rose in turn and stated his name, class and present occupation. Ernest Gonzenbach, general manager Empire United Railways, and E. J. Dickson, vice-president International Railway, attended as guests. A permanent reunion committee was appointed as follows: Fred. L. Wright, vice-president Wm. Wharton, Jr., Inc., Philadelphia, Pa., chairman; W. K. Archbold, president Archbold-Brady Company, Syracuse, N. Y.; C. H. Clark, engineer maintenance of way Cleveland Railways, Cleveland, Ohio; T. M. Farmer, Jr., vice-president Consolidated Car Heating Company, New York; H. H. Norris, associate editor ELECTRIC RAILWAY JOURNAL, New York, and Lee H. Parker, Stone & Webster Engineering Corporation, Boston, Mass. Mr. Wright desires the names of all Cornellians engaged in electric railway work.

A meeting of secretaries of technical societies has been called for October 31 at the United Engineering Societies Building in New York to consider the formation of a Society of Technical Associations' Secretaries. This is the outgrowth of a movement which has been under development for some time as a result of the increasing necessity for co-operation in society management. The number of technical societies is now so great that some simple method of preventing conflict of dates of meetings, scope and plan of work, etc., seems to be imperatively needed. The objects of the proposed association will not be definitely defined but they are comprehended in a suggested phrase as "the development and solution of problems of mutual interest to the service of its members." The call for the meeting is signed by the secretaries of the following societies: American Institute of Electrical Engineers, American Society for Testing Materials, American Society of Mechanical Engineers and American Institute of Mining Engineers, and American Institute of Chemical Engineers.

Reports Presented at Concluding Session of the Engineering Association

The Committee on Way Matters Reported Extensive Data Based on a Comprehensive Canvass of the Association Membership—The Committee on Heavy Electric Traction Presented a Brief Report—Abstracts of the Reports are Given Below

The report of the committee on way matters of the Engineering Association, presented yesterday, covered: Proper foundation for tracks in paved streets; use of T-rails in paved streets; pavement for use in connection with girder and high T-rails, and alloyed steel rails. The report showed that the basic principles followed in the study of track foundations in paved streets were permanency and the features which influenced it. Permanency is of prime importance to electric railway tracks in paved streets, where, as a rule, the types of pavements found are costly, and both the railway and street traffic are heavy, making repairs difficult and expensive. After a careful study of all the factors influencing the design, the committee concluded that the question of proper foundations for track in paved streets required a most careful study of the soil in the street with respect to its bearing value.

Dependable data regarding the bearing values of various surface soils were somewhat meager, but sufficient information was found to allow the committee to recommend designs of foundation construction for adoption. The bearing powers of the soils, shown in the following table, were taken into consideration:

Material	Safe Load in Tons Per Square Foot
Quicksands and wet soils	0.1 to 1.0
Dry earth according to depth below surface	1.0 to 3.0
Moderately dry clay, confined	2.0 to 4.0
Dry, stiff clay	4.0 to 6.0
Sand, confined	2.0 to 6.0
Sand, compact and cemented	4.0 to 8.0
Gravel, cemented	8.0 to 12.0
Rock	25.0 to 200.0

As a result of a study of the track-drainage problem, the committee found that much soil which was considered unfit for roadbed without some form of concrete foundation may be rendered serviceable by the installation of a suitable subsoil drainage system. In this connection it was also concluded that heavy clay soil which retains moisture for long periods required subsoil drains regardless of the type of foundation used. To give an idea of the percentage of moisture retained by certain soils which would prove of value in determining what drainage arrangements were necessary, the following figures were given: Pure clay, 70 per cent; clay loam, 50 per cent; loamy soil, 40 per cent; sand, 25 per cent.

It was also found that the character of the foundation was closely related to the question of electrolysis, being to a certain extent a determining factor of the leakage of stray currents. A well-drained rock or concrete roadbed may, in general, be expected to offer much higher resistance to leakage current than one in which a large amount of moisture is retained. Another factor in obtaining good foundation drainage is the installation of surface drains and a pavement which will prevent the infiltration of surface water.

Information gathered from the data sheet tended to show that the practice of rolling the subgrade and ballast was increasing, and the committee recommended that rolling should be done wherever practicable under working conditions, if warranted by the kind and condition of the subsoil. Rolling is especially recommended where the street is known to be on made ground, or where there has been much disturbance of subgrade due to foreign subsurface constructions and cross trenches. Where it is impracticable to roll, the subgrade should at least be thoroughly rammed so as to eliminate soft spots, and the ballast thoroughly tamped by hand or by operating loaded cars over the track, the tamping being continued until there is no movement observed under load. In some instances, a subballast of cinders, placed under the crushed stone or gravel ballast, may be used to advantage. This is particularly true where it is desired to increase the depth of the ballast without greatly increasing the cost of ballasting materials.

In order to eliminate the misunderstanding as to the meaning of the term "permanent track construction," the committee made the following explanation: A track may be called permanent when it is built to the established line and grade in a street, wherein all customary foreign sub-surface structures are in place and the permanent pavement of the street has been installed, or will be constructed, immediately following the track construction. A permanent track also is one designed with the object of securing the minimum maintenance cost and the maximum life from the several materials involved when subjected to mechanical wear, action of the elements and harmful disturbances not under control.

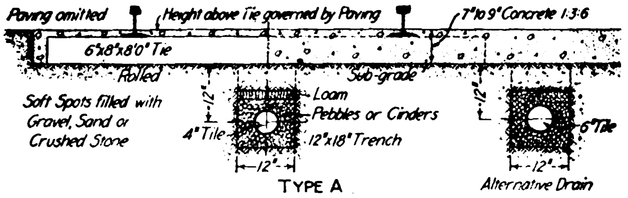
The principal items to be considered in the design of track structures in paved streets were stated to be as follows: Character, bearing power and drainage of sub-soil; loads to be carried; form of sub-structure necessary to distribute the loads over the sub-soils; form of superstructure to be carried by the sub-structure; the character of the street improvements with respect to line, grade, sub-surface structures and paving, and the traffic conditions under which the work is to be executed.

Information gained from the data sheets indicates that only 20 per cent of the eighty roads reporting on the subject of ballast use concrete ballast construction. While this may be somewhat misleading since it is not on a mileage basis, it is an indication of the preference. When it is also considered that some of the largest properties are abandoning concrete construction in favor of either stone ballast or the more resilient concrete sub-ballast construction, it appears that current practice is not generally in favor of solid concrete.

Two general conditions usually are confronted in constructing track in streets, the one where most of the improvements are yet to be made, such as in new extensions through recently developed territory, and the other where all the expected improvements have been made or will be completed within a very short time. Under the first condition it is not generally advisable to install a standard permanent type of construction, but a temporary type which can be removed before a full life is reached should be used. Where the improvements are in, it is desirable to install a standard construction suited to the conditions obtaining, and such construction should preferably be entirely new in order to obtain a maximum life from all its component parts.

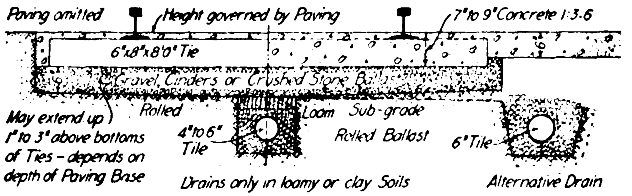
In order to obtain uniformity in designing methods, the committee adopted a standard track loading to be used. It is believed that the load produced by a 50-ton car supported on eight wheels with 25-ft. truck centers, and 5-ft. wheelbase should be adopted. In considering soils a load of 1.5 to 1.75 tons per square foot should be used, and the soil should be assisted in performing its whole duty by adequate drains.

As a result of its study of all the factors which might influence the various designs of track foundations in paved streets, the committee submitted four types of foundation construction for adoption as recommended designs. These are shown in the accompanying illustrations. Sub-soil conditions largely govern the selection of any of these four types. It was inferred, however, from the information at hand that the soil generally found in city streets was in the original state, or if it has been in place for many years, afforded sufficient strength in the sub-grade to sustain the average loading, provided the loads are distributed through a moderate amount of crushed stone, gravel, or even cinder ballast.



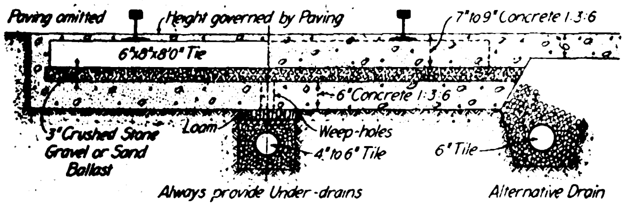
Paving omitted
Height above Tie governed by Paving
7" to 9" Concrete 1:3:6
6"x8"x8'0" Tie
Rolled
Sub-grade
Soft Spots filled with Gravel, Sand or Crushed Stone
12"
Loam
Pebbles or Cinders
4" Tile
12"x18" Trench
12"
12"
6" Tile
12"
Alternative Drain

TYPE A
For Gravel, Sand and sandy loam Soils - Moderate Traffic and Cars up to 25 Tons
Provide Surface Drains



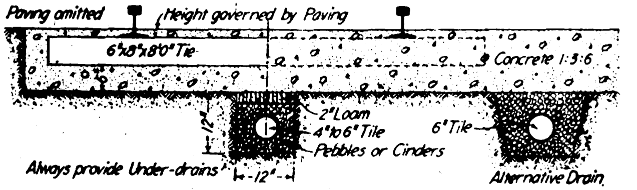
Paving omitted
Height governed by Paving
7" to 9" Concrete 1:3:6
6"x8"x8'0" Tie
Gravel, Cinders or Crushed Stone Ballast
May extend up 1" to 3" above bottoms of Ties - depends on depth of Paving Base
Rolled
4" to 6" Tile
Loam
Sub-grade
Rolled Ballast
6" Tile
Drains only in loamy or clay Soils
Alternative Drain

TYPE B
For most Soils except very heavy Clays - Heavy Traffic and heaviest Cars up to 35 Tons
Provide Surface Drains



Paving omitted
Height governed by Paving
7" to 9" Concrete 1:3:6
6"x8"x8'0" Tie
6" Concrete 1:3:6
3" Crushed Stone Gravel or Sand Ballast
Loam
Weep-holes
4" to 6" Tile
6" Tile
Always provide Under-drains
Alternative Drain

TYPE C
For heavy water-retaining Soils and other uncertain made Ground - Heaviest Traffic and Cars
Provide Surface Drains



Paving omitted
Height governed by Paving
6"x8"x8'0" Tie
Concrete 1:3:6
2" Loam
4" to 6" Tile
6" Tile
Pebbles or Cinders
Always provide Under-drains
12"
Alternative Drain

TYPE D
For heavy water-retaining Soils and other uncertain made Ground - Heaviest Traffic and Cars
Provide Surface Drains

COMMITTEE ON WAY MATTERS—RECOMMENDED FOUNDATION CONSTRUCTION DESIGNS

This report on track foundation also contains a tabulation of the characteristics of track construction in North America as reported by seventy-eight cities; a bibliography of proper foundations for track in paved streets; an article describing foreign street railway construction, and an appendix containing definitions of the various terms used in describing roadbed, track, ballast and ballast materials.

USE OF T-RAILS IN PAVED STREETS

T-rails in paved streets received the thorough consideration of the committee having this subject in hand. After analyzing what had been done since the first committee on this subject was appointed in 1907, it was deemed advisable to consider the points for and against the use of T-rails in paved streets. The chief points in favor of its use are as follows: First, the T-rail is generally considered to be designed on better mechanical lines. Second, more satisfactory mechanical joints can be manufactured, partly because of the symmetry of the rail outline. Third, the flangeway is more suitable for different wheel flanges. Fourth, the rails have a longer life as a rule, under equal traffic, with a lessening of street openings for renewals. In theory the life of the ordinary joints is probably longer, with a lesser amount of disturbance of pavement at the joint. Fifth, many installations of T-rail in paved streets in recent years have satisfactorily met the local conditions. Several cities have required the adoption of high T-rails in replacement of tram and girder-grooved rails. Sixth, much objection has been improperly directed against T-rails when it should have been brought against the pavement. This has been proved by the installation of modern pavements with old high T-rails.

The points against high T-rails are as follows: First, it is more expensive per foot of finished track and pavement. Second, the lack of a self-cleaning flangeway. Third, increased wear of pavement adjacent to rails, under extreme traffic conditions, resulting in high paving maintenance. Fourth, it is apt to offer a greater resistance to vehicular traffic. Fifth, difficulty in preventing seepage of water in flangeway.

Replies to data sheets sent out by this committee show that at least nineteen different types and arrangements of paving between the gage lines of T-rail tracks are in general use. The total trackage of the companies included 2241 miles of T-rails of all sections, of which 1086 were represented by rails of 6 in. or more in height. From these data sheets a tabulation of the paving used between the rails is as follows:

	Miles
Concrete	19.48
Asphalt	404.19
Slag brick (scoria)	49.67
Macadam	86.05
Granite blocks	635.85
Wood block	84.41
Brick	724.93
Bituminous	37.27
Asphalt block	2.88
Other pavements	196.24
Total	2240.97

On the question of cost of maintaining pavements in T-rail track construction, very little accurate information was obtainable. The tendency throughout the replies, however, indicated that the cost of maintaining paving along T-rail was somewhat greater than girder rail, but that this was offset by the T-rail's improved wearing qualities.

As a result of its study of the data sheets the committee reached the following conclusions: First, there is a diversity of opinion among member companies regarding the use of T-rail in paved streets. Second, that granite or brick headers along the gage lines and under the head rails are most generally used. Third, that Portland cement grout or asphaltic cement grout is the most desirable means of filling the space next to the rails. Fourth, that the tendency of vehicular travel to follow the tracks is about as heavy with T-rails as with other kinds of rails. As a general proposition, the committee could not recommend the use of T-rails for all conditions, and it believed that the limiting conditions were usually reached in the congested portions of city streets. It also recommended that when T-rails are to be laid in permanently paved streets, they should be 7 in. in height, in order to permit satisfactory pavement construction.

PAVEMENT FOR USE IN CONJUNCTION WITH GIRDER AND HIGH T-RAILS

Although the committee was not able to give this subject the consideration it demanded and recommended that its work be continued during the ensuing year, some valuable data were collected and presented regarding the need for traffic records. The report stated that records of this kind were of utmost importance and utility to engineers connected with construction, maintenance and use of streets, and particularly in arriving at a recommended practice for the pavements to use with girder and high T-rails. Since there was no standard method of recording and comparing traffic on streets of the same city or in different cities, the committee endeavored to suggest a uniform method of recording, analyzing and standardizing quantity and weight of traffic on a unit basis.

As a result of their study, the committee decided that the records should be based on simple, accurate methods of counting, recording and reducing the traffic to standard units of quantity and tonnage. In addition this method should be such as to make it easily understood and applied. The period to be covered by any traffic count should be fourteen consecutive hours from 5 a. m. to 7 p. m. and during six consecutive or different week days. However, if average weather and traffic conditions are known and selected, the record may cover only three consecutive week days. Traffic counts should not be taken in abnormal weather, such as seasons of snow and ice, nor during continuous rainy, very hot or excessively cold days, and holidays. The count should be taken at or near the center of the block and not at street intersections and should include traffic both ways. Preferably the observer should be stationed in an elevated position, a second-story window facing the street being most satisfactory.

The committee also presented a general classification of vehicles for practical results as follows: Horse vehicles, subdivided into one-horse, two-horse, three- or more horse and motor vehicles. In computing weights, the horses as well as the vehicles must be considered, because both are factors in pavement wear. For record purposes the average weight of one-horse vehicles, empty and loaded, can be taken at one ton; two-horse vehicles, at two tons; three-horse or more at four tons. Similarly the average of all motor vehicles, empty and loaded, for transportation of persons and goods may be taken at one and three-quarter tons. Bicycles, motorcycles and saddle horses should be excluded A form of traffic counting slip was also designed and recommended by this committee.

ALLOYED STEEL RAILS

This subject was merely a continuation of the review of the subject of alloyed steel rails begun by the committee on way matters in 1912. One of the most striking things observed in this study was that the tonnage of alloyed steel being rolled into rails of all sections has been declining for the last three years. The production of Bessemer steel rails also has been steadily declining, while the production of open-hearth rails has been increasing at approximately a corresponding rate. In other words, the indisputable tendency is toward the more general use of open-hearth rails, which tests have shown to have greater wearing qualities than Bessemer rails. On the other hand, while open-hearth rails cost 7 per cent more than Bessemer rails, purchasers are loath to pay any more to obtain the additional wearing qualities which would be furnished by an alloyed steel.

As a matter of general interest, however, the following table of special steels possessing the general characteristics mentioned, is shown:

Kind	Steel Containing	General Properties Anticipated
Titanium	0.1 per cent metallic titanium	Less segregation, cleaner metal, hence, longer life.
Nickel	3.5 per cent nickel.....	Increased life.
Nickel chrome	Containing varying percentages—nickel and chromium	Increased life by being tough and hard.
Manganese ...	About 12 per cent manganese	Very tough and hard, cannot be easily cut or drilled, wears slowly.
Electric	Made in electric furnace.	Very clean steel, free from impurities, thus adding life.
High silicon..	About 0.35 per cent silicon	Increased life. Much used in England.

The four types of foundation construction submitted for adoption as recommended designs by the way committee were in turn submitted to the committee on standards. This committee recommended that the types be referred back to the committee on way matters for further consideration, since some of the designs do not, in the committee's opinion, represent the best modern practice.

COMMITTEE ON HEAVY ELECTRIC TRACTION

The report of the committee on heavy electric traction of the Engineering Association included a revision of the recommended designs covering clearances for overhead conductors, the revision consisting in a diagram giving a 15-ft. 3-in. clearance for overhead d.c. conductor rails. A continuance of the subjects of clearance lines for third-rails and of the study of modern electric locomotives was recommended for the ensuing committee. In connection with this report the committee on standards approved the proposed clearance for overhead conductors as a recommended design.

Appalachian Power Business

Much new business has been obtained recently by the Appalachian Power Company, Bluefield, W. Va. In talking with a representative of the ELECTRIC RAILWAY JOURNAL M. A. Viele, of Viele, Blackwell & Buck, consulting engineers of New York, who is vice-president of the company, spoke of the contracts for energy which have been closed recently.

The Appalachian Power Company began to deliver energy on Aug. 1, 1912. It has a large potential market in the southwestern part of Virginia and the adjoining section of West Virginia. In the last few weeks fifteen contracts have been closed with coal-mining companies. They had been pending for some time, and their final execution was made possible by the increased output of coal resulting from the new markets opened by the European war. The power company was not delivering energy to any of the coal-mining companies in this list on Sept. 1, but it will be delivering to all but one of them on Jan. 1, 1915. It is estimated by Mr. Viele that the gross revenue from these companies for the first year will be from $55,000 to $60,000, and that in 1916 it will be between $85,000 and $90,000. The total gross revenues of the company thus far in 1914 are about 15 per cent greater than in the corresponding period of the previous year.

The company is prepared to finance its construction requirements. Its securities were underwritten on a basis providing for the completion of the construction necessary for the use of the entire estimated output. A construction program was arranged which covers the period to June 30, 1916. The capital provided for construction purposes has been divided into regular amounts, and these have been expended in accordance with the program. The company, however, is ready to hasten its work and open more developments if the market for energy warrants this change in plan.

The Improvement Club—An American Institution

The Author Outlines the Evolution and Methods of Local Organizations Formed for the Purpose of Bettering Conditions, Including Street Car Service, in Various Sections of a City

BY W. T. BUCHANAN, PUBLICITY MANAGER, PORTLAND RAILWAY, LIGHT & POWER COMPANY

Ofttimes when sitting back of a mahogany desk, in a ten-story skyscraper, figuring out street car service in the hope of satisfying both the stockholder and the patron, a knock comes at the door and the secretary announces the presence of the president of the Skookum Street Improvement Club. As he enters the room you note that the lines of the visitor's face are rigid. He carries himself with an air of knowing just what he is after. Evidently he proposes to hit from the shoulder. You put on your best smile, grasp his hand and tell him that you are delighted to meet him. He begins with a complaint, maybe of the service—which is for more cars on Skookum Street, 10 miles from the business center—more often it is a demand, and once in a while it is a favor that he asks.

How familiar this mental picture must be to every president and general manager of a public utility when reviewing his own experiences with this wondrous individual—the "president of the improvement club." He is an American institution—the outgrowth of our boasted democracy, and his like is not to be found in any other country. His counterpart does not exist in Europe. He is indigenous to American soil. What consideration shall we give him in the general scheme of publicity to educate the masses to a better understanding of the aims and purposes of a public utility? The man who presides over a street railway company of any size will agree that this individual has a very important relation to its gross earnings.

Withal the president of the Skookum Street Improvement Club is a peculiar individual. Sometimes he carries a chip on his shoulder. He smilingly informs you that he has read Mellen's testimony as to the New Haven operations before the Congressional committee. He, if you take the trouble to inquire, will tell you that he recently perused an interesting article in *Hearst's Magazine* on "Municipal Ownership." He is familiar with *Everybody's*, the *Cosmopolitan*, and in a daily paper he is a constant reader of all items telling of the relation of the company with the politicians. He says he knows all about "the jokers" in the franchise—as told to him by some politician or by having read of them in the newspaper having a "punch." Not infrequently he is a believer in socialism. Ordinarily he is saturated with the dope of the muckraker. Sometimes he is amenable to reason, and occasionally he is fair and desirous of getting at the truth. Even then he often dreams that the presidency of the Skookum Street Improvement Club will land him into a fat and healthy political job. There are none to deny that this man is an important element in the public utility field. Every manager has met him time and time again, and each one has a different method of handling him.

How came this man into the commercial make-up of our country? He is a brand-new factor—his existence was not known thirty years ago, when the horse car was the only means of city transportation. In those days, if the car got off the track he was ready to put his shoulder to the back shield and help put it on the track. Now he makes a bee line for the president's office to make known his complaint.

The improvement club or association is really a by-product of the electric railway. It was the electric railway that brought within reach of the business section the suburban territory. Before that time the horse car would not permit of long street car lines as they exist to-day. In moving out along the electric railway the citizen found he needed paving, sewering and all the various conveniences of city life. Being somewhat isolated he found that his requests were not heeded at the city hall, and this led him to forming improvement associations. These associations linked their efforts with neighboring associations, and now nearly all large cities have even a central civic association composed of delegates from each of the neighborhood clubs.

The growth of the improvement clubs in all the cities of the country has been one of the marked characteristics of urban development. Some idea may be gathered from the following statistics as to the number of improvement clubs in Western cities.

Kansas City	112	Omaha	68
St. Louis	242	Minneapolis	181
Denver	64	Portland, Ore.	62
San Francisco	262	Seattle	73
Los Angeles	182	Dallas, Tex.	54
Milwaukee	150		

Think of 100 small organizations, in one city, acting as regulating bodies for whatever portion of the street car service that might take the fancy of the members of the clubs.

Have you ever attended one of their meetings? Usually only ten or twelve members are present. It appeals to the visitor as a sort of neighborhood affair. Hundreds of citizens living near the meeting place never attend and only know of the existence of the club through reading of it in the newspapers. If it is desired to secure additional cars, a new fender, a lower step, or a reduction of the fare, the modus operandi of starting the movement begins after this form. A meeting of the club is called. Ten members attend. A resolution is passed—perhaps it was prepared by the leader downtown in a lawyer's office—and with this resolution in the hands of a committee on which the president usually acts ex-officio he starts for the newspaper office and has it printed. "It's news," says the city editor, and that is sufficient dictum to send the stuff broadcast without regard to the truth of the claims set forth. Then comes another meeting of the club, fiery speeches are made, the newspapers print reports of them, and the campaign is on. What sort of action is needed to secure the co-operation of these clubs toward a sound and sane treatment of the community's most important business enterprise?

THE RECORD IN ONE CITY

It is a well-established fact that in cities like Milwaukee, Kansas City, Omaha and those on the Pacific Coast, practically all matters of a disturbing character start from the improvement club. Here is a list of new projects involving either capital expenditure or loss of revenue which were under discussion by the improvement clubs during one winter season in a Middle Western city: Crosstown lines; lower steps; six tickets for a quarter; new fenders; double tracking; no-seat-no-fare; express service; bridge tolls; no-stop cars; paving; heating of cars.

The above, if put into effect, would involve an expense of a million dollars or more. If any deduction is to be derived from the experience of this Middle Western city, it is the wondrous ability of an improvement club in starting an agitation which became more or less effective. In the case of the Middle Western city the crosstown line was finally agreed to by the local public utility. The lower steps agitation was mothered by the Women's Club and won in a jump. The six-tickets-for-a-quarter scheme was defeated in the courts, new fenders were ordered, the no-seat-no-fare lost out, bridge tolls were adjusted and the paving bill runs higher and higher.

It is evident that the improvement club has within it all the elements which go to make trouble for the manager of a public utility unless he can secure its co-operation. Many are the plans devised to bring about co-operation between the improvement club and the public utility. The first element to be considered is the character of service rendered the public by the utility. Cheap goods at high prices have no place in the game of publicity. Co-operation cannot be secured if the bargain is left handed with the jughandle in the grasp of the utility. Street car men are merely merchants. They have a given commodity to sell, and it is no different than the sugar of the grocer. To secure co-operation there must be good service rendered. With this fundamental to begin with the opportunity for publicity of an appreciable character is an inviting one.

There should be a close contact on the part of the utility with each club, particularly its officers. There should be a complete list of all the members, their house addresses, their occupation. A neighborhood club too often takes into account only its immediate section without relation to the hundred or more neighborhoods throughout the system, and it is this broader relation that should be impressed upon the members. To any one who has much to do with the improvement club it is apparent that there are difficulties in the way of convincing those who have the political bee in their bonnets and have a sinister purpose to accomplish at the expense of the utility. With these persons the contest takes on the character of a battle of wits, and not unfrequently the man with "a sinister purpose" is defeated.

THE PSYCHOLOGICAL TIME TO CUT SERVICE

In explaining the present dull business of the country President Wilson, in talking to the representatives of the National Vehicle and Implement Dealers' Association, remarked that the "trust" legislation proposed no doubt was having a depressing effect, but he regarded the present era as "psychological" for the correction of evils which later on, if permitted to run, would even create more suffering. The President's term "psychological" as applying to the present situation finds a counterpart in the utility field. What the President no doubt means is that an early day cure involves a milder dose of medicine to take than permitting the fever to run its course. While the President's viewpoint as to trust legislation does not meet with the writer's approval, his method of reasoning—taking the trouble by the nape of the neck—has much in it that can be commended. There is an incident now in process of incubation with an Eastern utility which is being watched to find the "psychological moment" for action. The situation is something like this: The company found its gross earnings falling off as a result of lessened travel upon the street cars. The apparent need of reducing the service was manifested, and the order went out to "cut." There is no feature of the relation between the public utility and the community which is so delicately attuned and so responsive to public displeasure as the street car service. Take out any cars on a given line, and within a very short time there will be a delegation in the railway president's office entering serious objections. In the case in question the lines were tightened by making faster time, and here and there was an actual reduction of the service. The first manifestation of displeasure came from the men who were let out. They told their neighbors. A week or more rolled round, then came a brief notice in the newspaper. Another week there was a letter written to the newspapers by a patron complaining of the service. The next step will be the call of a reporter. Later on the improvement club will take up the issue. Then perhaps there will be a complaint filed before the public utility commission, and an investigation will follow.

If the situation is not handled with care the ire of the public will be taken out in some form of drastic legislation. The point to be attained is to discover the precise moment for action to avoid the usual holocaust. In other words, when will the "psychological" moment appear? Shall the old service be put on for a week or more only to return later on to the cutting process and thus jockey along until the public has forgotten the incident? The interesting feature of the experiment now being undertaken is to note each step made by the public. Apparently only a very small portion is aware of the cutting down. This is due to the skill with which the schedule man is handling the car line, and it may be that the skill of the schedule man will save the day. It must be conceded that the least said about the changes the better. To announce a reduction in the service in the public press and thus to commit the proposition to the "direct" method of publicity would only produce the storm to be avoided. The situation of this Eastern utility is not an unusual one, although it has features out of the ordinary: a heavy fixed charge, a large track mileage and long lines. The public views with complacency the fixed charge and feels that the service should be adequate. Its conception of an adequate service is not in accord with the heavy fixed charges, and the outcome is being watched. What will be the next move? And when will be the "pyschological" moment to bring a peaceful solution of the difficulty?

If advice is to be given it would be to go slow with the changes and the cutting down process. If it is to be admitted that the "indirect" method is a better one, then the process should be very slow. There should be co-operation between the club and the management. Ordinarily the citizen will realize the full force and effect of dull times and for that reason may admit of a slight cut. However, each move will prove an interesting chapter in the book of "Cutting Down the Service."

SUGGESTIONS AS TO WHAT TO DO

An experience of years with the improvement clubs has brought these conclusions to the writer:

Keep in close touch with all of them. Upon the very first appearance of trouble meet the members more than half way. Let them be free to come to the office. Treat them as a very vital element in the business of the day. Make apparent the difficulties of operation, and let no stone go unturned which will bring about the co-operation so heartily desired. The improvement club is one of the most vital factors in the utility field to-day.

Changes in Taxation Laws

Abstract of Report of Committee on Taxation at A. E. R. A. Convention, Showing Modifications in State Tax Laws—Franchise Tax Burden on User—Gross Earnings Tax Truest Measure of Property Value

The committee on taxation confined its efforts this year to an endeavor to keep abreast of the changes in the taxation laws of the various states. Thirty-five states reported no change. From four states no report was received, namely, Arizona, South Dakota, Tennessee and Wisconsin. Iowa reported the passage of a joint resolution calling for an amendment to the constitution to be submitted to vote not before 1916. It provides for the classification of property and the exclusive taxation of property so classified for state purposes. Maryland created a tax commission. Massachusetts changed its method of taxation of foreign corporations and provided for the levying of an income tax. Minnesota passed a bill classifying property for purposes of taxation. The Oregon tax commission changed its method of valuation, which resulted in an increase in taxation.

From the tables prepared by the bureau of the census, the percentage of gross earnings paid in taxes by electric railways in the various states has been computed for the years 1902, 1907 and 1912 as shown in the table on page 926.

SPECIAL TAXATION

At a meeting of the National Tax Association, the committee on taxation of public service corporations submitted a report in which is discussed the question of "the equalization of taxation upon public service corporations subject to ad valorem taxation." Attention should be called particularly to this expression of the committee:

"A generation ago, before states and the nation had undertaken to regulate effectively, through commissions or otherwise, the service and charges of public service corporations, this theory [i.e., special taxation much heavier than that imposed on other classes of business or property because they hold special franchises of great value] offered a natural and logical remedy for some of the evils of unregulated monopoly.

"But the situation changes when public service corporations are brought under effective regulation. Under the latter condition, regulation of rates and service must proceed upon the theory that the corporations should be allowed to earn a reasonable return upon a fair valuation of their property. Special taxes upon regulated monopolies, therefore, merely increase the expense of providing the service and increase the rates necessary to allow a reasonable return, or else diminish the resources available for extending and improving this service.

"It is through public regulation and not through taxation that a correct policy toward public service corporations must be worked out, and theories of taxation should be based on the assumption that public service corporations are to be subjected to public control."

In the special report on taxation, of the bureau of corporations of the federal government, issued December, 1913, the federal government notes the change in the method of taxation of public utilities in Rhode Island by the creation of a permanent tax commission and the imposition of a tax of 1 per cent on the gross earnings from operation of street railways within the state in addition to the tax of the same amount heretofore levied by the state as well as to the general property tax on the tangible property of the companies. The new tax is in lieu of other taxes on intangible personal property and exempts holders of stocks, bonds and other evidences of indebtedness of such companies from taxation.

The conference of New England state tax officers held in January and December, 1912, adopted a series of resolutions recommending to their several states the classification of personal property for purposes of taxation, an extension of franchise taxes at rates which shall compensate for advantages enjoyed, and, in connection therewith, the exemption from local taxation of those securities whose value is included in the value of the franchise.

The state of Connecticut appointed a commission of three disinterested persons "to examine into the system of the taxation of railroads and street railroads located partly or wholly within the state . . . and to make such recommendations in connection therewith as shall seem to them advisable." The commission appointed by the state of New Jersey recommended, among other things, that public utility properties now locally assessed should be assessed by a state board of equalization with the aid of data from the public utilities board and valuations certified to local taxing districts. A special commission in Colorado recommends that all public utilities be taxed by a central taxing body.

TAX ON FRANCHISES

In a paper on the taxation of public service corporations, Milo R. Maltbie, Public Service Commissioner for the First District of New York, before the second international conference on state and local taxation, said:

"The method of taxing public service corporations which has attracted the most attention within the last few years is the special franchise tax. It is virtually a tax upon the right to use the streets, highways and public places for special purposes. The primary object of the movement for the taxation of franchises has been not so much to increase governmental income as to secure to the public a larger share of the profits of the corporations. Whether investors in public utilities have obtained a larger profit than they have deserved may be an open question, but that the public generally believes that they have is indisputable.

". . . But wherever there is a complete and effective system of public regulation or wherever it may be obtained as easily as the franchise tax, the advisability of attempting to control corporations thereby is open to question. The amounts taken from the public service corporations through a franchise tax may be collected in the long run from the users of the service and not from the stockholders. Under an effective system of public regulation the corporation must, of course, be allowed to earn a sufficient amount to pay all costs of operation and also a fair profit on the capital used. If, in addition, a sum must be earned to pay a franchise tax, the authority exercising public control must allow the corporation to place its rates sufficiently high or to supply service so inferior that it may earn the tax.

"The franchise tax imposes a burden on the user in order that property owners in general may be relieved. If every citizen used the services of the public utilities in direct proportion to his ability to pay, or the property he owns, or any other just standard, the injury would be merely theoretical. But the use of public utilities, especially in cities, usually bears little relation to individual income or property owned. Consequently, every dollar that is taken from public service corporations for the support of the government is likely to be taken from those who are least able to pay."

GROSS EARNINGS TAX

The report of the commission on revenue and taxation of the state of California in 1906 contains the following:

"The true present value of a street car property depends solely upon what can be taken out in gross yield less operating expenses and depreciation. The only item ascertainable with any degree of certainty is the gross receipts. The gross earnings tax is, therefore, suggested by the very fact that any other sort of taxation is uncertain and indeterminate in application and operation and must directly or indirectly refer back to the earnings. It has, moreover, all its usual advantages of certainty and ease of administration, of steady yield and steady growth, of satisfaction to the public and to the companies. It is notable that whenever cities lease or rent franchises for a term of years, they almost universally prefer a percentage of the gross earnings as the annual rental charge to a fixed annual payment. The reasons which incline both parties to regard this as the fairest and most satisfactory form of bargain apply with full force to the question of taxation."

At the sixth national conference, Alfred H. Holcomb, assistant secretary American Telephone & Telegraph Company, said:

"The increasing exemption from taxation of certain forms of personal property, such as moneys and credits, relieves private owners of such property from a burden in a way which is never thought of for public service corporations and which is even impossible of application to them under the special methods which have been devised for the assessment of their property. The 'stock and bond' method, for instance, or the 'net earnings' method reach a value for the entire property, real, personal and mixed."

It seems to be the general consensus of opinion of the closest students of the question of the taxation of corporations, and more particularly of public service corporations, that the gross receipts method is the fairest and truest measure of the value of the property which can be obtained, far superior to the ad-valorem method.

DIFFICULTY OF VALUATION

The difficulty of adequately or fairly valuing the property of a public utility is illustrated by the opinion of Chairman Stevens, Public Service Commission for the Second District of New York, in the Westchester Street Railway case decided April 24, 1912. This opinion is in part as follows:

"An inquiry into the value of a railway property as a whole is an investigation of the question, how much money or other things will men be willing to part with for the sake of possessing such property? The difficulty attending the investigation is: (1) the property has never been, we will assume, bought or sold, so that there is no direct test or evidence of its ratio of exchange; (2) it is not one of a class of things which is bought or sold with such frequency or under such circumstances as to afford a fair test of what it would be likely to bring upon exchange or sale.

"In short, no direct evidence is obtainable concerning its probable ratio of exchange. The only course open to the investigator is to select those qualities or attributes which in his judgment would create a desire for the property and then estimate how much that desire would induce a prospective purchaser to surrender for its satisfaction. The value of a property depends upon its earning power, direct or indirect. To the ordinary investor it is its direct earning power as shown by the excess of its revenues over its expenses. To another road it may be indirect, by furnishing business upon which a profit can be made, or by the suppression of destructive competition. The net earnings rule of valuation, when properly and carefully applied with due regard to all the features of the individual case, is probably the one having the surest support of basic principle."

It has long been apparent to public utilities that their property was not being assessed by the same method as was the property of individuals or mercantile and manufacturing corporations, whether these assessments were made by local assessors or by commissions created for the purpose. This impression is confirmed and some of the reasons therefor well set forth in the second annual report of the Tax Commission of Ohio, which reads to this effect:

"To properly perform his duties under these circumstances requires a degree of moral courage in the assessing officer which is not possessed by the average human, and his returns are more usually works of fiction than of truth. Proper returns have never been and never will be secured until property is assessed by officers whose tenure of office and compensation are made to depend on efficiency and faithful observance of the law."

Commenting on the provisions of the Ohio law which require all property to be assessed at its true value in money, the commission remarks:

"It will be necessary to make some radical changes in the statute before proper results can be secured. Property should be valued as the commercial world values the same. . . . That property of public utilities has not been assessed at the commercial value the slightest investigation will demonstrate. The capital stock and bonded indebtedness of the public service corporations in Ohio, as reported by the commissioner of internal revenue for the year ending June 30, 1911, amounted to $1,690,000,000, with net earnings of $53,118,252, or a little more than 3 per cent on the total capitalization. This commission assessed the property of the corporations in Ohio for the year 1911 at $912,000,000, or a sum nearly equal to the net earnings as stated in that report, capitalized at 6 per cent.

"The capital stock and bonded indebtedness of the industrial, mercantile, manufacturing and miscellaneous corporations in this state, as reported by the commission of internal revenue for the year ending June 30, 1911, exceeds $1,750,000,000, with net earnings of $151,504,400. The property of all the incorporated companies in Cincinnati, not only manufacturing, but mercantile and all other kinds, exclusive of public service corporations and banks, was assessed in 1910 at $17,697,260, or at a little more than 10 per cent of the amount of capital invested by manufacturing corporations alone, as reported by the Bureau of the Census. As the conditions were relatively the same throughout the state, it is certain that the total assessment of all the private corporations in Ohio for the year 1910 would not exceed $150,000,000. These figures were very largely increased during the last year, but it is believed property of this kind is not yet assessed at near its true value."

In support of its contention, the commission later on quotes from the Minnesota Tax Commission:

"The uniform universal custom throughout the entire state has been to assess property at from 25 to 50 per cent of its actual value, and this custom has had the long-continued approval of the people, the silent support of the law-making and the law-enforcing departments of the state government. It is a stillborn statute, unenforced and unenforcible. Any attempt to comply with its provisions would be revolutionary."

CONCLUSION

It is, therefore, perfectly apparent that under present-day conditions, with a full knowledge of the value and capitalization of properties in the hands of the taxing authorities and with none of this information with respect to other properties in the hands of the authorities, and with the voting power of the individual property holder held as a club over the taxing bodies, particularly the local assessor, the electric railway industry, together with other public utilities, is bearing an undue and unfair proportion of the burdens of taxation.

TABLE SHOWING BY STATES PER CENT RATIO OF TAXES TO GROSS INCOME FOR OPERATING AND LESSOR COMPANIES COMBINED

Discussion on Reactance by A. I. E. E.

At the meeting of the American Institute of Electrical Engineers held in New York on Oct. 9 the topic for discussion was reactance in power station and transmission work. This topic is of particular interest to electric railway men at this time on account of the attention devoted to it in the Atlantic City report of the committee on power generation of the American Electric Railway Engineering Association. Two papers were delivered in New York, "Protective Reactances for Feeder Circuits of Large City Power Systems," by James Lyman, L. L. Perry and A. M. Rossman, all of Sargent & Lundy, Chicago; and "Use of Reactance with Synchronous Converters," by J. L. McK. Yardley, Westinghouse Electric & Manufacturing Company.

The first paper continues the discussion of the effects of reactance in power stations covered by the same authors in a paper printed at the 1913 midwinter convention of the institute. The present paper discusses in greater detail the uses and limitations of reactance coils in the feeder circuit of large city power stations. They conclude that in a large city power system, the miles of underground cable and consequently the cable faults increase at a faster rate than the generating capacity. The severity of short-circuits also increases with increased generating capacity. Feeder reactances are particularly effective in reducing and localizing the effect of such short-circuits. When properly proportioned feeder reactances are used, an increase or decrease of generator reactance has only a limited effect on the amount of kilovolt-amperes flowing into a fault. Bus-section reactances in the generating station in connection with feeder reactances still further reduce and localize these effects, even when it might be more desirable to distribute their effect if other conditions permitted.

It would be desirable for many reasons to operate feeders in parallel at their substation ends, but such operation tends to increase greatly the kilovolt-amperes flowing into a feeder short-circuit and to cause other feeders besides the one affected to trip out when overload relays with the usual settings are used.

In his paper Mr. Yardley presented a large amount of original data on the effects of protective reactance on the a.c. side and d.c. side of the rotary converter. Many oscillograms of currents and emfs were reproduced in connection with the paper. He divided synchronous converter installations into several classes for purposes of analysis, namely: those in which it is of prime importance to keep voltage on the lines, those in which heavy overloads are frequent but where the voltage may be allowed to drop off during overload, and those in which brief although frequent interruptions are not objectionable if necessary to protect apparatus. On account of space limitations it is impossible here to even summarize the results of the tests described by Mr. Yardley which have been very recently carried out. Among other conclusions he states that if a properly-designed quick-acting circuit breaker be used, and the proper amount of reactance be placed in the d.c. circuit, it is impossible to flash a converter over, as the circuit-breaker will trip out the circuit before the current approaches the tripping-out flash-over value.

In the discussion D. B. Rushmore, Schenectady, N. Y., called attention to the present-day recognition of the necessity for considering an electrical system as a whole rather than treating each part separately. Formerly the demand was for transformers of low reactance, while now special effort is made to make it as high as possible. Phillip Torchio, New York, claimed that insulated rather than bare wire should be used in reactance. H. W. Buck, New York, stated that long-distance transmission lines possess inherently so much reactance and resistance that protective reactors are not needed so far as the delivery of the line is concerned. J. J. Frank, Pittsfield, Mass., expressed the opinion that, since it has no moving parts, the reactor is the most satisfactory and reliable protective device thus far developed. N. W. Storer, Pittsburgh, said that the protective reactor should be equipped with a quick-opening short-circuiting device to connect the reactor in circuit when the reactance is needed and to keep it short-circuited at all other times.

In line with the country-wide movement to grasp opportunities offered by the Panama Canal and the war in Europe for the expansion of United States trade in South America, J. G. White, of J. G. White & Company, Inc., New York, has established three scholarships in the Spanish language at the Pennsylvania State College. He offered the prizes "as a stimulus to the students to fit themselves for handling Latin-American trade." Mr. White's offer has been accepted.

New Presidents of the Associations

Those Elected Were: Accountants' Association—C. S. Mitchell, Pittsburg Railways; Claims Association, William Tichenor, Terre Haute, Indianapolis & Eastern Traction Company; Engineering Association—L. P. Crecelius, Cleveland Railway; Manufacturers' Association—E. H. Baker, Galena Signal Oil Company; Transportation & Traffic Association—M. C. Brush, Boston Elevated Railway

At the concluding sessions of the four affiliated organizations of the American Electric Railway Association the elections of the new presidents for the ensuing year resulted in the selection of men who have all been active in association work, and who may be expected to maintain the high standard of past activities in cooperating with C. Loomis Allen, the new president of the American Association, of whom a biography was published in yesterday's issue. Brief biographical sketches of these new officers as well as of the newly elected president of the Manufacturers' Association are given in the following paragraphs.

Matthew C. Brush, who was elected president of the Transportation & Traffic Association on Thursday, is second vice-president of the Boston Elevated Railway. He graduated from Armour Institute in 1897 and from the Massachusetts Institute of Technology in 1901, and soon after graduation took up work in the mechanical and transportation departments of the Union Pacific, and Chicago, Burlington & Quincy Railroad. While in steam railroad work he acted as machinist, foreman, and roundhouse foreman of the Union Pacific Railroad with headquarters at Omaha, Neb., and he was general foreman in charge of shops and roundhouses of the Chicago, Rock Island & Pacific Railroad. He also secured some experience in steamship traffic in the Great Lakes district.

In 1904 he entered electric railway work as general manager of the Boston Suburban Electric Companies, which operate an extensive system of suburban electric railway lines west of Boston with headquarters at Newton. Soon after he was also elected vice-president of the system. Here he carried forward a constructive policy of strengthening public relations, systematizing operation and placing the entire system upon a firm financial foundation.

In the spring of 1910 Mr. Brush accepted the position of general manager of the properties controlled by the Buffalo & Lake Erie Traction Company, with headquarters in Buffalo, but returned to New England in November of the same year to become assistant to the vice-president of the Boston Elevated Railway. He was elected to his position as vice-president of the Boston Elevated Railway Company early in 1912.

In all of the positions which he has occupied Mr. Brush has made constant efforts to promote friendly relations with employees and with the public. He is credited with the first successful attempt to secure sixcent fares on a large scale on a New England system. In his present position he has had charge of the efficiency work of the company and has waged a warfare against preventable losses, and on behalf of service improvements. He has taken an active interest in railway association work, notably the New England Street Railway Club and the American Electric Railway Association. Since Mr. Hegarty's resignation he has been acting president of the Transportation & Traffic Association, and showed by his conduct of the sessions of this association at Atlantic City that he has those qualities which will enable him to administer the duties of his new office in a most efficient manner.

L. P. Crecelius, who was elected president of the Engineering Association on Friday, was born in St. Louis, Mo., in 1879, and received his educational training in the public schools of that city and in the St. Louis Manual Training School of Washington University. After completing this course he began an apprenticeship in power plant work with the Southern Electric Railway Company as plant electrician in 1899. When this company was later consolidated with other electric railway properties into the United Railways he continued in the power department of the new company in various capacities. In 1896 he left St. Louis to go to Newark, N. J., to accept the position of assistant superintendent of overhead construction of the Public Service Railway under Albert Stanley. He gave up this position in 1907 to go to Cleveland, Ohio, where, after the readjustment of traction affairs in that city, he was engaged to assist in appraisal work. In 1910 he was appointed by John J. Stanley to be superintendent of motive power and electrical engineer of the Cleveland Railway. He continues in this work at the present time and has had a great deal of interesting work in connection with the rehabilitation of the power distribution and substation equipment of the company.

M. C. BRUSH
President Transportation & Traffic Association

L. P. CRECELIUS
President Engineering Association

Mr. Crecelius is an active member of the American Electric Railway Engineering Association and of the American Institute of Electrical Engineers. In the former he has naturally specialized in the direction of power generation, having been chairman of the power generation committee in 1912 after membership in the committee for two years. He began his active work in the association on the car wiring committee about 1907. During the past few years he has been especially interested in the development of the 60-cycle converter and presented a paper on this subject recently before the Cleveland Section of the American Institute of Electrical Engineers. He contributed an article on the same general subject to the 1914 report of the committee on power generation of the Engineering Association. Mr. Crecelius has an inventive turn of mind and an inspiring enthusiasm for his work. As vice-president of the association he has become familiar with its administrative problems.

C. S. Mitchell, who was elected president of the American Electric Railway Accountants' Association at Atlantic City on Oct. 15, has been third vice-president of the association during the past year. He has long been active in the association, has been a member of different committees for a number of years and has been a member of the association since 1900. Mr. Mitchell's railway experience has been entirely in Pittsburgh. He was born near that city and entered the auditing department of the United Traction Company of Pittsburgh in August, 1897. In 1899 control of the road was purchased by the Philadelphia Company which in 1902 acquired all of the surface railways in Pittsburgh. At that time Mr. Mitchell was appointed auditor of the combined property and continued in that position until 1912, when he became controller of the company.

C. S. MITCHELL,
President Accountants' Association

WILLIAM TICHENOR,
President Claims Association

William Tichenor, the new president of the American Electric Railway Claims Association was born in Lewis, Ind., in 1859. After completing his education in a country school, he taught school for ten years. During this period he married, and in 1891 moved with his family to Ann Arbor, Mich., where he studied law in the University of Michigan. He graduated in 1893 and soon after completing his law studies, moved to Terre Haute, Ind., where he began the practice of law. In 1896 he was elected prosecuting attorney of Vigo County, served two years in this capacity, and then returned to the practice of law in Terre Haute.

In January, 1905, Mr. Tichenor was made assistant attorney of the Indianapolis Traction & Terminal Company. Later when Hugh J. McGowan, then president of that company, purchased and merged the lines which now form the Terre Haute, Indianapolis & Eastern Traction Company, he was made claim agent of the company and he holds this position at at the present time. He became a member of the Claims Association at the Columbus convention in 1906 and has attended every convention since that time. During the past two years he has served as second vice-president and first vice-president, respectively, of the association.

E. H. BAKER,
President Manufacturers' Association

Edwin H. Baker, the newly elected president of the American Electric Railway Manufacturers' Association, has a widespread acquaintance and rich experience in association and railway affairs which eminently fit him for the position to which he has been elected. Mr. Baker was born in Brooklyn, N. Y., March 4, 1853. He attended school in his home city and graduated from the Brooklyn Polytechnic Institute. His first business position was with S. T. Baker & Company, with whom he remained from 1873 to 1894. Then he entered the service of the Galena Oil Company, now the Galena Signal Oil Company, of which he is second vice-president.

Mr. Baker was elected a member of the executive committee of the Manufacturers' Association in July, 1905. He served as chairman of the finance committee in 1904-1905, as treasurer in 1906, and for three years has been vice-president in charge of exhibits. He is a member of the following clubs: Brooklyn, New York Railroad, New York Yacht, New England Street Railway, Empire, Boston Railroad and Pittsburgh Railroad.

First Lecture in Correspondence Course

The first lecture in the correspondence course for electric railway accountants conducted by John R. Wildman, professor of accounting New York University, School of Commerce, Accounts and Finance, is to be mailed on Oct. 19. The lecture discusses first the purpose and scope of accounting, this subject after the general introductory remarks being taken up from the standpoint of the purpose of the systems of accounts established by public service commissions. Professor Wildman then mentions the factors that produce income, namely, land, labor, capital and business organization. In connection with the latter point, valuable information is offered concerning the economic phases of organization. Later an extended discussion of the legal phases of business organization is given, showing the proprietary or capital accounts that are used under each form and the legal method of organization, rights and liabilities that characterize each form. Trusts, including consolidations, mergers and holding companies, will be discussed more in detail when the preparation of financial statements is studied. The lecture contains at the end references for collateral reading and the first quiz for the members of the course. The latter consists of an essay regarding various features of the corporate and financial organization of the correspondent's company.

It is stated that the names and marks of the ten men submitting the best quiz papers will be published in the lecture next month.

A recent issue of the *Electrical Review*, London, gives the total value of British export trade in electrical goods in August as £238,621, compared with £564,291 in July. The principal markets for the August electrical exports were: Canada and Newfoundland, £14,960; Argentina, £37,269; India, £40,215; Victoria, £13,778; New South Wales, £14,155, and New Zealand and Fiji Islands, £11,309. The United States, Philippines and Cuba received £1,476 from Great Britain during August, and Germany received £5,768. The principal item of export was machinery which had a value of £86,789 or, roughly, 37 per cent of the total. The registered electrical imports into Great Britain amounted to £86,734, having fallen from £291,244 in July. The principal countries supplying this trade were the United States, £39,426, and Germany, £24,953. The corresponding German figure in July was £168,000. The principal item of import was machinery. It was valued at £29,152 or, roughly, 34 per cent of the total. During the month the British re-exports amounted to £10,001.

South American Trade Opportunities

Several speakers discussed South American trade opportunities at a lunch of the Merchants' Association of New York, held at the Hotel Astor on Oct. 14. Those who spoke were W. S. Kies, manager foreign trade department National City Bank of New York; John F. Fowler, vice-president W. R. Grace & Company, New York, and Charles M. Pepper, former foreign trade adviser of the Department of State. Nearly 1000 people attended the lunch.

Mr. Kies explained in detail the plans of the National City Bank for the opening of two branch banks in South America. The decision to open these branches, which was reached in June, before the commencement of the European war, was made possible by the new federal reserve law. It was mainly through the assistance of German and British banks in South America that the trade of Germany and Great Britain with South American consumers had been built up to large proportions. It was well understood that a regular provision in the loan arrangements between those banks and South American borrowers required that the proceeds be spent with manufacturers in the countries which advanced the funds. When the new banking act was passed many inquiries as to the possibilities of foreign business were received. As a result of these, 6000 letters were sent by the bank to exporters and importers, and the responses showed that American manufacturing interests had suffered from lack of banking facilities in South America. Within a few years the development of trade with South America would lead to surprising and satisfactory results.

Mr. Fowler said that there was no mystery about South American commerce, but that it required care and meant large and long responsibilities. Long before the European war was started there was a general business distress in South American countries. Each South American country would have to learn, one by one and each in its own way, how to face the present problem and how to get on its feet again. The buying power of South America, Mr. Fowler added, was much crippled and would remain so for some time. It must not be imagined that all exports from Europe to South America were cut off. Up to the time of the present economic distress in South America trade between this country and South American countries had been increasing. Mr. Fowler expressed the belief that hereafter this country would enjoy a larger share of the commerce of South America. As a market South America had not been neglected by this country. There was not a small town in South America that was not ransacked for orders on behalf of merchants and manufacturers in the United States.

It could not be expected that this country, under the conditions that had prevailed in the past, would take as large a share of South American trade as would Europe with its population of 450,000,000 comprising both producers and consumers. That population was to be compared with the 100,000,000 of this country, most of whom were pretty well contented with what they got at home. The new tariff law, however, was a sign that this country was prepared to buy more from the rest of the world than it had done before. Hereafter this country would increase steadily the volume of its purchases from South American countries.

The present was an opportune time, Mr. Fowler said, but the prospects must be considered earnestly and sensibly, not hysterically. A great deal of what had been preached lacked common sense. It always had been European capital that stimulated South American countries. If capital from this country could be sent to the assistance of South American countries, it would help greatly to develop future trade. Referring to the frequent reproaches against exporters here on the score of niggardly credits, Mr. Grace said that our exporters had been very liberal and much more so than they would be in home trade. Whether he bought in Europe or here, the worthy South American trader had about the same credit facilities. Wherever situated, it was the unworthy customer who howled the loudest when merchants would not give him dangerous terms. Shipping facilities, Mr. Fowler declared, were relatively as good to South America as to Europe, and there was no complaint to be made about freight rates.

In conclusion, Mr. Fowler mentioned some "don'ts," which briefly were as follows: Don't use second-hand packages. Don't use boxes carrying old ship marks. Don't advertise contents on the outside of packages. Don't forget that freight is frequently discharged on rough seas. Don't forget that the customer wants to receive goods on time. Don't forget to give good service with reasonable charges.

Mr. Pepper declared that South America was one of the great and growing markets of the world and should be studied in that attitude. He advised manufacturers to establish permanent exhibits of products in large South American centers. This country was reaching the period when a great many more manufacturers must have foreign markets.

Lessons from the South American Experience

Col. Herrera de Hora, in giving to a representative of the ELECTRIC RAILWAY JOURNAL the story of his thirty-odd years' experience in South America, stated that in 1880 he began electrical pioneer work there with the Bell telephone and the Brush electric light. This succeeded well, and if the industry had been judiciously fostered by extending a fair amount of credit, so as to enable the people to digest the new industry, America would have been pre-eminent in the electrical enterprise. Our manufacturers, however, says M. de Hora, saw fit to insist in almost all instances on practically cash transactions with the result that the Englishman entered the market. Having banks, such as the London River Plate, the London & Brazilian, the British Bank of South America and several others, through which they had been in the habit of extending credit for Manchester goods from six months to periods of eighteen months and two years, they attacked the electrical market on the same credit lines, so that the American orders rapidly fell off and by 1890 most of the trade was in English hands. The Germans then came along, and by means of hard-working and courteous representatives who spoke the language, by means of metric catalogs in Spanish and Portuguese, and by means of manufacturing to order, they succeeded in ousting the British. At the outbreak of the present European war Germany practically controlled the electrical supplies of the whole South American continent, although their goods are inferior in most cases to the British and more so to the articles supplied by American manufacturers.

If our manufacturers wish to succeed in South America they can only do so by taking a leaf out of the Germans' book. They must endeavor to satisfy in every sense their customers, by sending an experienced and tactful representative speaking fluently the languages of the countries he visits, to study conditions, ascertain the status of the business people, make friends and social acquaintances and, most important, find out the exact requirements of the various purchasers. Then they must fill those requirements without one hint of substitution and with especial care in packing. American manufacturers must not forget that South America is full of shrewd business men, honest and reliable. They are naturally proud of the progress made by their various countries and they can be reached only by gaining and holding their entire confidence.

COMMUNICATIONS

Using the Technical Journal

STONE & WEBSTER

BOSTON, MASS., Oct. 6, 1914.

To the Editors:

I note with interest in the issue of Oct. 3 an abstract of Mr. Alvord's paper on "How to Use a Technical Journal," and I could wish he might follow it with a second paper, pointing to the solution of several problems, questions that must almost of necessity confront every engineer, whether he be classed as "young," "middle-aged" or "mature." Mr. Alvord says that he, himself, maintains a file of clippings and abstracts, a practice which, I believe, has proved very satisfactory to most engineers who have adopted it. I would be surprised, however, to learn that he does not let any questions go unanswered —or answered by mere guess—because he has not a clipping on the subject and does not know where he may readily find the needed reference. Therefore, I would plead for a better way of rendering available a great deal that is valuable, but effectually lost, because apparently too insignificant to index, or because it appears as part of an article under a different title.

I have long urged that the library world should so organize as to provide a custodian for every idea and every article needed by men in business or professions. It is easy enough to lay out such an organization on paper, but not easy to get people to believe in it, much less to finance it. The mere system of indexing is not a matter of greatest difficulty, but it is difficult to decide how far to go, i. e., to decide what is merely waste and what needs to be particularly cared for. A librarian not having use for an article himself, may trust too much to the titles and names of writers, while often the technical man scorns what is not of use to-day.

I believe, however, that we are evolving toward a system in which the specialists are to be held morally responsible for information and sources of information kindred to their specialties. For instance, in the needed system, if two engineers are particularly interested in good roads, one would hold himself responsible for the literature of tar macadam roads, and the other for that of wood pavements, assuming that the whole literature of roads and pavements is too much for one man. This would be a step toward contributing to the support of a special library on roads, which would naturally know who are the specialists. This same idea carried to its ultimate development is what we need the country over, professional men of every description standing sponsors for, or subscribing to the work of, those who will collect the information and have it available when wanted.

I would hold publishers of journals responsible to maintain card indexes of substantially everything that goes into their journals, so that they can hold up their right hands and say, "Nothing has appeared in this journal in the last ten years of more than six lines in length that we cannot lay our hands upon."

Such refinement is, I believe, a matter of the near future, because men in their earning capacity are realizing more and more that they need to know what other men have said that pertains to their immediate problems. Believe that the well-trained librarian can generally advise about the ways and means of getting information on almost everything, and insist that he thus make himself useful to you. He may tell you that John Smith has a still better clipping file than yours, and you may need to thank the librarian for putting you in touch with your superior. G. W. LEE, Librarian.

Insert Special Work Failures

THE MEMPHIS STREET RAILWAY COMPANY

MEMPHIS, TENN., Oct. 7, 1914.

To the Editors:

I have read with interest the very exhaustive articles on "Insert Special Work Failures," in Nos. 12 and 13, Vol. 44, of the ELECTRIC RAILWAY JOURNAL. I thoroughly concur in all you have to say and wish especially to emphasize what you have said in regard to the proper installation of special work. It is difficult to instill into a foreman the exact care necessary to get the best results. I believe that the life of a complicated layout of special work can be increased fully 50 per cent by proper installation and maintenance.

I also wish to call attention to one feature of insert failures not mentioned in your articles; namely, the carelessness on the part of the manufacturer in forming the groove through the insert plate. Failure to have the groove of the insert uniform with the groove of the adjoining rail, especially in curves, is the cause of the gouging of the opposite rail. This is a defect difficult for the railway company to remedy and one to which the manufacturers should give careful attention.

J. H. HAYLOW, Engineer.

UNITED RAILWAYS COMPANY OF ST. LOUIS

ST. LOUIS, MO., Oct. 9, 1914.

To the Editors:

In my opinion the article entitled "A Study of Insert Special Work Failures," appearing in the ELECTRIC RAILWAY JOURNAL of Sept. 19, and the article entitled "Examples of Insert Special Work Failures" appearing in the issue of Sept. 26, cover the subjects very thoroughly. Such articles as these are sure to result in a more thorough study of special work failures by maintenance of way departments. In addition to the study of special work pieces in service, a thorough study of the scrap pile and of the worn-out special work pieces at the time they are removed from the track is worth while.

There is no doubt that the life of insert special work could be materially increased if inserts were tightened, readjusted or removed at the proper time, or if proper work was done with the rail grinder or welder to reduce the pounding of car wheels at cupped places. It has been the practice of this company and, I believe, of almost all of the large companies, to keep one or more gangs constantly engaged in making repairs to insert special work. There is a large variation in the amount of work to be done, however, and it is not always possible to obtain at the proper time a sufficient number of men who are competent to make such repairs. If the work is not handled by well-trained men a large number of inserts are almost sure to become loose in a short time, and even with the best men it is difficult to obtain satisfactory results with some of the types of so-called renewable inserts.

C. L. HAWKINS, Chief Engineer.

The Public Service Commission for the First District of New York has issued Vol. 8 of its proceedings for the period from Jan. 1, 1913, to Dec. 31, 1913. A very complete index at the back of the volume permits a quick reference to any of the cases before the commission during the period.

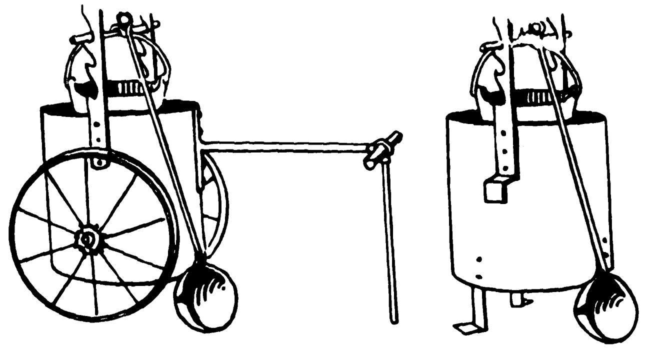
Centers—Renewal and Repair

BY R. P. WILLIAMS, INSPECTOR OF SPECIAL WORK BROOKLYN RAPID TRANSIT SYSTEM

"Get acquainted with your fastenings" is the first word in the care of centers. The maker is always ready to explain their construction. There are many styles of fastenings, and a clear understanding of them will be a big first help. Watchfulness is the next. Examine your centers after a rainstorm, or after the sprinkler has been around; wet lines remaining around the edges of the center show the fastening to be imperfect. If the style of the fastening will permit, tighten it as soon as possible; this will often prevent the loosening of the crossing arms.



FURNACE POT AND LADLE OF PORTABLE AND STATIONARY TYPES

TOOLS

Owing to the variety of fastenings, a full list of tools cannot be given. However, the use and make of the levers and special tools required will be explained and often furnished by the makers of the special work. The chipping tools shown are indispensable. Two styles of lead furnaces are also illustrated; the one on wheels is the better. Before lighting your fire, take the weight off the wheels. To do this we use three short pieces of rail which are 1 in. longer than the distance from the bottom of the furnace to the bottom of the wheels. If the weight is not taken off, the tops of the wheels will soon begin to bind against the side of the furnace. A good grinder is a necessity; flexible shaft types are the most practicable. A good blow torch, also, is needed.

SAFETY FIRST

When chipping, always use goggles with a good heavy glass. "The eye you buy is never as good as the one nature gave you." Always set a block about 6 in. high and 1 ft. wide, with a generous quantity of waste between the block and your chisel; this will protect the pedestrian and incidentally the near-by store windows.

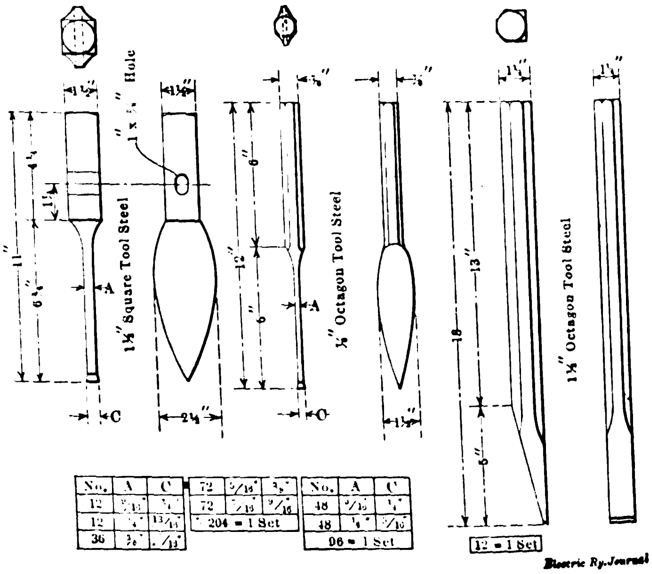
REMOVING THE CENTER

The method of removing the center depends upon the style of fastening. If there is babbitt to remove, you may be able to confine your chipping to one side. Thus clear, you may be able to force your center over to one side, which will give more room to work on the other and allow the use of the heavier cutter. "Stickers" are often met, and the best means we have found to remove them is by expansion. The torch is applied until the entire casting is heated; next a ring of clay or putty about 1 in. high is placed around the center; cold water is then poured on the center, a spillway having been formed to carry the water outside the casting. As soon as the center shows cool, a vigorous attack with light sledges will loosen up the worst "sticker." The operator will quickly become expert at this work, and much time and labor will be saved. The center removed, a thorough cleaning out of all dirt is necessary. To reset for babbitting, all moisture must be removed. The torch is seldom used for this, as kerosene and waste are better and cheaper.

RESETTING

The resetting of the center is the important point and requires quite a little skill. Four points are selected close to the ends of the abutting rails. Then the distance from the top of the rail to the bottom of the bed is found. From this distance deduct the thickness of the center, and the remainder will be the height of the bearing point. Finally, the center is lowered to the tops of the bearing and adjusted until there is a perfect bearing at all four points. It is essential that there shall be no rocking when the fastening is applied.

Opinions differ as to the material for use in the bearing points. We have obtained the best results, under traffic, with soft iron. Some use lead while others use copper. We have found babbitt very good, especially with bolted centers, because the strain can be gradually increased, while lightly tapping the bearing points, until the center is brought to the proper level. The next thing of importance is a good tight end fit. No dependence should be placed on the babbitt for keeping the center tight. A good hard babbitt should be used in order to prevent sagging or giving way in the center.



Electric Ry. Journal

STANDARD CHIPPING TOOLS FOR HARD CENTERS

Babbitt should not be subjected to excessive heat. The practical test of the required heat is made with a piece of dry paper or a sliver of white pine; when the paper or pine flames, your metal is right and should be used quickly for best results.

Pouring babbitt is dangerous work if the proper precautions are not used. A little kerosene in the bottom of the bed will often save a bad burn and can never do any harm. Always use goggles and cover up the top of the hands.

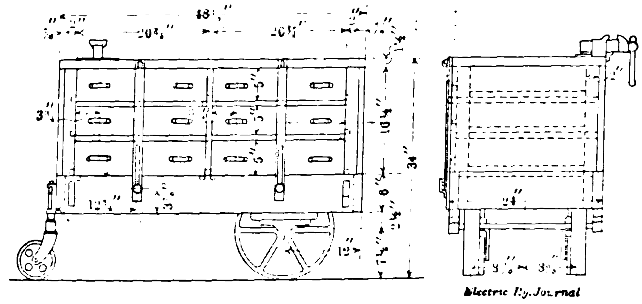
A good emergency repair on an all-babbitt center is made by placing some screen wires or 1/8-in. or 3/16-in. rods in the bottom of the opening, raising them above the floor on small bits of iron, say, 3/4 in. high; place a hammer handle in the groove and pour the opening full of babbitt. The wire prevents the metal from being pounded up to one end, and you will be astonished at the service secured from a center like this. We have had them under fairly hard service for three months and they remained in good shape. They will at least save your crossing while waiting for the new center.

The question of comparative merit between the all-babbitted center, the center with a partly machined bearing surface and the center with a completely machined bearing surface has been raised. No center made will last as long as the crossing (and by this the 90-deg. or nearly 90-deg. crossing is meant) without unduly dishing or becoming so noisy as to make its renewal or repair necessary, but the all-babbitted center, properly installed, will hold just as well as either of the other types. The manner of fastening will not prevent cold rolling or peening; this must be overcome either by direct downward pressure or greater depth of center. This can be done just as easily with the all-babbitt center, with the advantage in its favor of quick renewal and easy fitting.

Detroit United Portable Work Bench

BY C. L. KELLER, ASSISTANT MASTER MECHANIC DETROIT UNITED RAILWAY

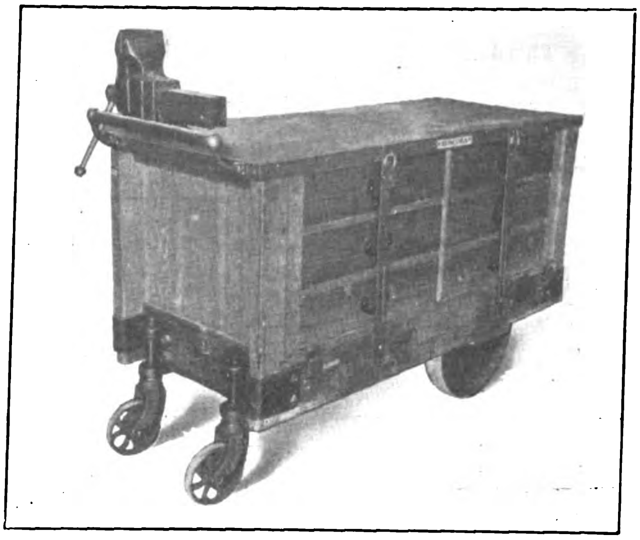
The removal from cars and storage and replacement of the many small brass castings and other parts, prior to painting and finishing, is a process that generally entails numerous petty but annoying losses. Even the loss of time occasioned by the overturn of a box of wood screws or the misplacement of a casting or the running back and forth to a work box may amount to an appreciable period. Therefore, any device that permits work of this character to be accomplished with the least loss of time is always of interest.



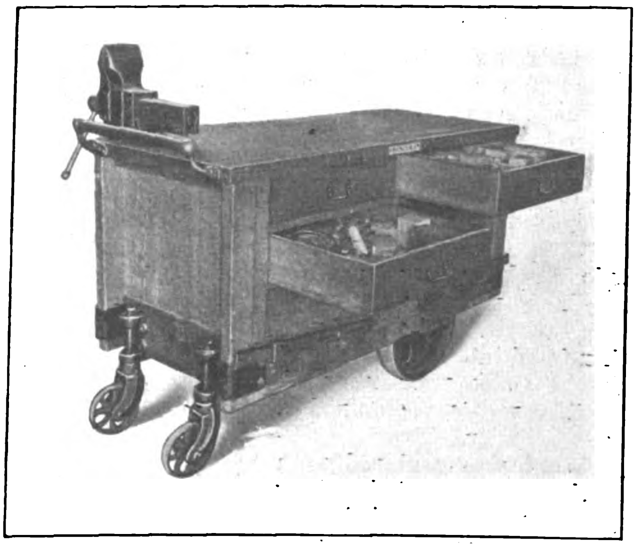
DETAILS OF DETROIT UNITED PORTABLE WORK BENCH

At the Highland Park paint shops of the Detroit United Railway, a portable work bench that deserves comment is in use. This bench is mounted on the familiar type of shop truck and consists of a cabinet 24 in. x 48 in. in plan, containing six drawers. The top of the cabinet is made of 1½-in. oak, and is fitted with a cast-iron woodworkers' vice and a suitable handle for pushing the bench from car to car. The drawers may be locked by means of slotted bars and padlocks, as will be best understood by reference to the accompanying illustrations.

When a workman receives orders to strip a car, he places all the necessary tools in one of the drawers of the bench, and pushes the bench to a convenient location alongside of the car. The several fittings, upon removal, are placed in a drawer reserved for that purpose. When the work is completed, the bench is returned to the stripper's storeroom, where the parts are made into bundles or placed in boxes and tagged with the number of the car. It has been found in practice that two men can work with ease at one bench, and that a number of cars may be stripped before the drawers are filled. Hence only a few trips to the stripper's storeroom are necessary.



PORTABLE WORK BENCH WITH DRAWERS LOCKED



PORTABLE WORK BENCH WITH DRAWERS OPEN

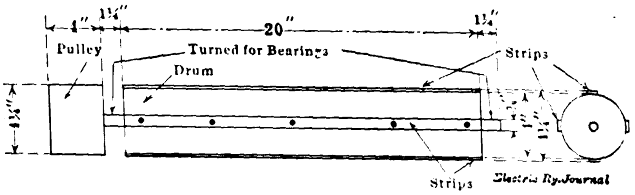
The method of bundling and boxing the fittings eliminates the confusion and chance of loss in the stripper's storeroom, and greatly expedites the cleaning and polishing of these parts. Even the wood screws removed when taking down the trimmings are kept in small boxes provided for that purpose and are used again. When a car is ready for trimming, the drawers of the bench are filled with all the parts belonging to that car, in addition to a supply of extra nails, brads and screws for emergency use. Thus the bench has made it possible to complete the trimming of a car without requiring the frequent trips between car and storeroom formerly necessary. The approximate cost of one portable bench complete is about $40, which is more than made up by the saving of time.

Device for Testing Controller Finger Springs

BY R. H. PARSONS, ELECTRICAL FOREMAN

The Third Avenue Railway, New York, has recently put into use a simple device for testing the springs of controller fingers. This addition was brought about by trouble with broken springs and the fact that certain manufacturers submitted samples of fingers, the springs of which are claimed to be practically unbreakable. To get to the bottom of the situation and to see if there was anything in the claims for unbreakability a device has been fitted up as follows:

A K-11 controller frame then in the shop for overhauling was stripped with the exception of the main cylinder bearings and the fingerboard. An old car axle was mustered into service by turning it to 4 in. in diameter for its full length and also turning it down to 7/8 in. at two points, as shown on the sketch. These points correspond with the bearings of the controller frame, as the turned-up car axle was to fit into the place of the main controller cylinder. The end shown at the left of the sketch was to act as a pulley.



DRUM USED IN CONNECTION WITH A K-11 CONTROLLER FOR TESTING FINGER STRIPS

Four strips 1/3 in. thick x 1 in. wide were screwed onto the drum over its entire length and were equally spaced on its surface. The drum was then fitted into the frame, and the bearings were replaced. In this way we obtained a false cylinder. Next the fingerboard was equipped with the fingers to be tested. These fingers were applied in the usual manner with the regular holding screws, and all were set with the same spring tension. The completed frame was then fastened to a bench, and a belt regulated to run at a speed of 320 r.p.m. was attached to the pulley from the shop line shafting.

The fingers under test are set with 8-lb. spring tension, adjusted so that normally they rest lightly on the drum. As the drum turns, the strips raise the fingers 1/8 in. allowing them to drop to the drum after passing the strip and again lifting when the next strip is reached, thus getting four lifts per revolution of the drum, the action being exactly the same as that received in regular service in a controller.

The diameter of the drum over the strips is the same as that of a main controller cylinder measured over the plates. Therefore the fingers are raised at the same angle as in a real controller, and the lift due to the strips is practically the same as that recommended by the manufacturers of the fingers.

Although not necessary, the standard controller cover is put onto the frame to help keep out the dust and to drown the noise. The drum is well greased with vaseline and is allowed to run continuously. As stated before, the drum makes 320 r.p.m. and as the fingers get four lifts per revolution the fingers will move up 768,000 times during a ten-hour day. It seems to me that this test will decide a number of points about controller fingers.

Proper Connections of Transformer Secondaries to a Self-Starting Rotary

BY J. G. KOPPEL, ELECTRICAL SUPERINTENDENT OF BRIDGES, SAULT STE. MARIE, ONT.

The following incident may be of educational value to the substation construction man:

A substation was erected to house three 500-kw rotary converters with three 185-kw, 25,000-volt, sixty-cycle, single-phase transformers for each rotary. The transformer primaries were connected in delta and the secondaries in six-phase, 428 volts with 61 and 91 per cent starting taps. The rotaries were six-phase, self-starting on the a.c. side, diametrically connected and wound for 600-volt, d.c. railway service.

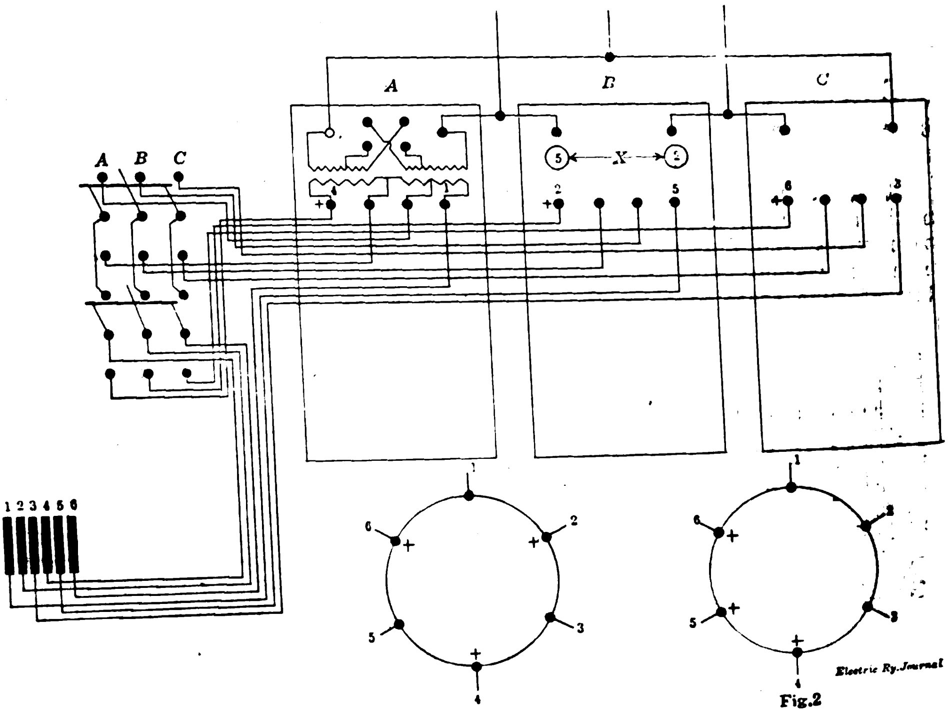


Fig.1 Fig.2

DIAGRAM OF CONNECTIONS BETWEEN TRANSFORMER SECONDARIES AND CONVERTER RINGS WITH ANALYSES SHOWING CORRECT (FIG. 1) AND INCORRECT (FIG. 2) ORDER OF CONNECTIONS

When the rotaries were lined up and the transformer primaries connected I asked the engineer in charge if he had any blueprints of the secondary connections. He answered "No," but gave me half a day to work out the connections from the manufacturer's instruction book. (It should be stated here that the a.c. starting panels and the d.c. panels were supplied by another manufacturer so that we had no assembly print of the connections.) Within the time stated I presented to the engineer the accompanying diagram, which he in turn submitted to the rotary manufacturer's representative for verification before ordering the connection of the secondary cables. But the representative condemned the diagram and ordered us to change the two leads on transformer *B*, indicated by *X* in the accompanying drawing, so that the lead going to ring No. 2 would be transposed to ring No. 5, while the No. 5 lead would go to ring No. 2. The rest of the diagram was pronounced all right.

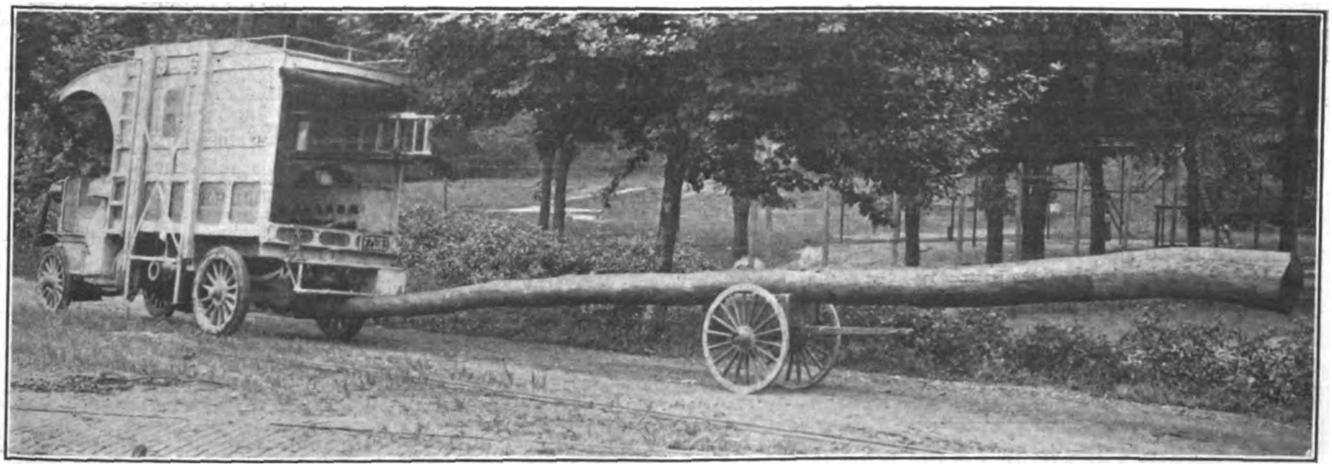
The cables were connected and on the Sunday afternoon set for starting the machinery we tried the rotaries, but they would not run at all although 60 amp at 25,000 volts were being taken from the line. On examination we found that two armature coils of each group of coils were cold but that the third coil was red hot.

We had a long debate as to the cause of the trouble. Some suggested an auxiliary induction motor for starting and others proposed to change the armature. After three days we determined to "cut and try" until the right way was found. Strange to say, when the two leads on transformer *B* were reversed to comply with the original diagram the rotary converter ran correctly. On analyzing the connections we found that the order of positive and negative connections was in alternation as per Fig. 1, whereas the connections suggested by the manufacturer's representatives came out as per the impracticable negative and positive grouping shown in Fig. 2.

When the substation was placed in service the manufacturer's representative was promoted by his company to the position of district engineer. I was dismissed.

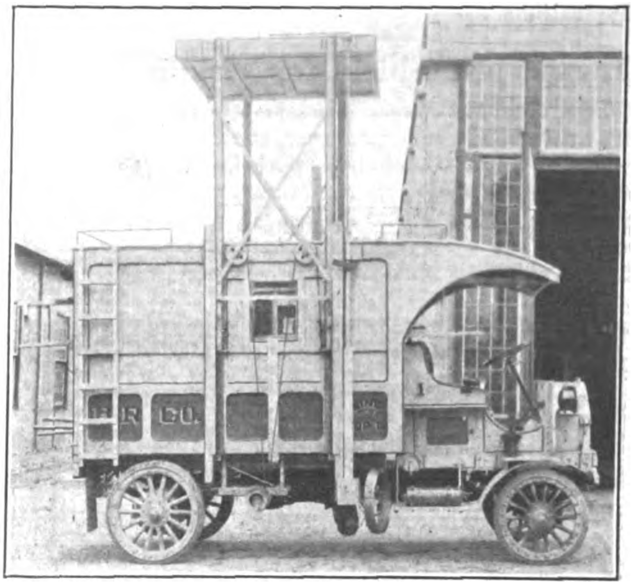
Motor Truck for Line Maintenance

A motor truck for overhead line maintenance embodying a number of unusual features has recently been purchased by the line department of the Harrisburg (Pa.) Railways. Essentially this truck consists of the standard chassis sold by the Motor Truck & Tractor Company, Harrisburg, Pa., equipped with 40-hp, four-cylinder Continental engine and fitted with a body designed especially for overhead line maintenance. This body, exclusive of the driver's seat, is 10 ft. long x 5½ ft. wide over all. The interior of the body, which is reached from the ground by two steps at the rear, is fitted with a work bench, tool box, combination ladder, racks for rope and wire and shelves for miscellaneous tools and buckets. An extension of the upper rear step permits the installation of the pipe vice. A small cabinet on the opposite side of the steps provides space for the soldering kit. This cabinet is substantially built and lined with sheet asbestos so that there will be no liability of fire in case the solder kit is set in it while hot.



HARRISBURG RAILWAY'S LINE TRUCK WITH POLE TRUCK ATTACHED

Perhaps the most novel feature is that the tower platform, which is 6 ft. x 5¼ ft. in size, is raised and lowered by the engine which drives the truck. By means of a worm drive in combination with a friction drive connected to the engine shaft, the tower elevating mechanism is driven by the truck motor. The friction drive is engaged with the engine shaft by a hand lever accessible on the platform floor. This lever is connected to the friction drive by an extension shaft, hence it is operative at any position of the platform. The upper section of this shaft is a rectangular bar which fits into a pipe with a nut bushing at its upper end.



MOTOR TRUCK OF HARRISBURG RAILWAYS WITH MOTOR-DRIVEN TOWER PLATFORM RAISED

The tower elevating shaft projects each side of the car body, where it is fitted with a cable drum. Over these drums two cables pass to a pair of sheaves mounted near the top of the body, and each cable connects to a leg of the tower. The platform legs and guides are of wood and steel construction, being of sufficient length to raise the platform 17 ft. above the ground, thus permitting a lineman to work on a trolley with 22 ft. clearance above the top rail. The platform has folding hand rails on all four sides. A short ladder at one end of the body permits access to the roof, and a small rail around the edges of the roof makes it possible to use this space to store pike poles and other long linemen's tools.

In addition to providing an engine which will propel this truck at approximately 15 m.p.h., the engine was made large enough to draw a pole truck, a coupling being provided for this purpose at the rear end of the body. Views of this truck with the tower in the elevated position, and with the tower down and the pole truck coupled for transportation, are shown in the illustrations.

Inexpensive Shield for Welding Service

To protect the eyes of passers-by when electric welding operations are in progress, the Cumberland County Power & Light Company, operating the electric railway system of Portland, Maine, places around the point the shield illustrated in the accompanying halftone.

The shield is made of car dasher steel 1/16 in. thick and is 30 in. long and 18 in. square at each end. A 3/8-in. round rod brace connects the ends near their outside edges. The force working on the welding job is provided with special goggles, but as a cheap but effective "safety first" device in the interests of the public the shield deserves mention.

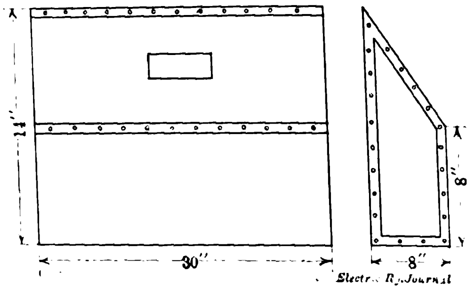
Car Cleaners' Refuse Pan

In order to reduce the cost of car cleaning to a minimum, and at the same time eliminate floor trash which may represent a fire hazard, the master mechanic of the Little Rock (Ark.) Railway & Electric Company has devised and is using a refuse pan of the type shown in the accompanying illustration. This box is made of No. 16 or No. 18-gage galvanized iron, the opening near the top of the apron serving as a handle. The pan was made in the company's shop and its width is governed by the width of the standard step, since it is usually set beside the lower step where the refuse may be swept into it. When the pan is filled it is dumped into a larger trash container located at some convenient point on the carhouse floor.



SHEET METAL BOX

Emergency Kits at Junction Points

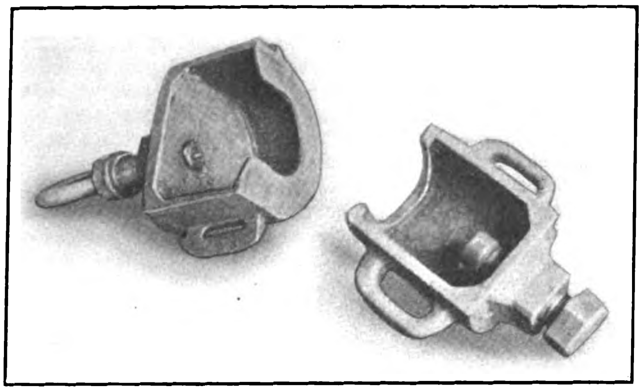
At a great number of junction points on the Minneapolis and St. Paul street railway systems of the Twin City Rapid Transit Company emergency outfits similar to that shown in the accompanying halftone are maintained. These outfits are housed in a wooden box located under the railway's telephone call box. The emergency supplies include trolley pickups, extra switchrods, shovel, broom and such personal belongings like raincoats, rubber gloves, etc., as may be stored there by the local inspectors. A 1-in. steel cable with swivel hooks at each end is stored around the pole holding the box. This cable is available for use in case of derailment or in handling broken wagons.

EMERGENCY TOOL BOX AT JUNCTION POINT

The buses of the Coventry, England, tramways department have been requisitioned by the government for military purposes, and are to be sent to Aldershot.

East St. Louis Pinion Pullers

Generally speaking there are almost as many different kinds of motor pinion pullers as there are shops in this country. Those employed by the East St. Louis & Suburban Railway, while in some respects like others already described, include several features. The pinion pullers shown in the accompanying illustration are used to remove GE-73 twenty-four tooth pinions and GE-70 seventeen-tooth pinions. The castings were made by a local foundry from patterns furnished by the railway. The work of finishing and applying the pulling screws was done in the railway's shops.



PINION PULLERS OF THE EAST ST. LOUIS & SUBURBAN RAILWAY

The smaller puller, or that for the GE-70 seventeen-tooth pinions, is made with a large nut on one end of the puller screw, and the other end is enlarged and cupped so that it will fit over the end of the armature shaft. The other puller also has the cupped puller-screw bearing, but the projection of the screw beyond the nut is formed into an eye. This eye serves as a place to attach the hook from the overhead traveling hoist, which is used to elevate armatures from the pit to the shop floor. A pinion puller of one of these types is provided for each of the different types of motors used by this company. The finished GE-73 puller cost approximately $9, and the GE-70 puller cost about $7 complete.

Testing Dielectric Strength of Oil

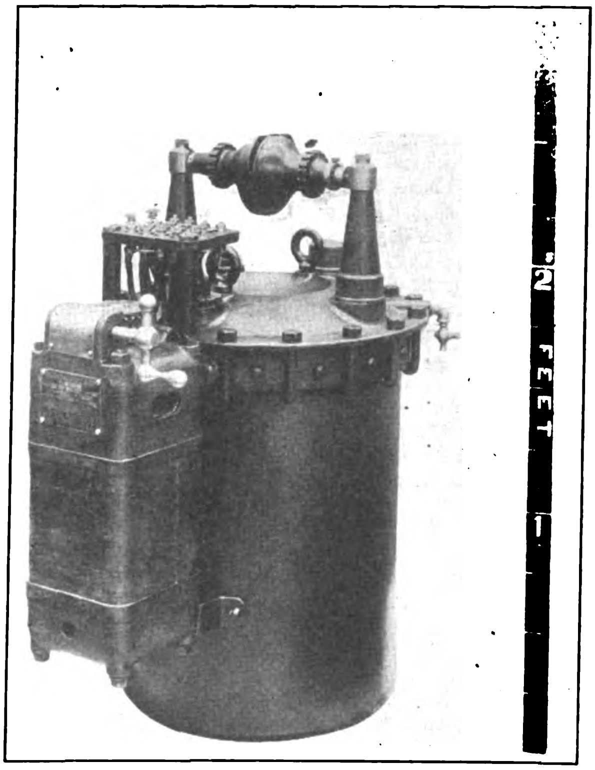
To insure successful operation of high-voltage oil-insulated apparatus, it is necessary to maintain the dielectric strength of the oil at maximum value. A testing set has recently been developed and placed on the market by the General Electric Company for determining this quality.

This set consists of a testing transformer with an induction regulator for voltage control and an oil spark-gap. All of the parts are assembled and mounted to form a compact unit which may be conveniently and quickly operated. The set is built for both twenty-five and sixty cycles.

The transformer has a rating of 3 kva at 30,000 volts, but may be operated at 10 per cent above this figure. The high voltage winding has a voltmeter coil for indicating directly the test voltage. The transformer tank is of drawn seamless steel and the cover is fitted so as to be oil-tight, permitting shipment filled with oil. The induction regulator allows a variation of the test voltage from zero to maximum. The regulator, as well as the transformer, is arranged for series-parallel connection, making the set suitable for use on 100-volt or 200-volt circuits. A dial is attached to the top of the rotor shaft of the regulator and is accurately graduated to give readings of the test voltage directly in kilovolts. The set may also be equipped with a small portable voltmeter for reading the test voltage, provision being made on all outfits for mounting an instrument specially designed for the set. This instrument is of the dynamometer type, is very accurate and the scale is graduated to read the test voltage in kilovolts.

The oil is tested between flat metal disks, which are located inside the receptacle. One electrode is stationary, and the other has a micrometer adjustment with an adjustable zero index. This permits taking up readily any wear in the gap. The receptacle is designed so that it may be very conveniently cleaned. It is estimated that ¾ qt. of oil is sufficient for one sample, allowing five tests on clean oil.

The oil receptacle and spark-gap are supported by the high-voltage terminals of the transformer. Merely by turning the receptacle about its horizontal axis, the oil which has been tested may be emptied, being caught by a depression in the transformer cover and flowing away through a pipe. The receptacle and gap may also be easily removed from the supports, leaving the transformer free for high potential testing of any kind up to 33,000 volts. This apparatus is also equipped with a small sensitive circuit-breaker of novel design, which is attached to the side of the regulator. The set may also be mounted on a truck, making it portable.



TYPE K 30,000-VOLT OIL-TESTING SET

The use of the induction regulator for voltage control produces no noticeable distortion of the emf wave shape and therefore contributes greatly to the accuracy of the test results. The weight of the sixty-cycle set complete is 465 lb., height 30 in., length 24 in., width 17½ in.; the weight of the twenty-five-cycle set complete is 670 lb., height 32 in., length 26½ in., width 20½ in.

An agreement has been reached between the St. Louis, Springfield & Peoria Railway, included in the Illinois Traction System, and the Southern Illinois Light & Power Company whereby the railway agrees to carry freight for the light company in smaller quantities than carload lots. The agreement has been approved by the State Public Utilities Commission of Illinois.

News of Electric Railways

TRANSPORTATION CONDITIONS IN PITTSBURGH

President Callery of Pittsburgh Railways Reviews Transportation Problems in Letter to Mayor

J. D. Callery, president of the Pittsburgh (Pa.) Railways, recently sent to Mayor Joseph G. Armstrong a reply to the Mayor's communication in regard to conditions in Pittsburgh. In his letter Mr. Callery refers to the Mayor's expression of a hope that the company and the city will be able to come to some amicable agreement. He says he reciprocates that feeling, as the company prefers to give good service and to "establish relations of peace and comfort between the city, the company and the latter's patrons." Mr. Callery first replies to the Mayor's apparent implication that the company has not done all it could possibly do to provide good service, then analyzes the Mayor's suggestions, saying some are practicable and others are not, and declares that the service is as good as could be expected "in view of the little aid the company received from the two preceding administrations." Not much can be accomplished, Mr. Callery says, "unless the whole people will give us their intelligent co-operation." The Mayor's recommendations will be carried out, Mr. Callery promises, or else he will show the Mayor that it is not wise that they should be adopted. Concerning the company's treatment of recommendations made by the State Railroad Commission several years ago, the letter makes these assertions:

That on the thirteen routes for which additional service during the rush hours was recommended the service is 44 per cent better; that there are 38 per cent more street inspectors to regulate the headway of cars that the schedule may be followed; that there are no more switches in the downtown district that have to be operated by the crew of a car; that the heating and ventilation of cars are better regulated and are in charge of the crews; that the company has shown itself ready to co-operate in the abolition of grade crossings; that 308 double-truck cars have been put into service instead of only the fifty additional fixty-six-seat cars recommended by the commission in June, 1910; that in trying to improve the service and to change the number of cars to suit the requirements of travel the company is at a disadvantage in that there are some lines which do not have places at the termini where cars can be turned, and therefore a few lines do not furnish as good a service as they otherwise could; that many of the twenty-eight-seat cars have been abandoned, as recommended, and replaced by larger cars.

Several reasons against through routing of cars are given. Regarding the suggestions by the Mayor for a more liberal transfer system, Mr. Callery says:

"A universal transfer system in such a city as Pittsburgh would not be just to the company. You do not suggest such a system in your letter, nor do I believe that you would think of demanding it. There must be some proportion established between the distance the passenger travels and the 5-cent fare. Every patron will recognize that there is some mileage which he is entitled to for 5 cents, and he ought not to ask for more, nor would he if he thought he was justly treated. We are limited to a fixed fare of 5 cents within the city, and every passenger coming into town in the morning or going home at night gets an equivalent for what he pays. Short riders do not proportionately get as much as the passenger who is carried 4, 5 or 6 miles, but we do not like this any better than the short rider does. It is impossible in street-car traffic to make each passenger pay exactly the mileage he travels, as in railroad traffic. It would take too much time to adjust it on the cars. The London bus system could not be applied to street cars.

"Every district of the county has its own through service into the city. This is due largely to the topography. Street cars have to follow the easiest route. There are sixty-six distinct lines that touch the downtown district. We cannot construct and operate crosstown routes with any advantage. It has been our aim and purpose to bring every passenger into the heart of the city for one fare. We have tried to select transfer points so that men and women may get to and from working centers for one fare.

"It is not to the particular advantage of the people of the city to give universal transfers, but rather to the suburban patrons who get a long ride anyway. To give to a patron of one distinct route a transfer which would let him ride to the end of the other sixty-five routes would be folly. There is no way by which we can get money to run the cars except through the 5 cents from our patrons. A general transfer system would give to those persons who may now get a long ride a still longer one, and the person who really pays his own fare and a little more for the suburbanite would have poorer service.

"I have felt it my duty to state my objections to some of your suggestions, but I wish you to understand from this letter that I am ready to do anything that is practicable in the way of adopting any of the changes and recommendations of yourself and of the City Council. There is no one who is more anxious than I to have the Pittsburgh Railways give the best possible service to the public."

A list of suggestions for new franchises is appended to Mr. Callery's letter, the proposed grants including curves, turnouts, sidings and new tracks on streets already occupied by rails and on streets not yet occupied.

DEVELOPMENTS IN CLEVELAND

New Stock Issue, Schedules and Safety Zone Matters Reviewed

The Cleveland (Ohio) Railway has applied to the Ohio Public Utilites Commission for permission to issue $2,382,600 of new stock. Councilman William Stolte and others objected at once on the ground that the low fare would be endangered by the additional stock issues. Mayor Baker, however, notified the company that the city would make no opposition. He said that the place to oppose expenditures is in the City Council and not before the commission. E. W. Doty, a member of the commission, said that a hearing on the application would be held shortly. Joseph Alexander, engineer, of the street railway commissioner's office, said that all the expenditures shown in the application were favored by Commissoner Witt.

Councilman Koch introduced a resolution at the regular meeting of Council on the evening of Oct. 5 which provides for a 4-cent fare with a rebate of 1 cent for transfers. Mayor Baker, however, disapproved of the plan. Mr. Koch insists that it is unfair to force those who are compelled to use transfers to make up the deficits in operation. W. F. Thompson, president of the City Council, revived the idea of the zone system. He says that it is practically impossible to extend the 3-cent fare system to outlying territory and that a readjustment of the plan must be made at no distant date.

J. J. Stanley, president of the Cleveland Railway, stated that the company would insist upon the schedules in the Tayler franchise, and that it would be unwise to try to undo what has been done and introduce another period of trials and uncertainty.

Cleveland is experimenting with a safety zone system similar to that in use in Detroit. At two Superior Avenue crossings and at the car stop on the east side of the Public Square zones have been marked off with paint on the pavements, and police officers have been stationed to instruct both pedestrians and drivers of vehicles how to use them. Safety lanes 25 ft. wide have been marked from curb to curb at the crossings and a strip 60 ft. long and 6 ft. wide has also been marked off at each car stop. This space is known as the safety strip. No vehicle is allowed to drive inside of this strip.

W. R. Hopkins, president of the Cleveland Rapid Transit Company, announced on Oct. 5 that all arrangements had been completed to finance the underground railway which the company proposes to build in Cleveland. The time for commencing the work will depend upon the breaking of the financial deadlock caused by the European war.

Members of the Cleveland local of the Amalgamated Association of Street & Electric Railway Employees are endeavoring to have a legislative committee established by the appointment of one member from each local organization in the State. They feel that the Legislature should collect the laws pertaining to the electric railway men and include them all in one bill, so that they would have no trouble in understanding just what is required.

NEW YORK SUBWAY CONSTRUCTION CONTRACTS

Recent Work Under Way and Contracts Let

Work has begun on the construction of the two new rapid transit tunnels under the East River from downtown Manhattan to Brooklyn. The two tunnels will be built by the Flinn-O'Rourke Company, Inc., and will cost more than $12,000,000. One will be operated by the Interborough Rapid Transit Company, and will connect the Seventh Avenue subway in Manhattan with the existing subway and its extensions in Brooklyn, the tunnel leaving Manhattan at Old Slip and reaching Brooklyn at Clark Street. The other will be operated by the New York Municipal Railway Corporation as a connection between the Broadway subway in Manhattand and the Fourth Avenue subway system in Brooklyn, the tunnel leaving Manhattan at Whitehall Street and reaching Brooklyn at Montague Street. The contract time for the completion of the tunnels has been set at forty-two months.

The Public Service Commission has awarded the contract for the construction of the diagonal station and connection in Forty-second Street between the existing subway and the new Lexington Avenue subway. It went to the lowest bidder, the Rapid Transit Subway Construction Company, for $3,097,312. This is the construction company of the Interborough Rapid Transit Company, the lessee of the existing subway. This connection will pass under the old Grand Union Hotel property and diagonally across and under Forty-second Street and a portion of the New York Central property on the northwest corner of Lexington Avenue and Forty-second Street. The diagonal station will be built in front of the Grand Central Terminal in Forty-second Street. It will be one of the largest underground stations in the world, and will have connections with the Grand Central Station, the proposed extension of the Hudson & Manhattan tunnels, the existing subway, the new Lexington Avenue subway and the reconstructed Steinway tunnel. Considering its location and the number of lines which will reach it, this station will probably develop into the greatest traffic center in New York City. As the construction must be done without endangering or seriously interfering with traffic in the existing subway, the contractor is required to give a bond of $250,000 to the Interborough Company, the lessee of the subway, as well as a bond of $500,000 to the city, for the faithful performance of the work.

Bids have been opened for that part of the Park Place, William and Clark Street subway, which runs from the Seventh Avenue subway in West Broadway through Park Place. under the Post Office Building and Beekman Street to William Street. This is part of the route which will connect the new Seventh Avenue subway with the new tunnel to Brooklyn, and will be operated by the Interborough Rapid Transit Company. It will be a two-track line, with a local staion at Park Place and Church Street, having an entrance from Broadway. It will pass under the new Broadway subway as well as the existing subway in Park Row. The official figures on the bids submitted were as follows: Frederick L. Cranford, Inc., $1,571,363; Degnon Contracting Company, $1,714,200; Smith, Hauser & MacIsaac, $1,886,467; Holbrook, Cabot & Rollins Corporation, $1,967,471; Oscar Daniels Company, $1,975,732; Underpinning & Foundation Company, $2,049,098; Rapid Transit Subway Construction Company, $2,250,175.

At its meeting on Oct. 6 the Public Service Commission refused, by a vote of four to one, to adopt a resolution, offered by Commissioner J. Sergeant Cram, declaring forfeited a contract between the city and the Dock Contractor Company for the construction of that section of the Broadway subway, Manhattan, lying between Bleecker Street and Union Square.

The Public Service Commission has approved the award by the New York Municipal Railway Corporation to the Thomas Crimmins Contracting Company for $197,442 of the contract for the installation of the third-rail, etc., in the Fourth Avenue subway, Brooklyn, between the Manhattan Bridge and Eighty-sixth Street. The proposed installation involves approximately 141,300 ft. of third-rail and 126,800 ft. of track rail bonding. The company will furnish the third-rail and most of the other materials. The contractor will give a bond of $25,000, and will agree to complete the work within thirty days from the completion of the track-laying work by the city, which is being done by the Thomas Crimmins Contracting Company.

The Public Service Commisson has approved the award by the New York Municipal Railway Corporation to the Terry & Tench Company, Inc., the lowest bidders, for $321,305 of the contract for the construction of additional tracks on the Broadway elevated line in Brooklyn between Havemeyer Street and Myrtle Avenue. The company will supply the structural steel, ties and other materials to be used in the installation of the additional tracks, and the contractor will perform the work. The plans have been submitted to the commission and approved by its chief engineer.

NEW SOUTH WALES GOVERNMENT RAILWAYS AND TRAMWAYS

According to the report of the Chief Commissioner, the number of tramway lines of the New South Wales Government Railways & Tramways open on June 30 was 212. The total capital expenditure on these lines was £7,628,653. The expenditure charged to capital account during the year amounted to £929,348. The total earnings were £1,934,164, as compared to £1,754,566 during the preceding year, an increase of £179,598, or 10.23 per cent. The working expenses amounted to £1,669,033, as compared to £1,572,190 for the preceding year, an increase of £96,843, or 6.16 per cent. The percentage of expenditures to receipts decreased from 89.61 per cent to 86.29 per cent. The net surplus, after providing for working expenses and interest on capital, was £1,680, as compared to a deficit of £32,456 last year. During the year the tramway fares were increased and it is estimated that the extra revenue secured during the last three months amounted to £45,000, thus enabling the company to wipe out the deficit that had accrued to the company during the preceding year.

During the year 310,592,698 passengers were carried, as compared to 294,455,452 during the preceding year, an increase of 16,137,246. The tramway miles run increased 1,460,709 to a total of 28,415,476. During the year 138 eighty-passenger bogie motor cars and thirty-two fifty-passenger four-wheel motor cars, besides other equipment, were purchased and 516 electric cars were overhauled. The earnings per tram mile increased from 1s. 3½d. in 1913 to 1s. 4¼d. in 1914. The working expenses showed no change in percentage, so that the return per tram mile after paying working expenses increased from 1½d. to 2¼d. The total staff during the year was 42,721, of which the tramways employed 9,394.

LAST OF TRUST LEGISLATION

The House of Representatives has now adopted the conference report on the Clayton anti-trust bill, following similar action by the Senate. The enactment of the Clayton bill into law ends the adminstrative program in respect to trust legislation, at least as far as the present moment is concerned.

Representative Mann, minority leader of the House, spoke in opposition to the adoption of the report, although he was not supported by all the other Republicans on the vote. Twenty-two Republicans stood with the solid Democratic majority as in favor of the legislation, and six Progressives also voted with the Democrats. The vote was 244 for and fifty-four against.

In attacking the Clayton bill report, Representative Mann pleaded for a cessation of legislation affecting business, saying: "We have the opportunity now by wise legislation to encourage our people to build manufacturing institutions, to make America independent practically of foreign aid in commerce, and to give us an inlet into every foreign commerce with our manufactured articles. We ought to be encouraging the production in our own country of many articles for which we are now wholly dependent upon foreign lands."

Joplin Arbitrators Chosen.—James A. Cable has been selected by the employees of the Joplin & Pittsburgh Railway and John M. Kinkel by the company as members of the board of arbitration to consider the wage schedule, which will automatically become a part of the agreement signed recently. These two will select the third arbitrator. Both Mr. Cable and Mr. Kinkel are members of the Kansas Public Utilities Commission.

Transportation Hearings for Western Massachusetts.—The commisson appointed by Governor Walsh to investigate the transportation needs of the five western counties of Massachusetts will shortly begin public hearings at the Hampden County Court House, Springfield. Among the subjects to be considered is the future electric railway development of the district. A strong sentiment on behalf of additional lines exists in many of the Berkshire towns, but no satisfactory plan of financing these has come to the front since the plans of the New York, New Haven & Hartford Railroad for the development of the district had to be abandoned for the time being.

Obstructionist Measures Laid on Table in City of Toledo.—At a meeting of the committee on public offices of the City Council of Toledo, Ohio, on Oct. 7, Councilman Mulholland's resolution to have the franchise committee break off all negotiations with the Toledo Railways & Light Company and with the various civic organizations was laid on the table. The committee took the ground that such a step would be antagonistic to every one interested in the speedy settlement of the franchise question. Council met in regular session on Oct. 5, and after adjournment the franchise committee discussed the Kryzaniak resolution to employ Cornell Schreiber, former city solicitor, to aid the law department in its contest with the railway company. This matter was finally tabled indefinitely. The majority of the members felt that City Solicitor Thurstin and his assistants are able to handle the matter and that data or information secured by Mr. Schreiber during his term in office belongs to the city and should be turned over to the law department.

New York Commission Disposing of Accumulated Business.—All cases pending since before the present personnel of the Public Service Commission of the Second District of New York assumed office have now been assigned for determination, and current cases are disposed of, in addition, as rapidly as may be. During the last month fifty-nine new formal cases were filed with the commission, but as final orders were issued in sixty-six cases the pending total has been reduced from 287 to 280. This makes a total of 363 new cases filed since March 16 of this year, and a total of 473 finally disposed of, reducing the number of cases pending from 390 on March 16 to 280 on Oct. 1. The disposition of informal complaints has kept pace with those of formal character. More than 125 informal complaints have been disposed of during the last month and eighty-four new ones filed. This reduces the total of such cases pending on Sept. 1 from 375 on that date to 331 on Oct. 1. Since March 16 more than 850 informal complaints have been filed with the commission and 1087 have been disposed of, reducing the total pending before the commission from 558 on March 16 to 331 on Oct. 1.

PROGRAM OF ASSOCIATION MEETING

Kansas Gas, Water, Electric Light & Street Railway Association

The seventeenth annual convention of the Kansas Gas, Water, Electric Light & Street Railway Association will be held at the Fifth Avenue Hotel, Arkansas City, Kan., Oct. 22, 23 and 24. The program includes the following papers: "Co-operation," by H. W. McGruder, president of the Liberal Light, Ice & Power Company; "Cost of Distribution and Overhead Charges," by E. A. Wright, manager of the Manhattan Light, Ice & Power Company; "Regulation and Control of Public Utilities," by T. J. Strickler, engineer of the State Utilites Commission, Topeka; "Safety First," by A. M. Patton, assistant general manager of the Western Railways & Light Company, Topeka; "Rate Making," by Prof. George Shadd, Kansas University, Lawrence; "When Bonds Come Due," by H. P. Wright, president of the H. P. Wright Investment Company, Kansas City.

Financial and Corporate

Havana Electric Railway, Light & Power Company

The condensed profit and loss statement of the Havana Electric Railway, Light & Power Company, Havana, Cuba, for the year ended Dec. 31, 1913, follows:

Gross earnings	$5,417,054
Operating expenses	2,489,832
Net earnings from operation	$2,927,222
Interest on deposits, rents, etc	140,087
	$3,067,309
Fixed charges, taxes, etc	1,219,206
Surplus income for the year	$1,848,103
Acquired surplus*	856,810
Surplus Jan. 1, 1913	294,749
Total	$2,999,662
Deduct:	
Dividends paid during the year	$1,686,205
Profits transferred to sinking fund reserve	92,412
Total	$1.778,617
Profit and loss balance carried forward to 1914	$1,221,045

*Acquired surplus represents excess in dividends received on stock of the Havana Electric Railway during the year from its accrued surplus over its actual earnings for 1913.

The above statement includes the operations of the railway division of the company only from June 18, on which date the operation by the Havana Electric Railway ceased upon its legal dissolution by merger into the Havana Electric Railway, Light & Power Company. The statement of operation of the railway division for the year, including the operation by the Havana Electric Railway to June 18, 1913, is shown by the following statement:

Car earnings	$2,860,947
Miscellaneous earnings	48,286
Stage earnings	356,894
Gross earnings	$3,266,127
Operating expenses:	
Maintenance	$322,041
Transportation	931,325
General	173,606
Stage lines	284,685
Total	$1,711,657
Net earnings from operation	$1,554,470
Deduct:	
Interest	$462,744
Taxes	61,601
Total	$524,345
Net income*	$1,030,125

*Miscellaneous income, such as interest on deposits, etc., not strictly departmental not included.

At the end of 1913 the railway department was operating twenty-four lines with a maximum of 285 cars on week days and 289 on Sundays. The total number of fare passengers was 56,782,362, an increase over 1912 of 4,913,509, or 9.47 per cent. The increase in 1912 over the preceding year was 7.1 per cent. The passenger earnings of the entire system during 1913 were 9.47 per cent in excess of the earnings for 1912. The passenger car miles increased from 9,192,296 in 1912 to 10,543,739 in 1913, or 14.7 per cent. Passenger earnings per car mile decreased from 0.2822 cent to 0.2693 cent, or 4.57 per cent. The total operating expenses increased 8.84 per cent, while the total operating expenses per car mile decreased from 0.1426 cent to 0.1353 cent, or 5.12 per cent.

The total new construction for single track, exclusive of yards, for 1913 was 5.53 miles, giving a total mileage of 71.78 miles. There were 4.68 miles of trackage reconstructed in 1913. Fifty new closed motor passenger cars were constructed and equipped and nineteen passenger cars were reconstructed. All new passenger cars were equipped for single-end operation and the older cars are being gradually changed from double to single end. The stages owned by the company decreased from 168 in 1912 to 165 in 1913, and the gross receipts decreased from $390,002 to $356,894. It is stated that preparations are being made for the use of electric motor omnibuses to replace a portion of the present stage service.

The work of maintaining discipline among the employees through the decision of a jury of two men, selected from conductors and motormen who serve for a period of four months, has been in use, it is stated, continuously since the latter part of 1907 with increasing success. During 1913 this jury examined and passed upon 10,038 cases, out of which 6094 were warned, 2159 fined, 1541 suspended, 125 discharged and 12 ordered back to practice. During the year 170 men resigned.

Accidents involving personal injury have shown a steady relative decrease during the last six years, owing to the effect of the jury system, the improved organization and the distribution of cash prizes to car men with best accident records. The car miles per accident have increased 50 per cent as compared with 1908 and the total passengers per accident 70 per cent. During the year a total of 19,134 trips were lost owing to wagon blockades. Freight traffic required 44 per cent more locomotive hours and 85 per cent more car hours. The total freight car mileage amounted to about 4.5 per cent of the passenger car miles.

Winnipeg Electric Railway

The income statement of the Winnipeg Electric Railway, Winnipeg, Man., for the year ended Dec. 31, 1913, follows:

Gross earnings	$4,078,694
Gross expenses	2,252,606
Net earnings	$1,826,088
Fixed charges	$570,583
Dividends	1,070,043
	$1,640,626
Surplus for year	$185,462
Balance Dec. 31, 1912	2,091,236
	$2,276,698
Less transfer to reserve account	$1,000,000
Less transfer to suspense account	375,000
	$1,375,000
Balance Dec. 31, 1913	$901,698

The gross receipts of the company for 1913 were $4,078,695, as compared to $3,765,384 in 1912, an increase of $313,311, or 8.32 per cent. The operating expenses for the two years were $2,252,607 and $2,004,142, an increase for 1913 of $248,459, or 12.4 per cent. The net earnings of $1,826,088 for 1913 compared with $1,761,236 for 1912, an increase of $68,852. or 6.8 per cent. The operating ratio increased from 53.23 in 1912 to 55.23 in 1913. Passengers carried in 1913 were 59,563,757 and in 1912 51,106,017, an increase of 8,457,740. Transfers increased from 11,858,213 in 1912 to 15,039,016 in 1913.

After providing for the percentage on earnings accrued to the city and the interest of bonds, the directors declared four quarterly dividends amounting to $1,070,043. This left a surplus of $185,462 to be transferred to profit and loss, making a total credit as of Dec. 31 of $2,276,698. From this $1,000,000 was transferred to the reserve account and $375,000 to the expense account, leaving $901,698 to be carried forward to profit and loss.

During the year 18.147 miles of track were laid and forty double-truck closed motor cars were constructed in the company's shops. During the period the company was granted a franchise and made contracts for new railways in the municipalities of St. Vital and Fort Garry.

GLASGOW CORPORATION TRAMWAYS

The result of the operations of the Glasgow Corporation Tramways for the year ended May 31, 1914, shows that the ordinary income amounted to £1,083,846 and the working expenses to £676,277, leaving a net revenue of £407,569. The ordinary income of the previous year was £1,011,543 and the working expenses £619,346, leaving a net revenue of £392,196. After adding interest on investments and rental of lines, and after deducting interest, sinking fund, taxes and depreciation and expenses amounting to £418,666, the net balance of £53,892 was paid over to the Common Good. The average traffic revenue per car mile increased from 10.364d. to 10.609d., or 0.245d. The working expenses, however, increased 0.281d. per car mile, mainly on account of increased wages, extra expenditures for permanent way and maintenance, fuel costs and local taxation.

The total amount of expenditure on capital account as of May 31 was £3,675,317. The amount to the credit of the depreciation and permanent way renewals fund at the beginning of the year was £2,040,282. There was added during the year £212,642 and deducted for renewals £94,186 of the account, leaving a credit balance of £2,158,738. To the original credit in the general reserve of £39,362 there was added £113 and deducted £1,405, giving a credit balance of £38,069. During the year £77,797 was expended for ordinary tramway repairs. In addition to this £85,438 was set aside to meet the cost of track renewals, calculated at the rate of £440 per mile of single track. The total cost of ordinary repairs for the power plant and sundry machinery was £7,895, and the charges against revenue to meet depreciation amounted to £32,048. The total cost of maintenance on miscellaneous equipment was £1,426 and revenue charges for depreciation £3,714. The total length of tramways now owned by the corporation, measured as single track, amounts to more than 196 miles.

Camden & Suburban Railway, Camden, N. J.—The Camden County Board of Equalization of Taxes, acting upon suggestions of the New Jersey Board of Equalization of Taxes, recently made increases aggregating $500,000 for public utility corporations in Camden. The equipment of the Camden & Suburban Railway, operated by the Public Service Corporation of New Jersey, was raised in valuation from $231,000 to $346,000, and the value of the poles and wires of the company was increased from $150,000 to $225,000. The gas equipment of the South Jersey Gas, Electric & Traction Company, also operated by the Public Service Corporation of New Jersey, was increased in valuation from $231,000 to $347,625.

Cleveland (Ohio) Railway.—The Cleveland Railway has applied to the Public Utility Commission of Ohio for authority to issue $2,382,600 of additional capital stock.

Interurban Railway & Terminal Company, Cincinnati, Ohio.—The Interurban Railway & Terminal Company, the property of which was placed in the hands of receivers recently, suffered severely from the floods last year and from fire which destroyed its Sycamore Street depot in Cincinnati and a fire which destroyed another depot. The suit by the city to force the company to carry passengers to the city limits for a 5-cent fare complicated matters still further.

Lisbon (Portugal) Electric Tramways, Ltd.—The result of operations of the Lisbon Electric Tramways, Ltd., for the year ended Dec. 31, 1913, after deducting interest and amortization due on the debentures of the Compania Carris de Ferro de Lisboa and after the payment of £25,650 for interest on and redemption of the debentures of this company and also paying office expenses and directors' fees, showed a net profit of £103,686. Added to the £1,637 brought forward from the preceding year this gives a balance of £105,323. Of this amount £35,000 was credited to the depreciation reserve and £5,000 to the exchange reserve account, there remaining an available balance of £65,323 from which the usual preference dividend amounting to £25,533 was paid. On the ordinary share capital an interim dividend of 3 per cent, amounting to £19,020, was paid in November, 1913, and a final dividend at the same rate has been recommended. The balance of £1,749 was carried forward to next year's account.

New England Investment & Security Company, Springfield, Mass.—According to a statement filed with the Massachusetts Public Service Commission by the New England Investment & Security Company for the year ended June 30, the dividends and interest received during the year amounted to $712,215; deductions, $24,173; interest on coupon notes, $445,543, and dividends $170,000, leaving a surplus for the year of $72,499. This, combined with the accumulated deficit on June 30, 1913, of $525,717 and the discount on the sale of bonds of $23,920, gives a total deficit as of June 30, 1914, of $477,138.

Northern Electric Railway, Chico, Cal.—Meetings of the bondholders and other creditors of the Northern Electric Railway were called for Oct. 13 and 14 by the trustees of the Sloss Security Company to consider a reorganization plan.

Philadelphia & Western Railway, Upper Darby, Pa.—The gross earnings of the Philadelphia & Western Railway for the year ended June 30, 1914, were $371,857, as compared to $297,061 for the year previous. The operating expenses increased from $174,697 in 1912-1913 to $208,377 for the present fiscal year. The net earnings increased from $122,364 to $163,480; taxes from $10,459 to $11,100; other deductions from $1,023 to $1,065, and interest from $112,617 to $136,940. The surplus account increased from a deficit in 1912-1913 of $1,735 to a surplus of $14,375 for the last year. The company now operates 38.05 miles of track and owns twenty-seven cars. The capital stock authorized and outstanding is $2,000,000 of preferred and $4,000,000 of common. The authorized bonded debt is $4,000,000, of which $3,000,000 is outstanding. Of this amount, $970,000 is in the treasury of the company. A summary of the history of this company was published in the ELECTRIC RAILWAY JOURNAL of July 18, page 145.

Public Service Railway, Newark, N. J.—The $300,000 of Paterson Railway second general mortgage 5 per cent bonds due on Oct. 1, 1914, are being taken up on presentation at the office of J. S. Rippel, Newark, N. J. Holders on paying $10 per bond may have the security extended for thirty days at 5 per cent.

United Railways, St. Louis, Mo.—James D. Mortimer, president of the North-American Company, has been elected a director of the United Railways to succeed the late James Campbell. Richard McCulloch, who has been vice-president and assistant general manager of the United Railways, has been appointed general manager to succeed his father, the late Capt. Robert McCulloch. No successor has been elected to Capt. McCulloch as president.

DIVIDENDS DECLARED

Brooklyn (N. Y.) City Railroad, quarterly, 2 per cent.

Havana Electric Railway, Light & Power Company, Havana, Cuba, 3 per cent, preferred; 2½ per cent, common.

Milwaukee Electric Railway & Light Company, Milwaukee, Wis., quarterly, 1½ per cent.

Public Service Investment Company, Boston, Mass., quarterly, $1.50, preferred.

Traffic and Transportation

TRAINMEN'S MEETING AT LAWRENCE

So-Called War Meeting Held Recently to Discuss the Item of Expense, the Enemy Against Gross Receipts.

It is the practice of the managers of the various properties controlled by the Albert Emanuel Company, Dayton, Ohio, to hold meetings of the trainmen every week. At Lawrence, Kan., a so-called war meeting was held recently. The men were addressed by J. T. Skinner, manager of the Lawrence Railway & Light Company. This meeting was particularly fruitful in results and provoked considerable discussion. An abstract of Mr. Skinner's remarks follows:

"We will call this our 'war meeting,' simply making use of the latest issue as a synonym. Our work is to give efficient service at the lowest possible expense. A war council has for its object consideration of the best methods of attacking the enemy. We are together to consider plans for attacking the items of expense, our enemy against our net receipts. This does not mean that we have not appreciated your efforts in carrying on this war against expenses, but it does mean an attack with renewed energy against unnecessary expense. As we have no desire to cut down the service or throw men out of employment, it is up to us to see if we cannot, by our 'safety first' movement and courteous treatment of the public, increase receipts and decrease operating expenses so that our net receipts shall be greater and the capital invested in the property feel less like going on strike. We hope each will enter into the spirit of the movement and do cheerfully whatever extra work may be involved. You men can easily note the attitude of the people. We are giving the equivalent or better service than four years ago. On three recent Sunday evenings we had fully as many at the park as when the resort was new, but the receipts were from $60 to $100 less than formerly. People walk out, get all they can free and walk back.

"The main thing in connection with our expenses is the question of accidents. 'Safety first' comes ahead of good service and courteous treatment. You have more to contend with than you did four years ago. While four years ago we had about 100 automobiles, two weeks ago the number registered with the county was 469 and there were fully thirty more that had not been registered. Good paving and long blocks tend to encourage the speeding of automobiles and motor cycles. In this 'safety first' campaign we want the co-operation of the automobile owners and drivers. If you men are not careful, it will do very little good to put 'safety first' slogans in the cars and publish articles in the papers. The men in our organization must be the leaders in the 'safety first' campaign against accidents. The cards in the cars, the articles in the newspapers and the blotters given to the school children all tend to help this movement.

"Accidents are always costly. Even if no damage is done, service is delayed and time and expense are involved in making investigations. It is up to you to get as accurate and thorough a report on the spot as possible. In connection with accident cases the tendency has grown on the part of the public to file claims for an amount which they think does not justify the expense on the part of the company of making a thorough investigation and contesting the case. The best way to deal with the matter is to prevent accidents from occurring, or at least cut the number down to a minimum. We cannot pay you men a 1 per cent dividend if our receipts continue to decrease and our expenses to increase. We must earn that dividend by saving it in our operating expenses. Watch the little things.

"The 'safety first' movement depends more on the spirit with which it is entered into than on the actual equipment, devices or methods employed. Another feature of the 'safety first' movement is concentration. Concentration presupposes that you can keep your mind on what you are doing and not worry about other conditions. In running your car have your mind on your work. There are many things that cause a man to worry, but by keeping them out of your mind while you are on duty you make your own work easier, with better results for the company and for yourself.

"In this 'safety first' movement we have placed fourteen safety slogans in the cars. We want more. We want your assistance in helping to work up safety slogans that will add interest to the campaign and be of benefit to you and to the company. We are going to make small rewards for safety slogans handed in. Mr. Rice will act as judge. We figured on offering prizes of 50 cents each for the ten best 'safety first' slogans and 25 cents each for all other 'safety first' slogans that we accept. We will not know nor will Mr. Rice whether the whole prize will go to one man or be divided among ten."

In the general discussion which followed the men told their experiences. The feeling was that the automobilist of to-day is more careless and causes more trouble than did the operators of cars four years ago. The new traffic ordinance was also considered, and it was agreed that respect for the measure could be secured best by the trainmen themselves paying strict and constant obedience to every provision of the ordinance.

Gasoline-Electric Bus Service for Springfield, Mass.—Regular electric motor bus service will shortly begin at Springfield, Mass., under the auspices of the Springfield Transit Company, between the downtown district and the Forest Park section of the city. The equipment consists of a bus seating twenty-eight passengers and driven by a 15-kw gasoline-electric-generator unit supplying energy to a 25-hp motor. The company contends that with a 10-cent fare the service will be more flexible than can be afforded by the local trolley system.

Service Problems in Cincinnati.—At a meeting of the committee on transportation of the Federated Improvement Association of Cincinnati, Ohio, on Oct. 8, a report of its investigation into the street-railway service was made. While a communication was sent to the City Council asking that steps be taken to furnish the kind of service people want, it was explained that Walter A. Draper, vice-president of the Cincinnati Traction Company, had informed the committee that the transfer and rerouting plans were now in process of adjustment between the Council and representatives of the company.

Authority of Pennsylvania Commission Over Boroughs.—S. H. Mountney, general manager of the Slate Belt Electric Street Railway, Pen Argyl, Pa., recently complained that the action of the borough of Pen Argyl in refusing to permit cars to stand on tracks at terminal points frequently resulted in patrons missing desired connections. The commission in dismissing the complaint wrote in part as follows: "Speaking generally, this commission would have no authority under the act of Assembly to issue any orders against boroughs, since they are not public service companies within the meaning of the Public Service Company Law. Such boroughs are vested with certain authority over the use and occupation of the streets and highways within their territorial limits and for an abuse of such authority, unwarrantably interfering with the performance of the railway's duty as a public service company, the company would have an appropriate remedy in the courts."

Extension of Safety Zone Idea in Louisville.—In addition to the safety zones which the traffic authorities have created at the downtown street intersections in Louisville, marked with the standards in some cases and indicated by the traffic policemen in others, broad white lines are being painted at intervals across the roadways so as to indicate to the pedestrians inside of which limits they can be assured of safety and to indicate to the motormen where the front ends of their cars are to stop. The experiment was tried first at Fourth and Green Streets, where several hundred persons gathered and watched the painting operation, the paint being applied directly on the wood-block paving. These lines cross the streets at right angles and are in line with the building fronts or inner line of the sidewalks. They do not last more than a day or so and have to be frequently renewed, but it is the impression that they will generally expedite pedestrian traffic and avoid congestion on the sidewalks at the intersections. That the regulation in the traffic ordinance providing for the stopping of automobiles outside the safety zone at downtown street corners when a street car has stopped to take on or let off passengers will be enforced is shown in the record of recent cases arising in the police court.

Personal Mention

Mr. W. T. Waters has been appointed advertising and publicity representative of the Georgia Railway & Power Company, Atlanta, Ga. Mr. Waters was born and educated in Atlanta, and for many years was on the staff of the Atlanta *Journal*.

Mr. Carroll H. Shaw has been appointed electrical engineer of the Sheboygan Railway & Electric Company, Sheboygan, Wis., to succeed Mr. W. B. Voth, superintendent of light and power. Mr. Shaw was born in Abington, Mass. In 1906 he entered the Massachusetts Institute of Technology, and was graduated from the electrical engineering course in 1910. Since that time he has been with the engineering department of the National Lamp Works of the General Electric Company at Cleveland, Ohio.

Major H. C. Evans, of the Lorain Steel Company, was a guest of honor at a dinner on Friday night at the Bellevue-Stratford, Philadelphia, to celebrate the thirtieth year of continuous affiliation with the company. The hosts were members of the sales department of the company and consisted of the following: Messrs. A. L. Verner, S. J. Cotworth, H. L. Gleeson, E. P. Thomas, W. B. Gresham, Daniel Coolidge, P. M. Boyd, Carroll Burton, E. B. Entwistle, A. S. Littlefield, S. P. McGough, William W. Kingston, J. A. Stacey and E. M. Noonan.

Mr. James C. Ernst has retired as the active head of the South Covington & Cincinnati Street Railway, Covington, Ky., as well as from the management of the Columbia Gas & Electric Company, the Union Gas & Electric Company and the Union Light, Heat & Power Company. In the future Mr. Ernst will be associated with these companies in an advisory capacity. Mr. Ernst has been connected with the South Covington & Cincinnati Street Railway and the Union Light, Heat & Power Company since 1896. He has been the active head of the Columbia Gas & Electric Company since its organization in 1907 and he has been associated with the Union Gas & Electric Company since 1911.

Mr. James Harmon, New Albany, Ind., for the last four years claim agent and safety agent for the United Gas & Electric Company and later of all the Insull properties in the New Albany-Jeffersonville-Louisville section, has been made general claim and safety agent for all of Indiana for the Insull properties. Mr. Harmon has risen from the ranks where as conductor he acquired a wide and practical familiarity with actual operating conditions. As claim and safety agent he had great influence in reducing the casualties on the Southern Indiana Insull lines. He was one of the first to use street-car cards to advertise correct methods of boarding and leaving cars and perfected for his company the periodical examinations of trainmen and other employees to keep them alert as to safety precautions. In his new post Mr. Harmon will have his headquarters in Indianapolis. He will be succeeded in New Albany by Henry Hutchins.

Mr. George B. Wheeler, secretary and general manager of the Chippewa Valley Railway, Light & Power Company, Eau Claire, Wis., and a past president of the Wisconsin Electrical Association, has resigned to devote his time to private interests. Mr. Wheeler's resignation followed twenty-three years of active management of the railway and light property at Eau Claire. Mr. Wheeler and his partners sold their interests in the Chippewa Valley Railway, Light & Power Company and the Chippewa River Water Power Company to the Kelsey-Brewer Syndicate, Grand Rapids, Mich., at which time all the old officers and directors retired. After engaging in journalistic work for a number of years, Mr. Wheeler entered the electric railway field in 1891 as general manager of the Eau Claire Street Railway, Light & Power Company. Subsequently he was appointed receiver of the property. When the company was reorganized Mr. Wheeler was elected secretary and general manager and the name was changed to Chippewa Valley Railway, Light & Power Company. Later the Chippewa River Water Power Company was organized for development work, and at the time of Mr. Wheeler's retirement this company owned all the water powers on the Menominee River and a valuable water power on the Chippewa River.

Construction News

Construction News Notes are classified under each heading alphabetically by States.

An asterisk (*) indicates a project not previously reported.

RECENT INCORPORATIONS

***Niagara River & Eastern Railroad, Niagara Falls, N. Y.**—Application for a charter has been made in New York by this company to build an interurban railway from the terminal of the Buffalo, Lockport & Rochester Railway in Buffalo along the right-of-way of the Niagara, Lockport & Ontario Power Company to Niagara Falls. Capital stock $1,500,000. Headquarters: Niagara Falls. Incorporators: E. G. Connette, president of the International Railway; Frank A. Dudley, vice-president of the Buffalo, Lockport & Rochester Railway; A. J. Porter and A. W. Gray, Niagara Falls.

Oil Belt Terminal Railway, Jennings, Okla.—Chartered in Oklahoma to build an electric railway from Coffeyville, Kan., through the oil fields of Oklahoma. Capital stock, $100,000. Incorporators: Joseph Hall, Cincinnati; W. A. Ledbetter, Oklahoma City, and W. N. Patterson, Muskogee. [E. R. J., June 13, '14.]

***West Virginia Electrical Company, Parkersburg, W. Va.**—Chartered in West Virginia to build an electric railway from Weston to Owensport, 50 miles. Connection will be made at Owensport with the lines of the Little Kanawha Railway.

FRANCHISES

Fresno, Cal.—The Fresno Traction Company has received a franchise from the Council on South J Street and Fresno Avenue in Fresno.

Long Beach, Cal.—The Pacific Electric Railway has asked the Council for a thirty-five-year franchise over certain streets in Long Beach.

Parker, Cal.—The Parker & Colorado River Electric Railway has received a franchise from the Department of the Interior to build an electric line through the Colorado River Indian Reservation. The proposed line will extend from Parker to a point near Ehrenberg, where a ferry will be constructed to receive freight for the Palo Verde Valley. Grading for this railway will be begun at once. W. H. Tharpe, is interested.

Sacramento, Cal.—The Pacific Gas & Electric Company has received from the Council an extension of time on its franchise in which to complete the extension of the Riverside line in Sacramento.

Marion, Ill.—The Southern Illinois Railway & Power Company has received a franchise from the Board of Supervisors of Williamson County to build an electric line from Marion to Carrier Mills.

Lafayette, Ind—The Lafayette & Northwestern Railway has received a franchise from the County Commissioners of Benton County to build an electric line from Lafayette to Kankakee where connection will be made with a line to Chicago. A branch line will be built to include Fowler, the county seat of Benton County. The terms of the franchise state that the line must be in operation from Lafayette to Rensselaer by Jan. 1, 1916. [E. R. J., Sept. 19, '14.]

***Alexandria, La.**—Messrs. S. A. Guy and W. A. Sullivan, Shreveport, have asked the Council for a franchise to build an electric line in Alexandria.

New Bedford, Mass.—The Union Street Railway has asked the Council for a franchise to extend and double-track several of its lines in New Bedford.

Westfield, Mass.—The Springfield Street Railway has received a franchise from the Council to build a double track on the south side of State highway, so that it will be possible to use the new underpass beneath the Boston & Albany Railroad tracks leading to the Westfield State Sanitarium and the East Mountain section in Westfield.

Worcester, Mass.—The Worcester Consolidated Street Railway has asked the Council for a franchise to relocate its tracks on West Street in Worcester.

Sharon, Ohio.—The Farrell Railway has asked the Council for a franchise to build an electric railway in Sharon.

Cornwall, Ont.—The ratepayers of Cornwall were to vote Oct. 14 on a by-law granting the Cornwall Street Railway, Light & Power Company a twenty-year extension of its franchise in Cornwall. Provision is also made for the rebuilding of the loop lines on Cumberland Street and Water Street in Cornwall.

Sarnia, Ont.—The Sarnia Street Railway has been authorized by the City Council to take up its tracks leading to the Pere Marquette Railroad station, and to relay them on Christina Street to Clifford Street and westerly on Clifford Street in Sarnia.

Richmond, Va.—The Virginia Railway & Power Company will ask the Council for a thirty-year franchise in Richmond.

Martinsburg, W. Va.—The Youngstown-Sharon Railway & Light Company has asked the Council for an extension of time on its franchise in Martinsburg.

TRACK AND ROADWAY

Hot Springs (Ark.) Street Railway.—Plans are being made by this company to begin work soon on the extension of the Malvern Avenue line in Hot Springs to the Hot Springs Country Club.

Pine Bluff (Ark.) Company.—Material has been ordered and work will soon be begun by this company on the extension of the East Sixth Avenue line in Pine Bluff.

Pacific Electric Railway, Los Angeles, Cal.—This company has taken initial steps toward connecting the Riverside line with the Los Angeles main line. The work of laying the track from the main line to the Riverside line will be begun at once.

California Terminal Railway, Sacramento, Cal.—This company, which plans to build an electric line from San Rafael to Sacramento, is obtaining right-of-way through Jamison Canyon in Solano County. C. W. Conlisk, San Francisco, is interested. [E. R. J., Oct. 12, '14.]

Sacramento (Cal.) Interurban Railway.—The project to build a 30-mile electric railway between Sacramento and Roseville, via Fair Oaks, Orangevale and small towns in Placer County, has been abandoned and the directors of the company have filed notice of dissolution with the Secretary of State. [E. R. J., April 6, '12.]

Pacific Gas & Electric Company, San Francisco, Cal.—The Chamber of Commerce is negotiating with this company for the possible raising of a bonus to extend the company's line to the Libby, McNeil & Libby plant in Sacramento.

San Francisco (Cal.) Municipal Railway.—Plans are under way for an extension on Columbus Avenue in San Francisco for a connection with the Union Street line to North Point Street, thence to Van Ness Avenue and thence to Chestnut Street to connect with the Van Ness Avenue line. Plans are also under way for an extension through the Fort Mason Military Reservation to Laguna Street at an entrance to the Panama-Pacific Exposition grounds; for the construction of the California Street line from Thirty-third Avenue to Second Avenue, thence along Geary Street to the Geary Street line; also for a line on Church Street.

Sausalito (Cal.) Incline Railway.—The Railroad Commission has granted this company a certificate of public convenience and necessity to operate an incline railway in Sausalito, Marin County. The company is also authorized to issue $15,000 of preferred stock or common stock for the acquisition of right-of-way and other property. Allen H. Vance, Sausalito, is interested. [E. R. J., June 6, '14.]

Waterbury & Milldale Tramway, Waterbury, Conn.—The Public Utilities Commission has granted this company authority to construct 2.88 miles of new track in Southington.

Washington Railway & Electric Company, Washington, D. C—This company is asked to consider plans to extend its line from Fourteenth Street and B Street southwest to the entrance of the new bureau of printing and engraving in Washington.

Jacksonville (Fla.) Traction Company.—Plans are being considered by this company to extend some of its lines in Jacksonville. An extension on Hogan Street from Bay Street to Eagle Street, Cedar Street and Pearl Street will soon be built.

Peoria (Ill.) Railway.—This company has placed in operation its new double track line on Main Street as far as Western Avenue in Peoria.

Terre Haute, Indianapolis & Eastern Company, Indianapolis, Ind.—Work will be begun at once by this company on the extension of the South Eighth Street line from H Street to M Street in Richmond.

***Keokuk, Ia.**—Plans are being made to build an electric railway from Keokuk, Ia., west to Wayland, Mo., thence south via Williamstown, La Belle, Newark, Bethel, Shelbyville, Shelbina, Paris, Mexico and Fulton to Jefferson City, about 140 miles. H. W. Knight, Chicago, represents a number of capitalists who are back of the project.

Orleans-Kenner Electric Railway, New Orleans, La.—Surveys have been completed by this company between New Orleans and Baton Rouge, 100 miles; grading has been completed from New Orleans to Kenner, 9 miles; grading is in progress from Kenner to St. Charles Parish, 2½ miles; 9.6 miles of track has been laid from both ends of this line and all contracts have been awarded to build this line to connect New Orleans, Hanson City, Harrihan, Harlem, Shrewsburg, Arnaults, Providence and Hanson City. The principal contractor is the Johnson & Company, Inc., 409 Tulare Newcomb Building, New Orleans. Officers: E. A. Stanford, New Orleans, president, and John Lorenz, secretary and treasurer. [E. R. J., July 18, '14.]

Bay State Street Railway, Boston, Mass.—Plans are being made by this company to relay the track on the south side of River Street in Haverhill this fall.

Holyoke (Mass.) Street Railway.—Work has been begun by this company installing a double track throughout Aldenville.

Transcona, Man.—By arrangement with the Transcona, Man., Council, J. H. Kern, who holds the franchise to build an electric railway in Transcona, to the boundary of the City of Winnipeg, is required to begin active construction on the line in the spring of 1915. It is said that certain preliminary work is being done, however, and that ties have been delivered along the route.

United Railways, St. Louis, Mo.—Plans are being considered by this company to have its Union Avenue line extended to the city limits of St. Louis.

Trenton & Mercer County Traction Corporation, Trenton, N. J.—This company is asked to consider plans to extend its lines from Crosswick to Allentown and Hightstown.

Piedmont & Northern Railway, Charlotte, N. C.—An extension between Spartanburg and Gastonia, 32 miles is being planned by this company. An extension northward from Charlotte to Concord, N. C., about 25 miles is being considered and another extension from Concord to Salisbury, Greensboro and Durham is also being contemplated. The work on the Concord branch will be begun first.

Columbus Railway, Power & Light Company, Columbus, Ohio.—An extension of the Arlington line in Columbus into the new addition as far as the intersection of Arlington Avenue and Cambridge Boulevard is being planned by this company.

Ardmore & Western Interurban Railway, Ardmore, Okla.—As soon as financial backing can be obtained work will be begun by this company on its line between Ardmore and Oil City. [E. R. J., May 30, '14.]

Cushing (Okla.) Traction Company.—Preliminary arrangements are being made by this company to build its 13-mile line from Cushing to the oil fields. R. D. Long, McAlester, is interested. [E. R. J., Jan. 6, '14.]

Oil Belt Traction Company, Oklahoma City, Okla.—Since the announcement that this company plans to build an electric line from Coffeyville, Kan., through the northern oil fields numerous towns and cities are trying to be included in the system. The present plans are to extend the line south via Bartlesville, Miami, Afton, Tulsa and Chandler to Oklahoma City, together with intermediate points. Centralia, an inland town near Afton, has offered the company 10 miles of right-of-way, 5 acres of land for depot purposes and $5,000 as a bonus. [E. R. J., June 13, '14.]

London & Port Stanley Railway, London, Ont.—The electrification of this railway, the city's road to Lake Erie, will not be delayed on account of the war, and rehabilitation work is being rushed ahead.

London & Port Stanley Railway, London, Ont.—The rehabilitation electrification of this railway, the city's road to Lake Erie, will not be delayed on account of the war.

***Mexia, Tex.**—Plans are being considered by the Mexia Commercial Club to obtain a franchise to build an electric railway in Mexia.

Kelso & Eastern Railroad, Kelso, Wash.—No definite plans have yet been decided upon by this company in connection with the construction of the proposed line between Kelso and Mayfield. J. L. Harris, Kelso, president. [E. R. J., Oct. 4, '14.]

Mercer Electric Railway, Athens, W. Va.—Grading has been completed and as soon as financial backing can be obtained work will be begun by this company on the construction of its 7-mile line between Athens and Princeton. R. G. Meador, Athens, president. [E. R. J., July 29, '14.]

Weston & Glenville Electric Railroad, Weston, W. Va.—The proposed plan to build a 25-mile electric railway between Weston and Glenville is still in the preliminary stage. Lloyd Rinehart, Weston, is interested. [E. R. J., Dec. 27, '14.]

Janesville & Madison Traction Company, Madison, Wis.—Surveys have been completed by this company for its 43-mile line between Janesville and Madison, via Edgerton, Albion, Stoughton, Skirting Lakes and Lake Morona. C. A. Van Ness, Madison, secretary. [E. R. J., July 25, '14.]

SHOPS AND BUILDINGS

Northern Electric Railway, Chico, Cal.—Work will be begun at once by this company on the new depot at the corner of Myers Street and Robinson Street in Oroville.

Iowa Railway & Light Company, Cedar Rapids, Ia.—Plans are being made by this company to enlarge its passenger station at Cedar Rapids.

Mesaba Electric Railway, Virginia, Minn.—This company has completed its new carhouses between Virginia and Mountain Iron. They are equipped with machinery for repairing cars and motors.

Southern Traction Company, Dallas, Tex.—New passenger stations will be erected at once by this company in Abbott, Corsicana, Forreston and Milford. The structures will all be one story and of brick construction. Each depot is estimated to cost $3,000.

POWER HOUSES AND SUBSTATIONS

Shore Line Electric Railway, Saybrooke, Conn.—This company is installing the following new equipment at its power house at Thamesville: one 1875-kva Westinghouse-Parsons turbo-alternator, 25 cycles, 2300 volts, 3625-kva step-up transformers 2300 to 2200 volts; a 25-kw, 125-volt, motor-driven exciter, a new high-tension switchboard, a 500-hp Edgemoor boiler equipped with a Westinghouse underfeed forced draft stoker and a 6 x 12 x 10 outside packed Worthington boiler feed pump.

Columbus Railway, Power & Light Company, Columbus, Ohio.—It has been announced that this company will at once install in its Gay Street power house a new 1000-kw motor generator set, an order for which was placed some time ago.

Bryan & Central Texas Interurban Railway, Bryan, Tex.—Work has been begun by this company on the concrete foundations for its new power plant in Bryan. The generators, engine and all necessary equipment has been ordered.

Glen Rose & Walnut Springs Railway, Walnut Springs, Tex.—Plans are being contemplated by this company to build a new power plant between Glen Rose and Walnut Springs.

Monongahela Valley Traction Company, Fairmont, W. Va.—Plans are being made by this company to build a new power plant in Hutchinson.

Manufactures and Supplies

ROLLING STOCK

Kansas City (Mo.) Railway is reported to have sent out specifications for forty new cars.

Ogdensburg (N. Y.) Street Railway has ordered one carbody from the Wason Manufacturing Company.

Dallas (Tex.) Consolidated Street Railway has received twenty cars built by the American Car Company.

Kansas City, Clay County & St. Joseph Railway, Kansas City, Mo., has ordered one line car from the McGuire-Cummings Manufacturing Company.

Geary Street Municipal Railway, San Francisco, Cal., has ordered fifty more cars from the Jewett Car Company, now making a total of 175 cars ordered.

Danville (Va.) Traction & Power Company, Danville, Va., has ordered two cars from the Southern Car Company. The Westinghouse Electric & Manufacturing Company will furnish the electrical equipment, consisting of quadruple 40-hp motors and control.

Boston (Mass.) Elevated Railway has ordered six center-section car bodies for articulated car bodies from the Laconia Car Company, in addition to the previous order for thirty-seven center-sections noted in the ELECTRIC RAILWAY JOURNAL of Sept. 12, 1914. The company is also planning to send out next week specifications for a large number of trail cars, for use in its new Boylston Street subway.

Cleveland (Ohio) Railway, noted in the ELECTRIC RAILWAY JOURNAL of Aug. 8, 1914, as having ordered 100 prepayment center-entrance motor cars from the G. C. Kuhlman Car Company, has specified the following details for this equipment:

Seating capacity	62
Weight, exclusive of trucks and motors	21,052 lb.
Bolster centers, length	26 ft.
Length over vestibule	50 ft.
Width over sills	8 ft. 2 in.
Width over all	8 ft. 4½ in.
Height, rail to sills	25½ in.
Height, sill to trolley base,	9 ft. 6 1/16 in.
Body	semi-steel
Interior trim	cherry
Headlining	Agasote
Roof	plain arched
Underframe	metal
Air brakes	West.
Axles	Pollock
Bumpers	ry. std. 6 in. chan.
Cables	ry. std.
Car trimmings	ry. & Kuhlm.
Control	West.
Couplers	O-B.
Curt'n fixtures	Cur. Sup. Co.
Curtain material	Pantasote
Destination signs,	Hunter Illuminated
Door signal device,	Elec. Serv. Sup. Co.
Fare boxes	Cleveland
Fenders	Eclipse
Gears and pinions	West.
Gongs	Brill
Hand brakes	ry. co.'s vert.
Heaters	Peter Smith
Headlights	Dayton
Journal boxes	Symington
Motors,	4 West. 340, outside hung
Paint	Sherwin-Williams
Sanders	Nichols-Lintern
Sash fixtures	Kuhlman
Seats,	Brill trans. and long. rattan
Trolley base	ry. std.
Trucks	Brill 51-E-1
Varnish,	Outside, Chicago Varnish Co.; inside, Wright Bros.
Ventilators	Scullin's design
Wheels,	Pittsburgh Forged Steel Co.

TRADE NOTES

W. T. Kyle has joined the sales force of the Okonite Company at its general office, 253 Broadway, New York. Mr. Kyle for the past six years has been connected with the Duplex Metals Company as district sales manager.

Union Switch & Signal Company, Swissvale, Pa., has received an order from the Chicago, South Bend & Northern Indiana Railway to install a.c. automatic block signals between its car barns and Weller Avenue, La Port, Elkhart and Miller, Lake Erie crossing, La Port and Winklers, South Bend, and on the Southern Michigan, South Bend and State Line. There will be sixty-four one-arm, Style "B," upper quadrant, left-hand semaphore signals operating in two positions between 0 deg. and 45 deg. They will be installed on the TDB system, which permits two trains to be between turnouts going in the same direction, but prevents opposing movements. The signals will be controlled by continuous a.c. track circuits and the materials and construction will be similar to the installation already in service which was recently installed by this signal manufacturer.

Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., has received an order from the Waterloo, Cedar Falls & Northern Railway, Waterloo, Ia., for 600/1200 volt railway apparatus for operation over its new 60-mile extension between Waterloo and Cedar Rapids, consisting of the following equipment: Five 60-ton locomotive equipments, seven high-speed equipments for two-car train operation in limited parlor-buffet and observation service, five equipments for local passenger and baggage service, four trailer equipments for local train service, one express car equipment, and one line car equipment. This company has also received the following orders for equipment: Cleveland (Ohio) Railway, 408 type No. 340 motors and control for quadruple equipments for low-floor center-entrance cars; Washington-Virginia Railway, five quadruple motor and pneumatically operated control equipments; Kansas City, Clay County & St. Joseph Railway, one combination freight and work car equipment, consisting of quadruple No. 327-C motors and double end electro-pneumatically operated unit switch control, for 600/1200 trolley operation; Ogdensburg (N. Y.) Street Railway, one double equipment of No. 323-A motors and control; Seattle (Wash.) Municipal Street Railway, one quadruple equipment of No. 310-C motors and double end unit switch control of the electro-pneumatic type, with an additional feature of an emergency brake operated by means of dynamic braking.

ADVERTISING LITERATURE

Tool Steel Gear & Pinion Company, Cincinnati, Ohio, has issued a folder which contains comparative data on the wearing qualities of case-hardened and tool steel gears and pinions.

Union Switch & Signal Company, Swissville, Pa., has issued Bulletin No. 79 which describes its electric crossing gate, and Bulletin No. 80 describing its model No. 13 low voltage, d.c. switch movement.

Goldschmidt Thermit Company, New York, N. Y., prints in its quarterly publication, *Reactions*, an illustrated article on welding rails with thermit and grinding joints on the San Antonio (Tex.) Street Railway.

American Rolling Mill Company, Middletown, Ohio, has issued a catalog which contains a large number of testimonial letters in regard to its products, among which are included condensers, boiler tubes, culverts and sheet-metal work for buildings.

Root Spring Scraper Company, Kalamazoo, Mich., has issued a thirty-two-page illustrated pamphlet entitled "The Passing of the Sweeper." In this the Root spring scraper is described and mention is made of its efficiency in handling snow. This company's railway spring scraper, special Root scraper, manually or air operated, the Kalamazoo scraper and the Root spring life guard are illustrated and described in detail.

W. N. Matthews & Brother, Inc., St. Louis, Mo, have issued a sheet which illustrates in detail their holdfast lamp guards. A clamping collar locks the guard to its socket. The guard does not touch the lamp anywhere and holds the lamp so that it is always at least 1 in. from any combustible material. A special spring cushion absorbs shock and vibration.

Bayonet Trolley Harp Company, Springfield, Ohio, has issued a folder which discusses the defects and remedies for trolley equipment. In this little treatise quotations are liberally taken from the articles of C. W. Squier, assistant engineer New York Municipal Railway Corporation, which have appeared from time to time in the ELECTRIC RAILWAY JOURNAL. The valuable suggestions of Mr. Squier on trolley maintenance, expressing as they do the results of practical experience and careful observation, are supplemented in the folder by comments showing how the trolley equipment manufactured by this company meets the requirements outlined in his articles.

Electric Railway Journal

Published by the McGraw Publishing Company, Inc.
Consolidation of Street Railway Journal and Electric Railway Review

Vol. XLIV NEW YORK, SATURDAY, OCTOBER 24, 1914 No. 17

THE BASIS OF OPTIMISM

In an interesting interview, published elsewhere in this issue, H. Hobart Porter points out the relation between the industrial situation and the gross earnings of electric railway companies. These have not shown as great decreases in business caused by the war as the steam railroads, and this comparative stability of earning power, as Mr. Hoyt, of N. W. Halsey & Company, pointed out in our issue of Oct. 10, constitutes one great merit of electric railway securities in the eyes of bankers. The general economic situation, however, is improving. Already the West is beginning to feel the benefit of the export sales of grain, negotiations are reported from Washington looking toward the marketing of a large part of the cotton crop, and large foreign government orders are stimulating individual industries throughout the country, particularly among the textiles and some branches of the machinery trade. The electric railway companies should soon begin to feel this revival of business. Their normal annual growth of traffic, excluding that from any extensions, is about 5 per cent, and if there has been a setback in this increase during the last few months it ought to be added to the normal growth with the general revival of business. This country is not in a critical financial condition. It is producing in abundance the primary necessities of life, and general business should rapidly approach its normal footing with the clearing up of the banking situation, which should not long be delayed.

THE SOPHISM OF LOCAL CONDITIONS

In discussions at gatherings of street railway operators, where practices are compared either informally or on the floor of the convention, one constantly hears the phrase "local conditions." This expression is used to justify or explain some practice in vogue that is divergent from generally accepted standards. It applies particularly to transportation questions although unusual designs of car bodies apparently are often explained by the same phrase. Frequently it will be found on investigation of the factors involved that there is no fundamental condition or compelling reason for divergence from generally accepted practice, and it is difficult to avoid the conclusion that a lack of discriminating analysis and a near approach to provincialism is indicated when an operating man allows himself to drift into the state of mind where such a vague generality is submitted as logic. When the phrase "local conditions" is advanced as a reason or an explanation, the person to whom it is addressed should not accept it as adequate without himself weighing all the influencing factors and drawing his own conclusions as to its adequacy. As an excuse for moribund practices or for the magnification of petty detail it has been done to death.

TROLLEY FREIGHT TO PUBLIC MARKETS

At this time a strong effort is being made by the New York City administration to establish a large number of public markets in order to lower the cost of living. One suggestion which is being considered with favor is that the electric railway be utilized to bring farm produce to the city. Electric freight would be a novelty to New York, although the Brooklyn Rapid Transit System once had a fleet of refuse cars under municipal contract and also a number of express cars for one of the old-line companies. The Brooklyn company now conducts a large electric freight business, but this is chiefly in connection with dock shipments and not with outlying truck farms. Public sentiment in New York hitherto has not favored the extended operation of trolley freight on the grounds of unsightliness and noise. It is difficult to see, however, the propriety of this criticism. If the freight was not taken through the streets by car it would have to be carted over the same streets in a larger number of much noisier trucks, and the cars make no use of the street pavement which the trucks wear out rapidly at the expense of the taxpayers. Finally, such a car service need not interfere with the busiest city schedule since produce cars going inward would naturally be operated only during the very early morning hours, while they could be returned during any of the slack hours of the day. The present is therefore a favorable moment for the electric railways in and about New York to follow the example set for years by the Western interurbans in inaugurating and building up a service that will earn good profits and the gratitude of the ultimate consumer.

DISCIPLINE OF RAILWAY RECRUITS

An easy-chair reading of the recent convention discussions at Atlantic City will bring to light many valuable ideas for the electric railway operator, but none of greater worth than that of recruit discipline as practiced on the Syracuse properties of the New York State Railways. It has been so long the custom to place all platform men on the same basis of discipline regardless of their experience that any move toward a preferential system may seem revolutionary. It is revolutionary openly to acknowledge and practice such segregation, yet he would be a poor superintendent indeed who did not discipline a new man with less rigor than a hardened offender. However, the policy described by Mr. Duffy is commendable in treating the matter of discipline according to sound pedagogical principles. In Syracuse it is not the superintendent who is the disciplinarian for the hundred and one minor infractions which the novice commits during his first six months, but the instructor, the same man who had lately released the student as fit to operate a car. This plan is one that "blesses him that gives and him that takes." The superintendent gives up a part of his prerogatives, but in exchange therefor he is relieved of the disagreeable task of teaching a man what he ought to know when he leaves the care of the instructor. The instructor, on the other hand, can do better work because he knows where his teaching has failed in practice. Another advantage is that the instructor remembers the degree of aptitude and willingness shown at school by the novice, whereas every green motorman or conductor is practically a stranger to the superintendent. Thus the Syracuse system is a frank acknowledgment that the instruction of a platform man matures in the responsible handling of his car and not in the classroom.

DRAINAGE AND TRACK FOUNDATIONS

The report on proper foundations for track in paved streets, as submitted by this year's way committee, is one of the most valuable contributions with which the industry has been favored in recent years. Anyone who has had occasion to compare the different types of track foundation used in this country will readily realize the great variation in foundation design installed to perform practically the same service under the same conditions. All of these cannot be the best, and the committee's study should help greatly to bring about standardization, or at least greater uniformity, in this important branch of electric railway engineering. While it appears unfortunate that the rules of the standards committee did not permit the Engineering Association to accept the four recommended track designs other than as "information," the present enormous diversity in foundation conditions probably made any other course impracticable.

We have no doubt that some track engineers, conscious of their own peculiarities of soils, grades, rainfall and other conditions, may take exception to certain individual features in the proposed sections. Perhaps the greatest degree of dissent will arise in connection with the underdrains suggested for types *C* and *D* concrete foundations. Undoubtedly in these types the bearing power of the subsoil is not so likely to be affected by water because the ties are completely surrounded with concrete and the subgrade would also be filled with practically waterproof material. But in type *C* construction, certainly, we believe that seepage from the pavement surface should definitely be cared for. This can be done by providing weepholes with outlets to a sewer system so that they will not drain into the subgrade. Otherwise water from higher ground near by might back up to the subgrade and cause the tracks to heave in freezing weather. Doubtless one reason why the committee showed underdrains for concrete constructions was to provide for those cases where the heavy absorption of water by the soil would leave the subgrade resting on a precarious foundation.

As to the types *A* and *B*, or the ballasted constructions, we believe that it would be practically impossible to eliminate water from them unless underdrains such as the committee suggests are provided. If this was not done, the entrance of seepage water would carry silt into the voids of the ballast from the sides and bottom of the subgrade, and this silt, in time, would reduce the bearing power of the ballast.

These, however, are matters of detail upon which there may be a legitimate difference of opinion. The committee may rest content in the knowledge that it has given the fraternity a set of designs which represent a big step toward the ideal track.

MODERN CAR LIGHTING

The discussion on car lighting which was held at the Oct. 14 session of the Engineering Association, revealed clearly that the days of the bare filament lamp are numbered. So long as only the comparatively inefficient carbon lamp was available for car lighting the number and candle-power of the units necessarily was limited for economic reasons. The initial effect of the introduction of the more economical tungsten lamp was simply the substitution of tungsten for carbon bulbs in the same sockets except that the new units were of greater capacity. It soon became evident, however, that more light was by no means synonymous with better light, because the bare filament tungsten lamp proved too dazzling to the human eye. In fact, where the car finish was a pure white, the very reflection of the lamps proved fatiguing. After the general use of the tungsten filament had made the question of energy consumption of relatively less importance a number of companies began to experiment with the use of reflectors to see whether car lighting could not be made as agreeable as the illumination of rooms in a stationary structure.

These pioneer attempts, begun little more than two years ago, soon brought out the fact that the manufacturers would have to develop lighting fixtures suitable for at least two conditions incident to car operation, namely, breakage from vibration and security against robbery. Apparently these conditions have now been met to a degree which is great enough to justify serious consideration of reflector lighting by electric railways generally. There is still a division of opinion with regard to the number and capacity of units, some favoring say sixteen 23-watt lamps and others preferring one circuit of 94-watt units. Both parties are agreed, however, that reflector lighting makes a light interior car finish more instead of less agreeable to the eye and that it produces appreciable economies in the initial lamp capacity. As one of the speakers intimated at the discussion, it is now incumbent upon the electric railway to abolish the bare filament lamp before any serious agitation on the subject is stirred up by civic betterment organizations.

ZONE FARES IN MILWAUKEE

City systems which are face to face with the problem of the increasing cost of transportation and the diminution of the 5-cent fare will find a possible solution in the paper by Mr. Stearns elsewhere in this issue. This paper was presented at Atlantic City last week, but on account of the time necessary to reproduce the illustrations its publication was postponed until to-day. The problem initially in Milwaukee did not differ from that in most American municipalities. It is one which is bound to arise as the result of the growth of every city, the consolidation of its surface railways and the extension of the 5-cent fare to all points within the city limits. This is a common condition, and in cases of this kind there are certain to be apparent discriminations in fare within the single-fare district. These discriminations can easily be found, as Mr. Stearns says, by the use of a ruler and a map, and they necessarily result in complaints and demands for lower fares from those outside the 5-cent limit who think they ought not to be obliged to pay two fares when other sections are receiving as long or a longer ride for a single fare. Such demands sound plausible when considered by those who do not realize that the system of fares in use is a somewhat chaotic development and inheritance from previous days. At the same time, when these demands are backed by real estate promoters who care nothing about the financial welfare of the railway company but only want the lower fares to help them sell lots, they constitute a serious menace not only to the railway company but to the character of service which that company can give to other sections of the city.

This, in brief, was the problem presented to The Milwaukee Electric Railway & Light Company and the Wisconsin Railroad Commission, and the answer in that case was the zone system described by Mr. Stearns. This system retains for the metropolitan district the basic 5-cent fare but provides for additional fares of 2 cents for zones or belts outside of the central district. The latter does not correspond with the corporate limits of Milwaukee but is an area of 8 to 9 miles in length and 6 miles in width. The introduction of this system necessarily increased some fares, even within the city limits, but not, of course, to the extent of another nickel, and on the whole it has given entire satisfaction to the public. This fact is evidence of the contention sometimes made that long distance riders on a city system will not seriously object to a fare corresponding to the length of their ride, provided other parts of the city are not on a very different basis. In its practical application the zone system necessarily involves complications in fare collection, but these seem to have been carefully worked out in Milwaukee and to be simple of application by both the public and employees of the railway.

The financial statements presented by Mr. Stearns show that even with this increase in fare the suburban lines at Milwaukee as a whole are not profitable. This also is undoubtedly a general condition. But if a city system is fairly profitable and the community is growing, a railway company can carry a number of slightly unremunerative suburban extensions in the hope that they will develop later into profitable feeders.

We are glad to see such an interesting departure from standard American practice in fare collection set forth with so much detail as in Mr. Stearns' paper. It holds forth a great deal of promise for many American localities. A large number of states now have commissions with powers over rates as great as those possessed by the Wisconsin commission, and there would seem to be no legal objection in most instances for an application of this remedial measure elsewhere.

BIG WHEELS NEEDLESS ON TRAILERS

The prominent display of dwarf-type railway motors at the last convention of the American Electric Railway Association was a strong demonstration of the faith which the manufacturers now have in the permanence of a design that but lately was classed as a freak. It is evident also that the progressive electric railway operator is prepared to encourage the efforts of the manufacturers, if we are to judge by the adoption of this new motor by such roads as the Mahoning & Shenango Valley Railway, the Third Avenue Railway, New York, and the United Railroads of San Francisco. The last-named company went to the trouble of making extended tests, as detailed in our issue of Aug. 8, and secured very favorable results in the saving of energy by substituting dwarf motors with 24-in. wheels for old motors with 30-in. diameter wheels. At the same time, of course, a substantial reduction in step height was attained.

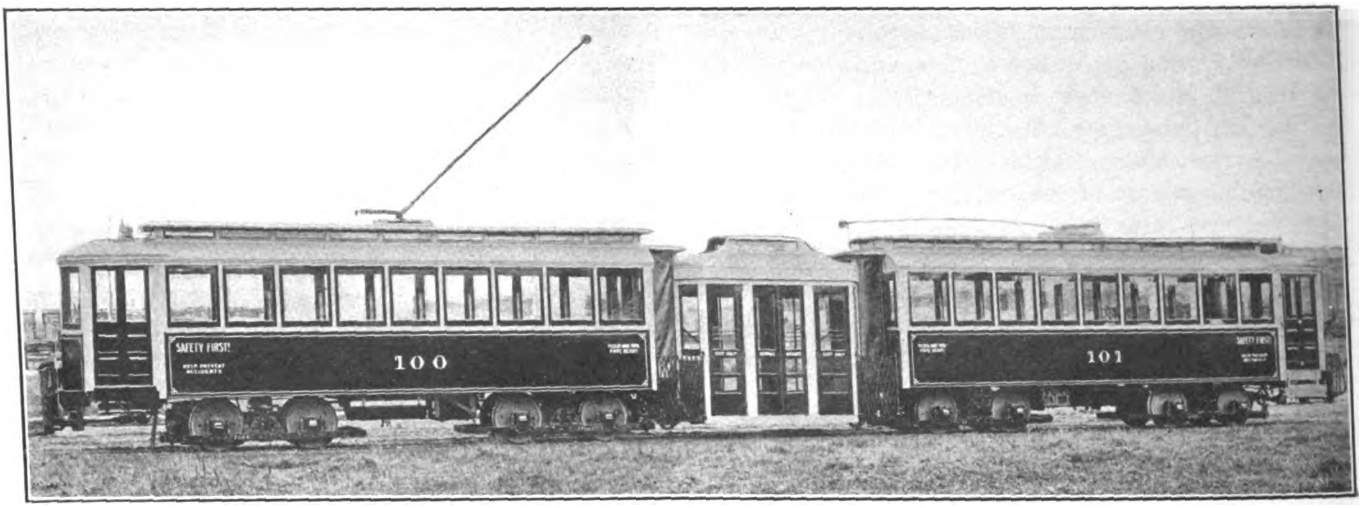
These cases are mentioned to show that other companies are finding the Pittsburgh low-wheel idea perfectly feasible for their motor cars, yet some very recent orders for cars otherwise modern show that the adaptability of the small-wheel principle even for trailer service is not widely appreciated. So far as motor cars are concerned, it is to some extent understandable why the ultra-conservative operator should stick to the big wheel and big motor. Perhaps he does not think it worth while to depart from present standards for the sake of a small fraction of new cars; or he may feel that the maintenance reliability of the dwarf motor over, say, five years is still an uncertainty. But such reasoning does not apply to the operator who is beginning the use of trailers. His very success in trailer operation will depend upon using a light and inexpensive car that permits rapid and easy exit and entrance. Therefore, he must not consider his trailer primarily as a car which could go into motor service but rather as a special design for a special purpose. To use big wheels, and consequently a high step, in a car which has no motors is to misunderstand the trailer situation completely. The location of draft rigging on the cars of the train offers practically the only mechanical problem and this is a small one indeed, compared with the juggling that has been required to lower motor car steps 3 in. or 4 in. Where so much ingenuity has been applied to the steps of the motor car, it is not unreasonable to expect the trailer to be a low-floor car as a matter of course.

Twin Cars in Portland, Ore.

Several Cars of the Articulated Type Have Been Placed in Service in This City—They Are Built from Old Double-Truck Cars of Small Size and Provide Units Seating Sixty-Four Passengers

The Portland Railway, Light & Power Company, Portland, Ore., which is managed and operated by E. W. Clark & Company, Philadelphia, is having much success in the operation of its new "twin cars." These cars, rebuilt from the old high-step trolleys, follow, in a general way, the articulated type of car used in Boston, with this principal exception: the Portland cars utilize two double-truck car bodies, whereas those in Boston use only single-truck cars. Complete separation of incoming and outgoing passengers is effected and a double interlocking system of signals between conductor and motorman has been introduced.

The objects sought in the reconstruction of the smaller units into "twin cars" may be summarized as follows: to utilize effectively and profitably the heavy investment in small cars of low carrying capacity; to obtain a unit which will hold a large number of passengers, thus reducing the number of cars operated during the rush periods; to reduce platform cost where two-car trains are now operated; to extend the prepayment feature to cars not so designated, and to reduce accident risk.



TWIN CARS IN PORTLAND—GENERAL VIEW OF CAR READY FOR SERVICE

STRUCTURAL DETAILS

The "twin car" consists of three compartments, of which the two end sections are 34-ft. 6½-in. cars with one vestibule and platform removed from each, and the middle section is the suspended platform for the two cars. This middle section acts as a flexible connection between these two cars and is used only for entrance, exit and fare collection. The conductor is stationed in this middle compartment, hence the advantages of the center entrance prepayment type of cars are obtained. No trucks are under the center compartment, and therefore but one step from the street into the car is required.

The length over bumpers is 73 ft. 4 in., the middle section being 12 ft. center to center. The equipment consists of four GE-58 motors, with K-6 controllers and GE emergency air-brake equipment. The floors of the two end cars are 36 in. above the rail, and this distance is divided into three steps, the first, of 14 in., being from the street to the main floor of the center compartment, the second, of 12 in., to a platform on either end of this middle section, and the third, of 10 in., comprising a portion of the pivotal connection between the compartment and the car body. The last step is circular and built on the center sills of the original platform. When the car takes a curve this step rotates over a circular toe-board rising from the 12-in. platform of the middle section. Sufficient clearance is provided between this toe-board and the circular step, and free rotation is afforded, thus forming a perfectly safe and comfortable passage even on the sharpest curves.

The center compartment is carried on a steel underframe pivoted on center bearings, supported both by the lateral sills extending from the car body and by a center pin pendant from a bearing rigidly fastened to the original platform sills. Roller bearings on the steel underframe are set on radial side bearings under the circular step.

Double curtains on spring rollers inclose the passageway between the middle and end sections. The inner curtain, of pantasote with cloth lining exposed, clears the floor by several inches and reaches only shoulder high. This curtain can easily be removed for cleaning. The outer curtain of 12-oz. waterproof canvas extends from below the circular step level to the ceiling.

The roof section of the pivotal connection is hinged to the transom of the center compartment and bears on the transom roof of the end section. This permits carrying the roof line of the car bodies through the middle section and thus suggests the appearance of a center entrance car. This effect is increased by life guards pendant from the ends of the car bodies and dropping from the side sill level to the level of the bottom sill of the center portion. Pantograph gates are supported in brackets between the compartments.

The steel underframe consists of a set of four 5-in. channel irons extending the full length of the center section. The ends of these beams are supported by the upper center bearings, and their middle portion is shaped by reverse curves at either end so as to drop below the floor level. The side sills are 4-in. x 4-in. angle-irons, spaced the width of the center section apart. Their ends are bent inward and upward to connections on the channel irons and form the end sills of the middle section. The side sills are 1 in. below the level of the center sills and form a convex ramp laterally through the center compartment. Diagonal braces, from corner to corner, and lateral end braces with side end truss members complete the underframe.

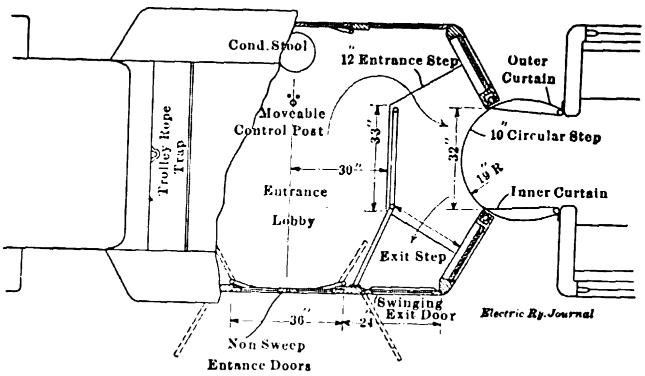
ENTRANCE AND EXIT FACILITIES

A pair of center entrance doors are adjoined by exit doors on either side. The entrance doors are of the "non-sweep" type and are hinged in the center on a pivot, the movement being controlled by a roller on the outer edge which runs in a slotted guide-way above the doors. The exit doors are of the simple swing type with check. The conductor's station is opposite the entrance doors behind a movable post. A permanent barrier at the end of each the platform steps and movable barriers between the entrance and exit doors separate the streams of entering and leaving passengers. The entering passengers cross the center section and pass the conductor on either side before reaching the platform step.

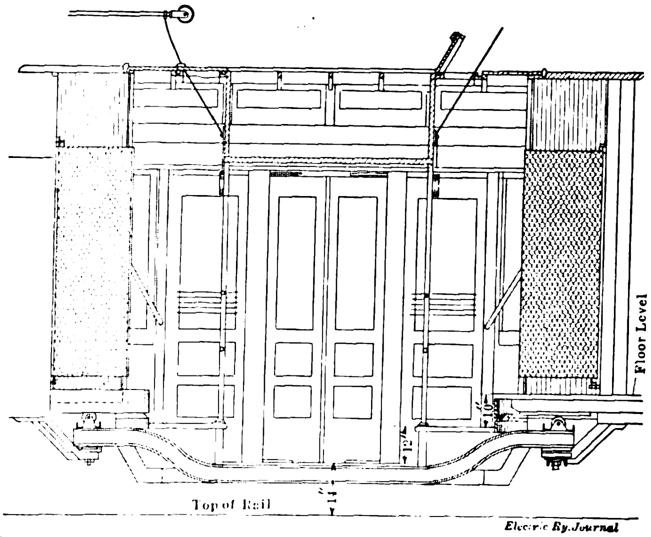
The fare-registering and door-operating devices are mounted on the above mentioned movable post, as are also the conductor's stool and bell cord signal to the motorman. This post is shifted to the opposite side of the compartment when the direction of the train is reversed. All connections are automatically made when the post is placed in position. This is accomplished by a set of plugs entering sockets in the floor and overhead rods. Three hand levers and a pedal mounted on this post control the entrance doors, the exit door, the register shift and the register respectively. Overhead rods connect the doors and register with the post. The entrance doors are opened and closed by the conductor. The exit door is unlocked and locked by the conductor, but must be pushed open by the leaving passengers. A small electric light in each motorman's cab is connected in a circuit which is only completed when the entrance and exit doors are closed and locked. As a double precaution against boarding and alighting accidents, the bell cord signals, by a ball and tube mechanism attached to the door operating devices, are locked to prevent possible signaling unless the doors are closed and locked.

The trolley poles are carried through a slot in the ventilators on either end of the center section. Trolley catchers are used. An emergency valve, which can easily be operated by the conductor, enables the latter to apply the air brakes independent of the motorman in case of emergency.

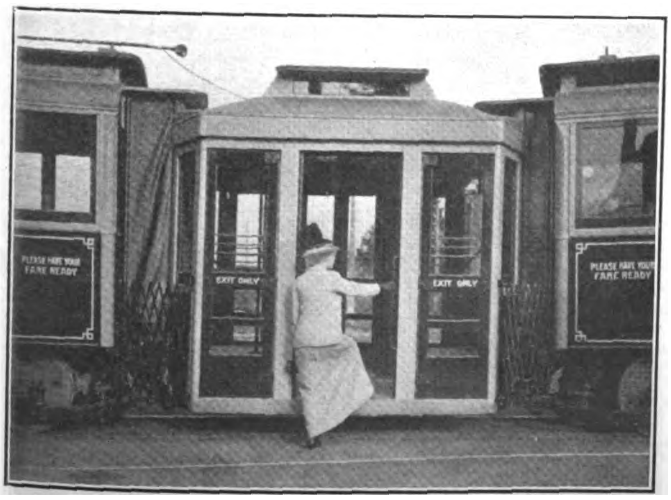
The motorman has exclusive use of the end platform and door. A movable seat on the rear end locks the door and, with its opposite stationary seat, increases the original seating capacity of the train by four passengers; thus making the total seating capacity of the "twin car" sixty-four. There are at present four of these cars in operation.



TWIN CARS IN PORTLAND—PLAN OF VESTIBULE SHOWING ARRANGEMENT OF EQUIPMENT



TWIN CARS IN PORTLAND—ELEVATION OF ENTRANCE AND EXIT VESTIBULE



TWIN CARS IN PORTLAND—VIEW SHOWING EASY ENTRANCE FACILITIES

The cost of constructing the first of the "twin cars" to be built was approximately $1900, but it is expected that the cost in the future will be but $1000, the difference in figures being caused by high cost of preliminary design, patterns and changes due to experimental work.

For subsequent cars which are now under construction in the company's shops a number of changes are to be made in order to improve the external appearance, but the general construction of the new cars will be identical with those first built. The principal change will be the carrying of the roof line of the two car bodies through the middle section, this being planned for the sake of appearance.

The engineering experiment station of the University of Illinois has issued a bulletin entitled "The Thermal Properties of Steam," No. 75 in the series. It was prepared by C. A. Goodenough and presents a critical discussion of the experimental investigation of the various thermal properties of steam, an outline of the thermodynamic relations that must be satisfied, and the development of a general theory of superheated and saturated steam. It is believed that this formulation of the properties of steam give absolute thermodynamic consistence, extreme accuracy, simplicity, flexibility and great range of validity. Copies of the bulletin may be obtained without charge from C. R. Richards, acting director of the experiment station, Urbana, Ill.

A Zone System of Fares in Practice[*]

This Is a Comprehensive Description of the First Extended Application in This County of the Zone System of Fares for City Lines—Full Detail of Earnings and Expenses Are Given—Data from European Cities Are Appended

BY R. B. STEARNS, VICE-PRESIDENT AND ASSISTANT GENERAL MANAGER THE MILWAUKEE ELECTRIC RAILWAY & LIGHT COMPANY

A zone system of street railway fares and collections applicable to suburban and interurban territory in place of the nickel system almost universally used in American cities and suburbs has been placed in operation during the last year on the urban, suburban and interurban lines of the Milwaukee company. The system to be described is a practical attempt at the fixing of street railway fares so that they will vary more or less closely with the distance traveled and in some respects is not unlike the zone system on the electric railways of England and the Continent. The treatment in the central district, however, is substantially different and is necessarily so in order to accord with American conditions. While fares so fixed are not exactly in line or parallel with the cost of service, they are quite likely to prove more so than flat fares for longer zones. It is believed that this is the first attempt on a relatively large scale to introduce small increments of distance traveled for small increments in the way of added fare.

While the system may at first appear complicated in operation, in point of fact it is relatively simple, and predicted difficulties of fare collection have not developed. The general scheme was referred to in President Harries' address at the 1913 convention.

THE MILWAUKEE RAILWAY SYSTEM

The Milwaukee railway system comprises 417 miles of surface tracks, of which 175 miles are located in the city of Milwaukee, 60 miles serve the suburbs of Milwaukee, 20.5 miles comprise the local system in the city of Racine, and the remaining 161.5 miles are essentially interurban. The interurban tracks extend southward 37 miles to Kenosha, passing through several municipalities, including Racine, which has a population of 40,000. They also extend 51 miles to the west, passing through the cities of Waukesha, Oconomowoc and Watertown, and 37 miles to the southwest, passing through Hales Corners, St. Martins and East Troy, with a branch line from St. Martins through Waterford and Rochester to Burlington. On the entire system there are operated 686 passenger cars, carrying about 150,000,000 passengers per annum.

FORMER RATES OF FARE AND DISTANCES

The fare charged within one fare limit of Milwaukee is 5 cents cash, six tickets for 25 cents, twelve tickets for 50 cents, and twenty-five tickets for $1. Each of the latter two classes of tickets have coupons attached which will be accepted in payment of one fare within the city of Milwaukee fare limits, if the order of the Railroad Commission, providing for the sale of thirteen tickets for 50 cents is set aside or vacated in the action now pending. About 81 per cent of revenue from urban traffic is paid in tickets.

Prior to Jan. 18, 1914, the rate of fare beyond the single-fare limits of Milwaukee was 5 cents cash into and through each 5-cent zone, these 5-cent zones having been fixed in previous years by franchise negotiation, trade or voluntary concession and extended through each suburban city or village adjacent to Milwaukee and on the interurban lines beyond. The distances for a 5-cent fare varied from 0.99 to 7.17 miles and were the sources of many complaints. Overlapping fare zones had grown into the system from time to time, due to extension of the city fare limits, annexation of territory, compromise, franchise provisions, etc.

On certain suburban lines reduced rate commutation bearer tickets were sold in blocks at 7½ cents each. These were good for a ride in either direction in the city of Milwaukee, including one 5-cent suburban zone adjacent thereto.

P-CENTER OF GRAVITY OF POPULATION
The Fare from any point within the City of Milwaukee to any Suburban fare point, will be the regular City fare or ticket, plus two cents for each suburban fare zone or fraction thereof.
MINIMUM CASH FARE FOR ANY RIDE 5 CENTS
The Milwaukee Electric Railway & Light Co.

MILWAUKEE ZONE SYSTEM—MAP SHOWING ZONES

The fares charged on the interurban lines were made up by the sum of the various 5-cent zone fares, plus the Milwaukee single fare, transfers and reduced rate city tickets being exchanged for that portion of the ride in Milwaukee from the first fare point to the Public Service Building, located within the business district. Reduced rate round-trip tickets were sold to certain interurban points. The relation between the round-trip rate and the one-way rate was not uniform but varied according to the circumstances which the fare was designed to meet.

---

[*] Paper presented at convention of the American Electric Railway Association, Atlantic City, N. J., Oct. 15, 1914.

COMPLAINTS REGARDING DISCRIMINATIONS IN FORMER RATES AND DISTANCES

With the advent of commission regulation, many complaints were made by patrons and municipalities, alleging discriminations, citing the various instances of disproportionate distances for the same fare, urging extension of single-fare limits and round-trip reduced rates comparable with those in existence on other parts of the lines, etc. Cases had been brought before the commission involving the extension of the Milwaukee single-fare limits to two of the principal suburbs, and a number of other cases were pending, all of which gave evidence of continued controversy and involved much time and expense on the part of both the company and the commission.

Abundant opportunity existed for complainants to present a plausible case. All that was necessary was a diligent search with ruler and map to discover instances where the company was giving longer rides for the same money and then to argue that the complainants were either paying too much or received less favorable treatment and hence were discriminated against. The single-fare zone does not in several instances correspond with the corporate limits of the city. In one case many years ago, real estate owners desiring to subdivide land for sale at a profit undertook to raise $30,000, and actually paid over $20,000, as a subsidy to procure the construction at that time of an extension of one city line some 3 miles into the country, with the apparent understanding that city service at the single fare be extended to the outer terminus. These hopes of rapid development were not realized, and operating deficits still continue to exist due to sparsity of traffic. This condition gave rise to recurrent demands for lower fares from other suburbs. In other cases, franchise conditions inherited in many cases from predecessor companies prescribed fare zones, which gave equal possibilities of unfavorable comparison.

These existing conditions were in their nature beyond the control of the company. Its only defense, aside from considerations of density of traffic, was the very evident fact that the instances cited were not paying expenses. Public policy and the best policy of management required that inequalities be eliminated and that a new uniform system of fares based as far as possible upon scientific principles be substituted for the prevalent system of fares.

Accordingly, in conformity with the suggestion of the Railroad Commission of Wisconsin, the company made formal application, under date of Aug. 15, 1913, requesting that the commission "investigate the rates for suburban and interurban service and by order prescribe such uniform tariffs and schedules of rates as shall be just and proper under the circumstances." All the various cases and petitions before the commission involving reasonableness of the alleged discriminations for suburban and interurban service were consolidated and disposed of in the decision of Jan. 2, 1914. A few citations from the opinion upon the points involved will be of interest.

CITATIONS FROM DECISION

Discriminatory Features of the 5-Cent Zone. "In selling transportation to persons the adopted standard unit of measurement is the passenger-mile—one passenger carried one mile. Although steam lines in general have adhered to this standard, the electric interurban system in many cases have used the so-called 5-cent zone system of rates. This system is merely an extension of the flat 5-cent city fare and has no scientific basis for suburban or interurban operation. The resultant inequalities which exist under this system of rates may well be illustrated by measuring the different fares charged by the unit of measurement—the passenger-mile. No better examples can be cited than can be found upon the suburban and interurban systems involved in the present proceeding."

Discriminatory Features of Overlapping Zones. "Directly due to the inequitable nature of the 5-cent zone system, as outlined in the * * * discriminations of one-way fares, is the practice of granting overlapping zones, special and round-trip rates to favored points. When overlapping zones are injected into the 5-cent zone system we have a rate scheme which places every locality in competition with its neighbors. For instance, it is usually contended that if a company extends the limits of an interurban zone for ½ mile so as to reach a certain locality, and thereby grants a lower fare to this locality to all points through the overlap, it logically follows that the next locality ¼ mile or ½ mile distant should be granted a similar concession. The result is that this necessity of granting overlaps caused the rate schedules to become even more discriminatory, and, carried to its logical conclusion, the entire schedule ultimately must fall to the ground.

"In any equitable system of fares for suburban and interurban service the overlapping zone cannot be justified except under very extreme conditions."

Necessity of Uniform Distance Basis for Fares. "In establishing a revised system of interurban and suburban fares it is fully realized that the present fares will be considerably disturbed in some sections of the territory, but this is not due to the application of any radical or untried theory of rates. It is due principally to the fact that the existing fares * * * do not rest upon any scientific basis but are based upon unequal zone distances and concessions to favored localities. The results of such a schedule are obvious. Invariably one or more localities are built up at the expense of others. Patrons favorably situated are granted extremely low fares, part of the cost of which has to be borne by those less favorably situated and paying excessive rates. With these facts in mind, a revision is here undertaken with the sole aim of removing as much of the discriminations as possible and placing a schedule of fares in force, upon a uniform rate per passenger-mile, which will equalize opportunity for local growth and expansion, insure equitable treatment of individuals and reasonably reserve the amount of traffic upon the various lines."

Basis of Zone System of Fares. "In bringing about uniformity in the suburban fares by applying the distance basis * * * the fares as authorized are placed as near as possible upon an equitable basis by the establishment of consecutive 2-cent zones. * * * This scheme of fares is far less discriminatory than the existing 5-cent zones with the accompanying overlaps. The present system is discriminatory partly because the suburban zones vary all the way from 1.44 miles to 7.17 miles. * * * When cognizance is taken of the fact that 5 cents is charged for these varying distances the inequalities as between suburbs becomes apparent. * * * To remedy these differences it will be necessary to employ shorter zones upon a proper basis. A charge of 2 cents as applied will necessarily raise the low rates and decrease the higher ones."

These changes were immediately made effective upon the entire system with the exception of the longest suburban line, where a reduced trip ticket with an increase of 2½ cents over the present cash fare and 3½ cents over the suburban cash and city ticket fare has been installed for a period of one year in order that the transition to an increased fare operate gradually.

PRESENT SYSTEM OF ZONE FARES—UNIFORM FARES AND DISTANCES

The system of fares established in compliance with the opinion and decision of the commission comprises a "Central" or "Metropolitan District," extending 8½ miles to 9 miles in length and 6 miles in width, bounded on one side by Lake Michigan; the area aggregates approximately 35.5 square miles and contains a population of 400,000. The Metropolitan District conforms substantially to the area within the then city limits, the corporate limits, however, being disregarded as controlling. Within the boundary of the Metropolitan District a single fare is charged irrespective of distance carried. The length of the various lines radiating from the center of gravity of the street railway traffic in the downtown district to the outlying territory and beyond the Metropolitan District into the suburbs, is as shown in Table I.

TABLE I—DISTANCE IN MILES FROM CENTER OF GRAVITY OF TRAFFIC

NOTE.—Line No. 2 has a sixth zone 1.25 miles in length; Line No. 21 has a sixth zone 1.15 miles in length and a seventh zone 1.01 miles in length.

A comparison of the length of these lines and an examination of the map on page 950 will disclose the variation of the boundaries of the Metropolitan District from a true circle. Some of these city lines are through or radial lines extending from the outer limits of the Metropolitan District in one division of the city through the downtown district and continuing on to the outer boundary of the Metropolitan District in another division of the city, and some extend beyond into the suburban territory. Some of the city lines are entirely of the crosstown character and do not approach the center of traffic. The map is similar to that displayed in card form in the cars of the company.

Beyond the limits of the Metropolitan District upon each of the suburban or interurban lines radiating from the city nine lines comprising this system have been divided into geographical zones approximating 1 mile in length, the zone points being placed at principal traffic points where such was possible within reasonable variation in distance from the 1-mile point.

The charge for a ride from any point within the Metropolitan District into or through each such geographical zone is 2 cents in addition to the city fare. For any local suburban haul originating and terminating beyond the Metropolitan District, the fare is computed in like manner as the suburban components of the above rates of fare, the minimum cash fare for any ride being 5 cents.

On the interurban lines extending beyond the limits of the suburban territory the fare charged is 2 cents for each additional mile, the interurban fares being computed to the nearest 1 cent. Where interurban lines pass through the principal outlying cities or subterminals for distances ranging from 2 miles to 3 miles a 5-cent cash fare is substituted for the 2-cent-per-mile rate, thus providing a single 5-cent fare within the city limits of each of the sub-terminals. For "through interurban passenger service" upon all interurban lines, the mileage included within the Metropolitan District of the city of Milwaukee is in every case computed at 4 cents. For passengers riding locally on interurban cars between the Metropolitan District and the outer limits of the suburban service zones, the charge in every case is the same as the rate of fare for suburban service. The rates of fare per passenger for all interurban service between points outside the Metropolitan District of the city of Milwaukee is the difference between the through rates to these points. The through fare between sub-terminals is equal to the sum of the local fares. Non-transferable individual 300-mile mileage books at 1.8 cents per mile, good for the payment of any interurban or suburban fare, with a minimum tear of 5 miles, are sold through conductors on interurban cars. When the cash fare is odd, the next highest fare is torn.

Upon both suburban and interurban lines, children under three years of age are carried free. Children between the ages of three and ten, inclusive, are carried for one-half the full fare. All passengers are entitled to the usual transfer privilege within the single-fare limits of the city of Milwaukee and to transfers upon the several suburban lines, provided, however, that no such transfer shall operate to compel the company to carry a passenger on the suburban lines for less than the regular fare of each 2-cent distance or fraction thereof on each line within which the passenger rides.

When the new fares were placed into effect all abandoned reduced-rate and round-trip tickets outstanding were honored for a period of thirty days, after which they became void upon the cars but were redeemed on demand at a pro rata portion of the original cost.

COMPARISON OF ZONE SYSTEM WITH FORMER RATES

The distances, comparative over all cash rates and resulting rates per adult passenger-mile, on all suburban lines, as measured from the center of gravity of traffic in the Metropolitan District, are contained in Table II.

Reference to the map on page 950 will disclose that the center of gravity of the street railway traffic, marked *T*, coincides closely with the center of population, marked *P*, the former point extending about 3000 ft. in the direction of the business district. The terminus of all interurban lines and of the longest suburban or South Milwaukee line, or the Public Service Building, whose location is marked *P. S. B.*, is also close at hand. In fact, the three focal points—center of traffic, center of population and the terminal building—are within 2900 ft. to 3500 ft. distant from one another.

During various discussions before the commission upon the reasonableness of uniform rates and distances in the suburban territory, an attempt was made to show discriminations in the application of such uniform rates by associating the distance to various suburban points from the Public Service Building rather than from the limits of the Metropolitan District within which the city fare applies for any distance. It will be noted

TABLE II—DISTANCES AND RATES, ETC., FOR FORMER AND PRESENT CONDITIONS

Suburban Line	DISTANCE		Over-all Distance (Miles)	OVER-ALL RATES CITY PLUS SUBURBAN		Number of Suburban Zones, Present Basis (Number)	OVER-ALL RATE CITY PLUS SUBURBAN ADULTS' RATE PER PASSENGER-MILE		Distribution Suburban Revenue, per cent

8. Tippecanoe	3.89	1.53	5.42	5	9	2	0.92	1.66	3.1
9. South Milwaukee....	4.22	7.17	11.39	10	19	7	0.88	1.67	43.5
Weighted average rate per passenger-mile....................							1.18	1.50	100.

NOTE.—These comparisons are based upon a 5-cent cash city fare. The actual average city fare from city tickets and cash was 4.18 cents per revenue passenger for the year 1913.

that the zone distance as determined by the commission is based upon the outer limits of the Metropolitan District rather than with reference to the central points described, although such central points were undoubtedly considered in determining the limits of the Metropolitan District.

With the application of the zone system to the suburban lines, changes in rates became necessary on all interurban lines. The commission found from its computations as to the cost of the interurban service that actual costs justified the establishment of basic rates to yield about 2.75 cents per passenger-mile. "When the conditions prevailing on the interurban system are considered, * * *" it stated, however, "it seems best to place the rate at a lower figure than the cost of service would demand so as to encourage the passenger density with this lower rate to increase sufficiently to bring the revenue to the point where it will bring an adequate return above all expenses."

A comparison of the old and new rates on the interurban lines is shown on the accompanying diagrams. These show clearly the rates on a distance basis, measured from the outer limits of the Metropolitan District, as compared with similar rates as measured from the Public Service Building and rates upon the old 5-cent basis, together with a statement of the number of rates not changed and those increased and decreased by the application of the zone system.

METHODS OF COLLECTION

All city and suburban cars of the company are of the prepayment type, either with semi- or fully-inclosed platforms with folding doors, the latter cars having no bulkheads. Small portable fare boxes are used, except on interurban cars carrying through service. These fare boxes are of light aluminum construction, with wireglass sides exposing the fares to view, and are provided with convenient handle for portable use.

Under the present system of 2-cent suburban zone fare collections, passengers originating at or destined to points within the Metropolitan District pay 5 cents cash or a city ticket, and in addition thereto 2 cents cash or one 2-cent zone ticket for each 1 mile suburban zone into or through which the passenger rides, in the manner hereafter described, the passengers being entitled to one transfer within the Metropolitan District, if requested, at the time fare is paid.

One objection to such a system is that it involves the collection of small increments for added fares with the probable use of a large number of pennies and necessitates care in accurately ascertaining the zone into which outbound suburban passengers had paid their fares.

To meet this problem the company provided for the sale of suburban zone tickets by conductors on the cars. These tickets have a value of 2 cents each, are printed with a broad red band across each face, and are of the same size as the city ticket but are readily distinguished from these. Zone tickets are sold in small quantities at no discount and are good only for one ride into or through any one suburban fare zone. During the last four months the sales of such zone tickets have aggregated 21.8 per cent of the suburban revenues, and their use has practically eliminated the anticipated troubles arising from the collection of fares in pennies. Conductors on city and suburban runs are provided daily with $25 in value of city tickets, $5 in value of 2-cent zone tickets, and provide themselves with $5 in change, an amount which is no different from the change carried prior to the establishment of the zone system.

The problem of checking destination necessitated a change in the regular transfers used upon lines reaching into the suburban territory so as to provide space for the conductor to punch time and zone destination by name to which the passenger has paid fare. In the case of the longest suburban line, comprising seven 2-cent zones, a special zone receipt was necessary because of lack of space on the regular transfer. This form of receipt is issued to all outbound passengers originating within the Metropolitan District except those destined to points within the first 2-cent suburban fare zone adjacent to the Metropolitan District, on all lines except in the case of the longest line. As passengers leave the cars beyond the first zone the receipts are lifted by the conductor and remitted in the usual way.

Outbound passengers may pay regular city fare to the city fare limits and continue their journey into suburban territory upon payment of the necessary additional 2-cent zone fares in cash or zone tickets or may pay through fare to suburban destination when boarding the car. When suburban cars pass from the Metropolitan District to suburban territory, the conductor enters with the portable fare box and collects the suburban fare from the passengers who have not paid through fare to destination, issuing the transfer receipts accordingly. When passengers leave the car beyond the first suburban zone, the receipt is surrendered to conductor who checks destination and collects any deficiency.

Inbound suburban passengers when boarding cars are requested by conductor to make prepayment of through fare to the Metropolitan District and place the amount in the fare box in cash or tickets. No receipts for fare paid are given to inbound passengers, except upon the longest line of seven zones. On this line, when cars pass into the Metropolitan District, the receipts are lifted to check passengers who have paid city fare.

The minimum cash fare for any ride in suburban territory is 5 cents. Two-cent suburban zone tickets are not honored within the Metropolitan District and are not good for the initial ride in suburban territory unless three or more are paid at the same time for each passenger for a continuous ride. Conductors report on trip sheets the actual number of passengers on car entering and leaving the Metropolitan District and, in addition, the number of passengers on and off in each 2-cent zone. This information serves as a basis for the division of earnings.

The collection of fares under this system has worked out satisfactorily and, since the elimination of various experimental schemes, does not now involve delay or congestion. It is also believed to provide means for collection of all fares in a practical manner. On special occasions, such as large crowds at suburban resorts, State Fair and during rush hours when large numbers of workingmen are concentrated at certain points, the collection of fares is facilitated by the use of extra fare collectors for short periods of time, who assist by collecting fares and by loading the large interurban cars usually employed for this service at both ends. In some special cases small portable ticket booths have been employed where through tickets from suburban resorts to the Metropolitan District are sold, thus greatly facilitating the rapid loading of cars. This plan has eliminated the difficulties anticipated at congested points, as a large percentage of passengers purchase tickets at the ticket booths.

MILWAUKEE ZONE SYSTEM—COMPARISON OF OLD AND NEW RATES OF FARE ON VARIOUS LINES

Interurban cars do not carry local city passengers. Such cars stop, however, at frequent points outbound in the city to pick up passengers destined to suburban points and beyond. Inbound cars within the Metropolitan District discharge passengers only. The collection of fares on all interurban cars in through service consists merely in lifting tickets sold at agencies or collecting cash fares and issuing proper receipt therefor.

COST OF SUBURBAN SERVICE

The cost of service for suburban and interurban traffic has not been of controlling importance in the establishment of the rates of fare, as provided in the order of the commission, since, like many suburban and interurban properties, it was evident that any rates of fare which purported to pay a reasonable return upon the investment would be prohibitive and result in decreased traffic. It is of interest to compare, however, the revenues resulting from the operation of the zone system with the costs of furnishing the service rendered.

In the development of the cost of service, the method employed is that used heretofore on the company's properties and consists of separately localizing revenues, operating costs and the value of the tangible property as determined by the commission used and useful for railway purposes. Each of the several lines has been separately treated, and a summary showing the cost of service on the combined lines determined.

Operating expenses are grouped according to the unit with which the expense item varies, and miles of track, car-miles, car-hours and revenue passengers have been used as the unit of apportionment. Depreciation and return upon the investment in tangible property have been computed upon the investment applicable to each suburban line. When assembled these figures constitute an income account for any line and enable the determination of its unprofitableness. The operating expenses were determined from the actual expenses for the first eight months of the year 1914 and the remainder of the year estimated.

These expenses have been grouped as follows:

(a) Under expenses, varying with the car-hour, there are included: wages of conductors and motormen; incandescent lamps for lighting cars; water and supplies for cleaning cars; fuel, kindling and other supplies for heating cars; miscellaneous transportation expenses.

(b) Under expenses varying with the car-mile, there are included: 43.88 per cent of the way and structures group of charges; equipment; lubricating supplies for cars and motors; miscellaneous car service, supplies and expenses.

(c) Under expenses, varying with the miles of single track there are included: the remaining portion of the way and structures group of charges (56.12 per cent).

(d) Under expenses varying with the revenue passengers carried, there are included: superintendence of transportation; wages of miscellaneous car service employees; tickets, transfers, etc.; secret inspection; ticket punches, motormen's tools, badges, etc.; wages of station employees; wages of carhouse employees; miscellaneous carhouse expenses; operation of telephone system; patrol and wreck service expenses; injuries and damages (actual expenditures).

(e) Under power plant expenses, varying with the car-mile, there are included: power apportioned (proportionate cost of power).

(f) As overhead expense there are included: general expense; insurance; stationery; operation of stores department; maintenance of stores department equipment; maintenance of stores department buildings, fixtures and grounds; rent of land, buildings and other property; taxes.

Such expenses have been apportioned as a definite percentage of classes (a) to (e).

(g) Under depreciation there has been included an amount calculated at 4.38 per cent of the reproduction cost new on the suburban lines, being the basis of the amount estimated by the Railroad Commission of Wisconsin in the previous fare case and chosen for purposes of illustration.

(h) Return upon the tangible property has been calculated at 8 per cent. This likewise follows the percentage in the commission's 1914 calculations.

The reproduction cost new of the various lines is based upon the Railroad Commission valuation as of Jan. 1, 1910, to which has been added the property additions made subsequent to that date to bring the valuation in this case to June 30, 1914, for the purpose of determining the cost of service for the year ending Dec. 31, 1914. The physical property has been assigned to the zone or line of which it is a part wherever possible, but such items as land, power plants, rolling stock, etc., have been apportioned on a car-mile or car-hour basis as appeared proper, using operating units for these zones for the year 1914 for determining such apportionment, land being apportioned on the car-hour basis; roadway and paving, transmission and distribution system being directly applied in accordance with the geographical location of this property; power plants, with their buildings and grounds being apportioned on the car-hour basis, and railway stock, with its buildings and grounds being apportioned on the car-mile basis.

The valuations as obtained are approximate. It is believed that the method used is as accurate as can be followed without an extended appraisal. The company is engaged in an extensive valuation of its property, and it is believed when this work is completed the reproduction cost new of the various lines will be materially increased, as the results obtained up to the present time indicate that the old inventories were not complete and that old unit prices used were in many cases too low. Owing to the present lack of returns upon any basis, the correction of these appraisals is a matter of principle rather than of necessity, to substantiate the reasonableness of present earnings.

The combined suburban lines heretofore referred to, and comprising the suburban zone system, show roughly total operating revenues for the year 1914 of $252,672, with an approximate reproduction cost new of $1,191,864. For each $1 of revenue the valuation amounts to $4.71. The actual return upon the reproduction cost new for the year amounts to 1.71 per cent, showing a deficit on the basis of an 8 per cent return of $74,961. There are appended hereto typical detailed tabulations showing the cost of service so determined for several of the suburban lines comprising the zone system, together with a combined statement.

A summary of the cost of service of the suburban lines is shown in Table III.

TABLE III—SHOWING RETURNS OF INDIVIDUAL LINES

	Per Cent of Total Revenue	Operating Revenues	Operating Expenses (Cost)	Deficit	Per Cent of Return
Whitefish Bay Fox Point	9.4	$23,781	$44,163	$20,381	−3.54
North Milwaukee	7.3	18,561	25,806	7,244	−0.51
Wanderer's Rest	2.3	5,732	11,585	5,853	−8.96

South Milwaukee	43.5	109,999	118,059	8,059	+6.25
Combined	100.0	$252,671	$327,632	$74,960	+1.71

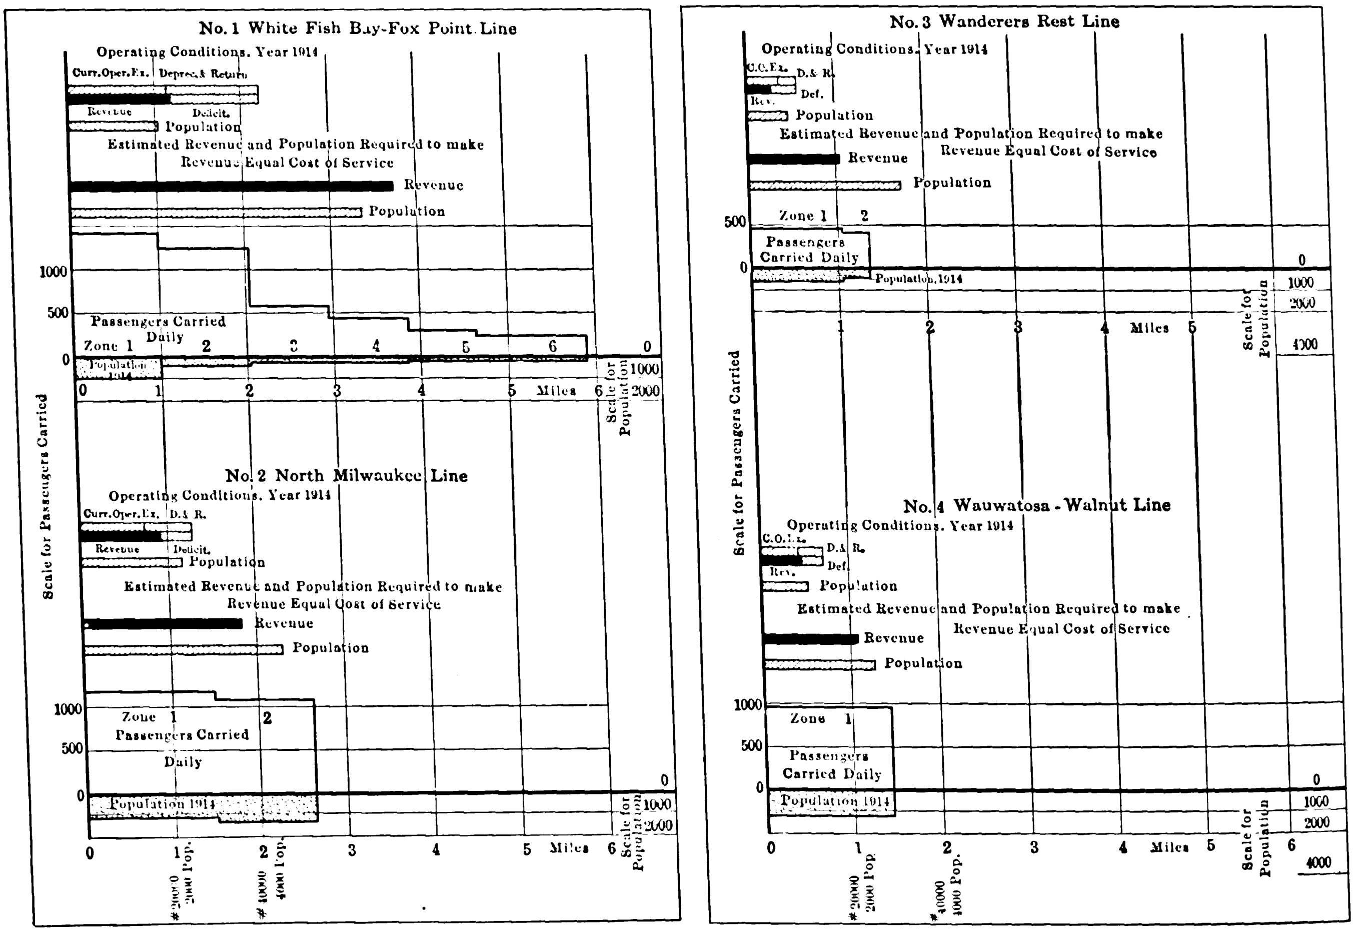
Distance Distribution of Passenger Traffic—Cost and Earnings and Estimate of Additional Revenue Required to Equal Cost of Service

The normal distance distribution of traffic by days from the metropolitan district to the end of each suburban line by zones, determined by the use of conductor's trip sheet records, the tributary population by zones, the revenues, current operating expenses, depreciation and return and deficit by lines are graphically shown on charts, which illustrate the results of the computations of the cost of service.

The unit costs per car-mile, per car-hour, miles of single track, together with revenue passenger and passengers per mile, population and average rides per capita for the year 1914, are shown in Table IV for each of the suburban lines computed from the data heretofore referred to.

Table IV—Comparison of Revenue and Other Data for the Various Lines

Line	Revenue per Car-Hour	Revenue per Car-Mile (Cents)	Revenue per Revenue Passenger (Cents)	Revenue per Mile Single Track	Miles of Single Track	Passengers per Car-Mile	Tributary Population	Annual Rides per Capita
1	$2.39	19.83	4.85	$2,591	9.18	4.1	2,140	229
2	2.43	22.09	4.04	5,396	3.44	5.5	2,334	197
3	1.10	17.83	4.02	3,899	1.47	4.4	960	148
4	1.55	30.42	3.02	6,503	1.44	10.1	1,097	282
5	3.13	31.88	3.79	9,719	2.59	8.4	2,330	286
6	2.82	30.55	3.50	8,909	3.60	8.7	3,777	243
7	2.95	24.48	3.79	4,500	4.48	6 5	1,760	302
8	1.17	12.25	2.84	4,774	1.64	4.3	1,050	262
9	4.05	28.88	6.43	7,402	14.86	4.5	10,642	161
Combined	$2.83	25.83	4.59	$5,917	42.70	5.6	26,090	211



MILWAUKEE ZONE SYSTEM—RESULTS ON LINES 1, 2, 3 AND 4

Assuming that the valuation, rate of return and depreciation, together with the per cent of overhead expense burden to current operating expenses, remain the same as in the 1914 statement and that no reduction in the service heretofore operated be made on any suburban line, the additional revenue and passengers required on each line to justify the present investment and make revenues just equal the cost of service, are estimated as shown in Table V.

The additional revenue and passengers required as shown in Table V have been determined on an assumption that the current operating expenses by lines with growth in business necessary to earn a reasonable return will approximate 60 per cent of the total cost of service. The number of passengers has been determined from the additional revenue thus required on the basis of the average fare per passenger for the year 1914, for each line separately.

Table V—Data for 1914 and Additional Revenue and Passengers Required in 1915 to Make Revenues Equal Cost of Service

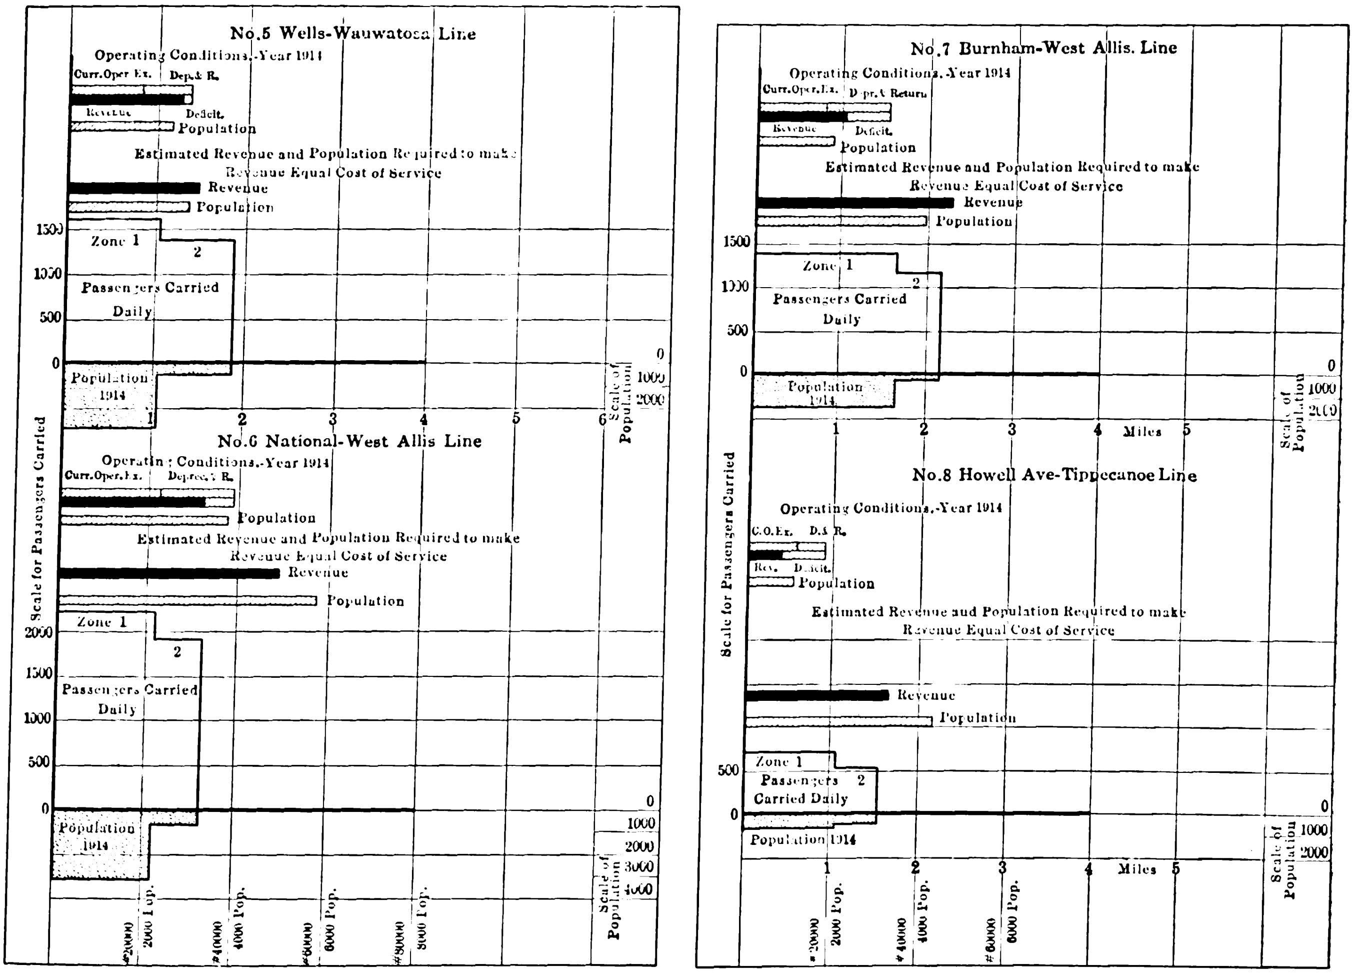
Line	Year 1914: Depreciation and Return, per Cent to Total	Year 1914: Current Operating Expenses, per Cent to Total	Year 1914: Amount of Deficit	Additional Revenue Required, 60 per Cent Basis	Additional Passengers Required	Revenue Passengers, 1914	Per Cen Additional Passengers Required
1	49.8	50.2	$20,381	$50,952	1,050,557	490,475	214.
2	41.0	59.0	7,245	18,113	448,341	459,072	98.
3	37.0	63.0	5,854	14,635	364,055	142,536	255.
4	38.0	62.0	4,866	12,165	402,814	309,787	130.
5	37.2	62.8	1,666	4,165	109,894	663,343	17.
6	41.0	59.0	6,618	16,545	472,714	917,307	52.
7	49.5	50.5	10,206	25,515	673,087	531,776	127.
8	38.0	62.0	10,065	25,163	886,211	275,234	322.
9	48.0	52.0	8,059	20,147	313,328	1,710,086	18.
Combined lines..	45.0	55.0	$74,960	$187,400	4,721,001	5,499,166	85.8

The causes for any differences in the distribution of the traffic, population and rate of return by lines may be traced to the characteristics of the several lines:

(1) The Whitefish Bay-Fox Point line passes through a residential district after leaving the metropolitan district, through the first four zones or to the north lim-

its of Whitefish Bay. The first zone is entirely within the limits of the village of East Milwaukee, which had a population of 707 in the 1910 census. The second, third and fourth zones lie entirely within the limits of Whitefish Bay, which had a population of 542 in the 1910 census. The resort at this location also contributes a considerable amount of summer business. Both of these villages have increased considerably in population since the last census. From that point north the territory is sparsely settled and is mainly farming land, except that there is a country club at Fox Point and this line has much summer picnic traffic.

(2) On the North Milwaukee line, the first zone after leaving the metropolitan district first passes through vacant property and into a fairly well settled residential district. The north end of this zone and the second zone lies entirely within the village of North Milwaukee, a manufacturing suburb, having a population of 1860, according to the 1910 census.



MILWAUKEE ZONE SYSTEM—RESULTS ON LINES 5, 6, 7 AND 8

(3) Both zones of the Wanderer's Rest line pass through a very sparsely settled farming district. Wanderer's Rest Cemetery at the end of the line creates some Sunday traffic. This is a portion of a line it was originally proposed to extend into interurban territory.

(4) On the Walnut Street-Wauwatosa line the single zone lies entirely within the residential suburb of Wauwatosa and is used in connection with Zones 1 and 2 of Line 5. This suburb had 3346 people in 1910.

(5) On the Wells Street-Wauwatosa line the first zone lies entirely within the city of Wauwatosa. Part of the second zone of this line extends beyond the city limits of Wauwatosa to the county farm.

(6) Both zones, National-West Allis line, of this line lie entirely within the manufacturing and suburban city of West Allis. This suburb had a population of 6645 in the 1910 census. The second zone is entirely in the residential portion of the city.

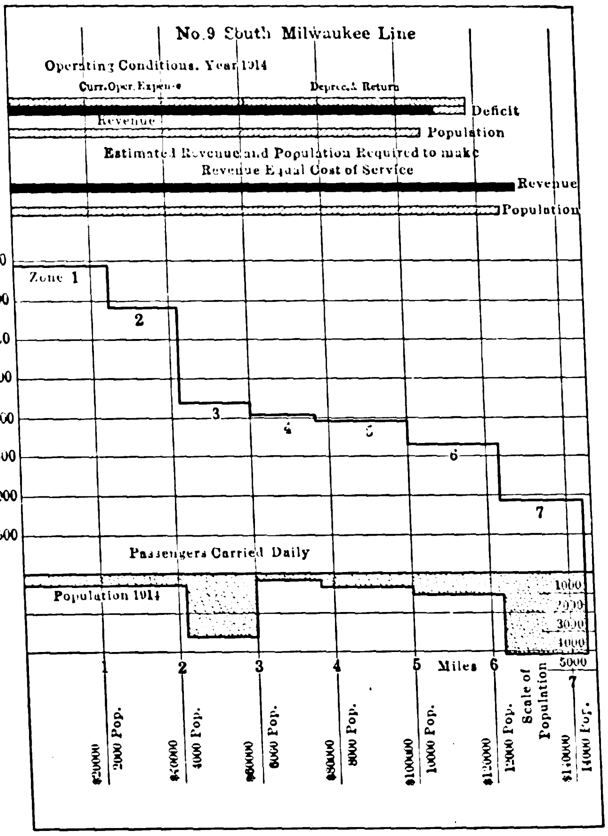
(7) Both zones of the Burnham-West Allis line lie entirely within the city of West Allis, but the line passes entirely south of the thickly settled portion of that city and, therefore, does only a small local business.

(8) Both zones of the Howell Avenue-Tippecanoe line are outside of the limits of any municipality, but the district is only fairly well built up with residences.

(9) On the South Milwaukee line the first zone passes through a residence district which gradually thins out. There is one small college located within this zone. A portion of the second zone has the same characteristics of the first zone, but passes through ½ mile of vacant property and enters partly into the manufacturing section of the city of Cudahy. The third zone lies entirely within the city of Cudahy. The fourth zone lies partly within the outskirts of Cudahy and partly in a sparsely settled district adjacent. The city of Cudahy had a population of 3691 in the 1910 census. The fifth zone lies partly within the above district and partly within the manufacturing city of South Milwaukee. This city had a population of 6092 in the 1910 census. The sixth zone lies entirely within the central portion of the city of South Milwaukee. Both branches of the seventh zone also lie entirely within the city of South Milwaukee but reach into the thinly populated sections on the outskirts of that city.

EUROPEAN ZONE SYSTEM

An opportunity was presented to analyze and tabulate certain data relating to the application of the street railway zone system and methods of collecting fares in a number of foreign cities. The information from which this tabulation was prepared was obtained from the files of the secretary of the American Electric Railway Association, consisting of voluminous letters and exhibits received from various foreign companies in response to a circular letter which was sent out by the secretary under date of Sept. 11, 1912, at the request of the committee to study the best methods of collecting and accounting for variable rates of fare. The material was arranged, translated and abstracted by a special committee appointed from members of the Milwaukee Company Section No. 1, A. E. R. A. An abstract of the report for each city and a tabulation showing the summary of the results obtained is appended hereto. Since the general practice of all the cities is very similar as to methods of collecting and accounting for fares, the abstract for the city of Leeds, England, which is appended separately, is typical of all. The principal differences in details of practice are clearly shown in the tabulation.



MILWAUKEE ZONE SYSTEM—RESULTS ON LINE 9

A study of the report indicates that:

(1) The zone system is used in all of the sixteen European cities from which reports were received.

(2) The length of ride and rates of fare are varied, but considering the purchasing value of money, the rates are generally higher than the fares in this country and higher than those obtaining in Milwaukee.

(3) Small increments in the fares for additional distance traveled are provided throughout the congested or central districts as well as the outlying districts.

(4) The rates provide much higher fares for the distance equivalent to the boundary of the central zone than exist in Milwaukee and probably other American cities. The same is noted for total fare to other zones.

(5) A marked similarity in the methods for collecting and recording fares in all of the cities is noted. In every instance receipts are given for the fares when collected and these receipts are subject to check by inspectors who board cars at unexpected intervals.

TABLE VI—COST OF SERVICE ON THE MILWAUKEE ELECTRIC RAILWAY & LIGHT COMPANY COMBINED SUBURBAN LINES (1-9 INCLUSIVE), YEAR ENDING DEC. 31, 1914
(From Limits of Metropolitan District to Terminus of Suburban Service)

	Amount	Number of Units	Cost per Unit
Operating revenues (total)	$252,671	....	....
Operating expenses (total)	327,632	....	....
(a) Costs varying with the car-hour	49,776	88,982	$0.5594
(b) Costs varying with the car-mile	25,426	977,955	.0260
(c) Costs varying with the miles of single track operated	18,103	42.70	423.9658
(d) Costs varying with the number of revenue passengers carried	28,598	5,499,616	.0052
(e) Costs of electrical energy-car-mile	22,297	977,955	.0228
(f) Administrative and overhead expense burden	35,877	Per cent (a) to (e)	24.88 per cent
(g) Depreciation reserve[1]	52,203	....	....
(h) Return upon tangible property[2]	95,349	....	....
Deficit	74,960	....	....

[1] 4.38 per cent on $1,191,864.
[2] 8 per cent on $1,191,864.
Actual return upon reproduction cost new ....1.71 per cent
Reproduction cost new, $1,191,864, is based upon Railroad Commission valuation as of Jan. 1, 1910, corrected to June 30, 1914. Earnings and expenses including all service operated are actual for the first eight months of the year 1914; remainder of year estimated.

(6) The issue of transfers generally carries extra charge and free transfers are exceptional.

(7) Special fares for workmen and special ticket rates are common, but limited to restricted hours, usually issued before 7:30 a. m. and good for return before 8 p. m.

The close similarity in certain features of operation of the zone system in all of the cities is quite marked. The information does not disclose whether this similarity has arisen through precedent or whether the experience of all the companies has gradually led to the adoption of the same methods through the process of cut and try. The limited means of working classes and the consequent necessity for strict economy have undoubtedly been the main factors in developing short zones and small units of fare at the expense of congestion and higher rates of fare to others in the outlying districts. As the information procured was limited to rates of fare and methods of collection and did not contain financial statements or other traffic statistics, no conclusion can be drawn with respect to the cost of the service.

It is certain, however, that valuable lessons can be learned through studying the methods of our careful, painstaking neighbors, and the adoption of certain details of the European methods in this country would undoubtedly prove advantageous.

ADVANTAGES TO BE DEVELOPED BY THE ZONE SYSTEM

At the risk of repeating statements heretofore made on this subject, the zone idea is based upon the assumption that it is more desirable to maintain the single-

TABLE VII—COST OF SERVICE ON OAKLAND-DELAWARE AVENUES, WHITEFISH BAY AND FOX POINT SUBURBAN LINE (1), YEAR ENDING DEC. 31, 1914
(From Limits of Metropolitan District to Terminus of Suburban Service)

	Amount	Number of Units	Cost per Unit
Operating revenues (total)	$23,781.97	....	....
Operating expenses (total)	44,163.42	....	....
(a) Costs varying with the car-hour	5,557.08	9,934	$0.5594
(b) Costs varying with the car-mile	3,117.66	119,910	.0260
(c) Costs varying with the miles of single track operated	3,892.01	9.18	423.9658
(d) Costs varying with the number of revenue passengers carried	2,550.47	490,475	.0052
(e) Costs of electrical energy-car-mile	2,733.95	119,910	.0228
(f) Administrative and overhead expense burden	4,441.37	Per cent (a) to (e)	24.88 per cent
(g) Depreciation reserve[1]	7,737.84	....	....
(h) Return upon tangible property[2]	14,133.04	....	....
Deficit	20,381.45	....	....

[1] 4.38 per cent on $176,663.
[2] 8 per cent on $176,663.
Actual return upon reproduction cost new ....3.54 per cent deficit
Reproduction cost new, $176,663, is based upon Railroad Commission valuation as of Jan. 1, 1910, corrected to June 30, 1914. Earnings and expenses including all service operated are actual for the first eight months of the year 1914; remainder of year estimated.

TABLE VIII—COST OF SERVICE ON WELLS STREET-FARWELL AVENUE, WAUWATOSA SUBURBAN LINE, (5) YEAR ENDING DEC. 31, 1914
(From Limits of Metropolitan District to Terminus of Suburban Service)

	Amount	Number of Units	Cost per Unit
Operating revenues (total)	$25,172.10	....	....
Operating expenses (total)	26,837.83	....	....
(a) Costs varying with the car-hour	4,495.34	8,036	$0.5594
(b) Costs varying with the car-mile	2,053.09	78,965	.0260
(c) Costs varying with the miles of single track operated	1,098.07	2.59	423.9658
(d) Costs varying with the number of revenue passengers carried	3,449.38	663,343	.0052
(e) Costs of electrical energy-car-mile	1,800.40	78,965	.0228
(f) Administrative and overhead expense burden	3,208.59	Per cent (a) to (e)	24.88 per cent
(g) Depreciation reserve[1]	3,797.28	....	....
(h) Return upon tangible property[2]	6,935.68	....	....
Deficit	1,665.73	....	....

[1] 4.38 per cent on $86,696.
[2] 8 per cent on $86,696.
Actual return upon reproduction cost new .... 6.08 per cent

Reproduction cost new, $86,696, is based upon Railroad Commission valuation as of Jan. 1, 1910, corrected to June 30, 1914. Earnings and expenses including all service operated are actual for the first eight months of the year 1914; remainder of year estimated.

fare point at a constant or symmetrical distance from the center of traffic than to extend single lines upon the basis of the cost of separate services to points which are not symmetrical, to the other single-fare zones. The writer has stated in a previous memorandum: "The cost of street railway service is a function of and more or less directly proportional to the distance passengers are carried. With the extension of the city fare zone into outlying territory the average length of ride increases and, correspondingly, the cost of carrying a passenger. In any system a limit must sooner or later be reached where the added haul is supplied at less than cost."

If the Metropolitan District, constituting the city fare limits, shall be determined at points that are equitable for the city as a whole and is approximately symmetrical with respect to the center of traffic, in order to avoid opportunities for claims and discriminations as between different sections of the suburban territory, a distinct advantage is developed by the application of the zone system hereinbefore described.

Such a system eliminates differential fares which are extremely difficult to avoid, as well as discriminatory distances for the same fare, and permits of the substitution of fares on a distance basis substantially the same for all communities. It permits of small increments in the way of added fares for small increments in distances. It equalizes opportunity for local growth and extensions equitably between communities and will avoid the complaint of one locality being built up at the expense of another. It will relieve congestion and ultimately establish a more uniform distribution of population than seems possible under the old flat rate system of longer fares for varying distances wherein development clusters above the city fare limits.

The system is flexible inasmuch as it lends itself to further extensions from time to time along what are now interurban lines, as density of business increases.

Opposition to the zone system developed from those whose fares were increased. Some had difficulty in understanding that the State Supreme Court had held that the Railroad Commission had power to modify rates prescribed in franchise grants. The situation developed an interesting aspect of the differences from a popular viewpoint between downward and upward "regulation."

TABLE IX—COST OF SERVICE ON OKLAHOMA-CUDAHY-SOUTH MILWAUKEE SUBURBAN LINE (9), YEAR ENDING DEC. 31, 1914
(From Limits of Metropolitan District to Terminus of Suburban Service)

	Amount	Number of Units	Cost per Unit
Operating revenues (total)	$109,999.88	....	....
Operating expenses (total)	118,059.17	....	....
(a) Costs varying with the car-hour	15,208.96	27,188	$0.5594
(b) Costs varying with the car-mile	9,902.18	380,853	.0260
(c) Costs varying with the miles of single track operated	6,300.13	14.86	423.9658
(d) Costs varying with the number of revenue passengers carried	8,892.45	1,710,086	.0052
(e) Costs of electrical energy-car-mile	8,683.45	380,853	.0228
(f) Administrative and overhead expense burden	12,188.01	Per cent (a) to (e)	24.88 per cent
(g) Depreciation reserve[1]	20,125.35	....	....
(h) Return upon tangible property[2]	36,758.64	....	....
Deficit	8,059.29	....	....

[1] 4.38 per cent on $459,483.
[2] 8 per cent on $459,483.
Actual return upon reproduction cost new .... 6.25 per cent

Reproduction cost new, $459,483, is based upon Railroad Commission valuation as of Jan. 1, 1910, corrected to June 30, 1914. Earnings and expenses including all service operated are actual for the first eight months of the year 1914; remainder of year estimated.

MERGING OF URBAN, SUBURBAN AND INTERURBAN TERRITORY

From a territorial viewpoint, ordinarily the city merges into its next adjacent suburb without sufficient changes in the character of community improvements to enable one to determine that he is passing beyond the bounds of one municipal jurisdiction into those of another. The outer limits of suburban communities usually possess little that distinguishes them from the rural community into which they merge. Interurban lines are actually built or operated as extensions of suburban lines, which in turn are extensions of city lines. It is difficult, if not impossible, accurately to define urban, suburban and interurban territory because they merge into one another as day into twilight and night. In fact, it is questionable whether such definition is either desirable or necessary for electric railway purposes.

We have previously indicated that the selection of the suburban and interurban fare problem seems, from a practical viewpoint, to require that street railway fares be fixed so that they will vary more or less closely with the distance traveled, that a central district is necessary to promote more semblance to conditions under which American cities have been built up, and that short zones beyond merge into each other without confusion.

The problem of regulation of rates presents similar

TABLE X—ABSTRACT FROM REPORT ON ZONE SYSTEM OF STREET RAILWAY FARES AND METHOD OF COLLECTION OF LEEDS CORPORATION TRAMWAYS, LEEDS, ENGLAND

(This abstract is substantially typical of the practice prevailing for the sixteen European cities referred to in the tabulation.)

Fares:
  Rate:
    ½ mile for ½d.
    2 miles for 1 d.
    3 miles for 1½d.
    4 miles for 2 d., etc.

Workmen's Fares:

Before 7:45 A.M., the rate is half of the ordinary fare. By purchasing a return ticket at the same time a passenger can return over the same section of route as that traveled over in the morning any time after 12 o'clock noon on the day of issue.

Overlapping Fares:

These are in operation and are on the same basis as the ordinary fares.

Collection and Operation:

Conductors upon leaving the depots are supplied with tickets, a punch and way-bills. There are way-bills for each route or line and a total way-bill. The total way-bill shows the number of tickets at the different values (½d, 1d, 1½d, etc.) supplied to the conductor as well as the punch number. This is signed by him as a receipt of punch and tickets. The conductor accepts only cash or tokens (the latter are issued to large employers of labor, etc., at face value only) in exchange for tickets. Each passenger receives a ticket with the value marked thereon and punched opposite to the stage to which he is entitled to travel.

A number of inspectors are engaged for the purpose of checking cars at different points and seeing that all passengers have properly numbered and punched tickets.

No transfers are issued.

Children under twelve years travel at half fare. Children under fifteen going to and from school also travel at half fare.

Accounting:

After completing a day's work the conductor must hand in cash and tickets equivalent to the amount of tickets he received when starting out. He locks his punch and places it in his box, which is sent to head office. The ticket-room staff examines the ticket boxes returned and enters the amount of tickets sold on the total way-bills, which are then forwarded to the punch room where the punch register is compared and added to the way-bill. The conductor's journey way-bills and receipts are then compared with the total way-bills. The number of tickets sold must correspond with the number registered on the punch. The punch has a bell attachment which rings each time it is operated.

General:

Route mileage	70 miles
Number of cars	292
Passengers carried year ending March 31, 1912	86,021,943
Population served (approximately)	550,000

Fare Boxes and P. A. Y. E. Method:

No fare boxes are used and the P. A. Y. E. system is not made use of.

TABLE XI—FARE STATISTICS FOR SIXTEEN EUROPEAN CITIES, COMPILED FROM CIRCULAR LETTER SENT OUT BY AMERICAN ELECTRIC RAILWAY ASSOCIATION IN 1912

County and City	Company	Statistics	Length of Zones (Miles)	Fare per Zone (Cents)	Special Rates	Remarks
Various cities in Great Britain.	British Electric Traction Company.	400 miles of route..........	0.23 to 0.5	0.5 to 1 minimum	Workmen's tickets.	No transfers mentioned.
Birmingham, England.	Birmingham Corporation Tramways.	Single track mileage, 101.46; route mileage, 60.3; 461 cars; passengers per annum, 132,000,000 (25 per cent workmen's rates); revenue, $2,721,600; population served, 850,000.	2.34 3.08 4.11	2 3 4	Workmen's return fraes: 2.71 miles—2 cents 4.68 miles—3 cents 6.15 miles—4 cents 8.22 miles—5 cents	Workmen's return fare gives reduced rate for return from any trip started before 7 A.M. on same day. No transfers mentioned. Cash only tender except workmen's tickets.
Bradford, England.	Bradford City Tramways.	Miles of route, 56; miles of single track, 100.67; number of cars, 242; population served, 337,000.	1.6	2	Workmen's tickets.	No transfers.
Croydon (Suburb of London), England	South Metropolitan Electric Tramways & Lighting Company, Ltd.	Three routes totaling approximately 13 miles.	1 1.5 2.5 3 4 4.5 5.5	2 3 4 5 6 7 8	No reduced rate tickets.	Zones are fixed and overlap every ½ mile. No transfers.
Leicester, England..	Leicester Corporation Tramways.	Miles of single track, 19.3; number of cars, 140; passengers carried per annum, 31,314,360; revenue, $633,666; population served, 227,242.	2.18	2	None mentioned.	Universal 2-cent fare except on two lines where 4 cents are charged. Transfer stages, where fare is 2 cents, are used.
Leeds, England....	Leeds Corporation Tramways.	Miles of route, 70; cars, 292; passengers carried per annum, 86,021,343; population served, 550,000 (approximate).	½ 2 3 4	1 2 3 4	Workmen's tickets, one-half of ordinary rate.	No transfers. Before 7:45 A.M. rate is one-half of ordinary fare. Return ticket purchased at same time permits return over same section of route any time after 12 M. on day of issue. Overlapping fares in force.
London, England...	London United Tramways.	Number of cars, 340; track mileage, 55.2; passengers carried, 62,547,128.	2¼ 3 4½ 5¼ 6	2 3 4 5 6	None mentioned	No transfers except in case of two short feeder lines.
Aberdeen, Scotland.	Aberdeen Corporation Tramways.	None given	2-5 Center of city to any terminus. Across city.	1 2 4	Season tickets.	Three months' season ticket costs $3 for 700 yd. 12 cents extra for each additional 100 yd. No transfers.
Cardiff, Wales.....	Cardiff City Corporation.	Miles of single track, 33; number of cars, 130; passengers carried, 1911, 2,586,421; population served, 183,000; revenue, 1911, $610,500.	1.44 1.99 2.72 3.33 4.00 4.78	2 3 4 5 6 7	Workmen's tickets.	Transfers as understood in America not used. Transfers used which permit people to ride one-half mile and take another car in another direction, tendering transfer ticket in payment.
Glasgow, Scotland..	Glasgow Corporation Tramways.	None given.	2.28	1	None.	No transfers.
Halifax, Nova Scotia	Halifax Corporation Tramways.	None given.	.35 1.35 2.49 3.73 5.05 6.30 7.64	1 2 4 6 8 10 12	Workmen's tickets: 2.70 miles, 2 cents 4.99 miles, 4 cents 7.47 miles, 6 cents 10.11 miles, 8 cents 12.61 miles, 10 cents 15.29 miles, 12 cents	Transfers good for 1.7 miles cost 2 cents.
Paris, France.......	Paris Tramways.	Miles single track, 52.7; passengers carried, 1911 in city, 61,183,000; out of city, 20,474,000; city receipts, $1,407,088; out of city, $347,203.	Suburb Section 1.6 1.94 City Section 0.62 to 2.36 One section Two or more sections	 2 or 1[a] 3 or 2 3 or 2[a] 4 or 3	Reduced fare in morning hours.	Double fare is charged late at night. No transfers are used.
Brussels, Belgium..	Brussels Tramways.	City double track mileage, 64.48; suburban double track mileage, 14.88; passengers carried in 1911, 119,240,102; cars, 610.	0.93 minimum 1.80 maximum on line. Suburban 0.93 minimum each extra 0.47 mile	2 3 2 1	....	Transfers cost 1 cent per 0.93 mile or less on section line; or 2 cents for greater distance.
Berlin, Germany...	Greater Berlin Street Railway.	Comprises Berlin, Charlottenburg and north, south and west Berlin suburban lines.	None given	2½–5	Monthly passes are sold. Cost varies with number of lines on which used.	Loads are limited except in the event of more than normal travel.

Double tickets are issued for 10 cents, for which two 7½-cent rides can be had.	No transfers.

NOTE.—[a], Fares given in first column for Paris are first-class fares; in second column are second-class fares.

aspects. It seems improper that an arbitrary line should be drawn attempting to mark the end of urban territory and the beginning of suburban territory, or the end of suburban and the beginning of interurban territory. Were such a line drawn, its location cannot be permanent on account of the changing character of the development of the community. If no such arbitrary line can be properly drawn, it follows that there is little logic in drawing a line beyond which the profits, if any, arising from city operation shall not be extended.

The extension of the city fare into suburban communities for the purpose of distributing population and lessening congestion presupposes the existence of suburban lines already built or whose construction is contemplated. The only inducement that can ordinarily be offered for the construction of a suburban extension is that such construction will insure the permanence of the city fare.

Interurban lines open up additions to suburban territory and make interurban territory more directly and conveniently tributary to the suburban and central city. They thus share in the same responsibilities and partake of the same relations as exist between suburban lines and the city lines of which they are extensions.

If these statements are true, it logically follows that the profits of the city lines should be extended not only over their suburban extensions but also over the latter's interurban extensions. Such a policy would seem to do injustice to no one or group of individuals, and when properly applied should result in the gradual extension of electric railway facilities so much desired by rural communities. In fact, the application of such methods through the medium of regulation by commissions would do far more for the development of communities than many other schemes now apparently regarded as of great importance by legislators.

The results of the present computations as to the cost of service of the suburban lines on the Milwaukee company's property corroborate similar figures for prior years and lead to the conclusion that such deficits must be made up of surplus from urban traffic. A study of the cost of service on the suburban lines indicates that such lines, taken by themselves, are not self-sustaining.

It is believed certain that the most desirable plan is a consistent application of the zone system to the suburban lines, based approximately upon the principle of uniform fares for uniform distances, coupled with a central metropolitan district within which a unit fare is charged sufficient to absorb any suburban deficits and still give a reasonable return upon the entire investment. Such a plan will eliminate discrimination, equalize opportunity for local growth and expansion, relieve congestion and ultimately produce a more uniform distribution of population.

The zone system herein described has been demonstrated to be capable of operation in practice equally, if not more, free from the usual complications of fare collections.

SUMMARY AND CONCLUSIONS

The following brief conclusions may be drawn from the study which has been made of the zone system of fares as practically applied in Milwaukee:

(1) An analysis of the data herein set forth indicates that suburban street railway traffic is not in itself profitable when viewed from the standpoint of the investor, the public service corporation and the regulating commission.

(2) The present community development of most American municipalities is such as to prevent in a practical way the installation of a system of fares which will result in reasonable returns upon suburban lines.

(3) The future profitableness of suburban lines must lie in the restriction of the allowable ride for a single fare and the gradual application to the extended metropolitan area of a zone system somewhat along lines described herein. No difficulties are encountered in the practical operation of such system and the American public will eventually recognize the equity of such a plan.

The Daily Issues

A letter from a subscriber to this paper received on Monday of this week says: "I have just returned from the Atlantic City convention, and after what I saw there, it is impossible to do anything but send my subscription for the coming year. Your part of the exhibit was great, and I feel that I must read every issue of your journal during the coming year." This letter and inquiries at the convention in regard to the method in which the daily issues were published last week suggest that a brief account of the plan followed would be of interest.

The issues for Tuesday, Wednesday, Thursday and Friday of the daily issue of the ELECTRIC RAILWAY JOURNAL were printed in Philadelphia, that of Saturday was printed in New York. Philadelphia was chosen because New York was too far away and the printing facilities in Atlantic City were not adequate for the work. The manuscript was sent to Philadelphia by special messengers during each day up to about seven o'clock, and the news thereafter was transmitted by telephone directly to the printing office. Twenty-one persons were brought on from the New York or branch offices of this paper to assist in this work. Part of this force remained continuously in Philadelphia. The others worked in Atlantic City, and one or more of the editors went to Philadelphia each night to read the final pages.

The force required to carry the manuscript to Philadelphia and that in the printing office working exclusively on the daily issues consisted of about forty men and boys, making altogether about sixty-one persons engaged directly on the work. The forms were usually ready for the press about midnight, and enough copies were printed quickly to supply the needs in Atlantic City. More time was taken to print the rest of the edition, but all of the sheets were sent to New York in time to be bound and mailed to the regular subscribers on the day of issue.

The expenses of publishing a paper under these conditions and in a rented printing office amounted to considerably more than if the daily issues had been published in New York, and only a portion of this expense was covered by the advertising printed in the daily issues. The remainder represents the contribution of the ELECTRIC RAILWAY JOURNAL to the success of the convention in supplying a prompt and reliable report of it to the railway men at Atlantic City and at home.

Industrial Welfare and Efficieny Conference

In accord with the unanimous vote of the first Pennsylvania Industrial Welfare and Efficiency Conference held in Harrisburg last year, John Price Jackson, Commissioner of Labor and Industry, has issued a call for a second conference to be held in the state capitol at Harrisburg on Nov. 17, 18 and 19, 1914. This conference is held under the auspices of the Pennsylvania Department of Labor and Industry and the Engineers' Society of Pennsylvania. The purpose of the conference is to enable the employers and employees together to work out the great problems before them with reference to increasing the welfare of the employees and the prosperity of the industries.

Appraisals of Ohio Public Utilities

The Joint Committee on Valuation for Ohio Public Utilities Formulates General Principles for Guidance of Companies in Making Inventories and Appraisals as Required by Commission Regulation in that State

On March 19, 1914, the Ohio Public Utilities Commission issued Order 176 and on April 25, 1914, a supplemental order, both calling for inventories and appraisals of the property (owned, operated or leased) of all public utilities in the State. At a meeting on Aug. 14, 1914, of representatives of the various utilities in the State, a committee was appointed to formulate principles applicable to all utilities under the commission's rulings. The members were as follows: Robert Lindsay, chairman, vice-president and general manager Cleveland Electric Illuminating Company; Frank C. Dunbar, district attorney American Telephone & Telegraph Company; Allard Smith, general manager Cleveland Telephone Company; Rollo R. Stevens, Ohio State Telephone Company; J. C. Martin, president Ohio Water Works Association; F. W. Coen, vice-president and general manager Lake Shore Electric Railway, and M. B. Daly, president East Ohio Gas Company. This committee, proceeding upon the assumption that the "reproductive cost new, less depreciation" method was the one called for by the commission, recently published its report, which is abstracted below.

INTERPRETATION OF SCOPE OF ORDER

Although the terms "inventory," "appraisal" and "valuation" were used interchangeably in Order 176, the committee felt that the evident purpose was to secure not only a complete inventory of the items of property of each utility, but also a valuation or appraisal of the property. By property was meant not only the plant, in the largest sense of the word, but also the business. To the cost of physical property and overhead charges must be added the cost of establishing the business and any other elements which enter into the total value of the property. The term "net value" used by the commission refers simply to the depreciated value of the physical property without regard to overhead charges or to the business of the utility.

USE TO BE MADE OF DATA

No announcement has been made of the use which will be made of the inventories and appraisals filed with the commission. It has a right in the case of any particular company to proceed at once to make a final valuation or simply to retain the data for future use. In the case of an immediate final valuation, the data already secured would constitute *prima facie* evidence relative to the value of the property as of the date named. The report states, however, that even in the absence of a valuation by the commission, it is possible that an effort might be made to use the inventory and appraisal as evidence against the utility in any proceeding relating to the fixing of rates, capitalization, sale, condemnation, taxation, or any other proceeding that might take place in the future.

PROPERTY USED AND USEFUL

All property, whether or not used and useful, is to be included in the inventory and appraised upon the basis of its reproductive costs as of a certain date. "Used and useful" property embraces the following:

(1) Property regularly in service in the course of operation.

(2) Property not regularly in service, but which, owing to the wide range in demand, is actually needed and used at some time.

(3) Property which of necessity may seldom if ever be used, but which prudence and good management deem essential as a part of the reserve capacity of the plant and as a safety measure to guarantee constant service.

(4) Property which good management and business judgment consider it necessary to acquire in advance of immediate need for the sake of economy, etc.

(5) All other property and property rights devoted to the public use.

The report states that overhead costs should be applied to all classes of property according to their nature, without regard to whether or not such property is used and useful.

REPRODUCTIVE COST NEW

According to the committee report, the cost of reproducing the property of a utility is made up of: (1) the cost of reproducing the plant, and (2) the cost of reproducing the business which was attached at the time of investigation. The reproductive cost new of such property should take into account all physical, municipal, industrial and other conditions existing at the time which affect the cost of labor, materials, engineering, administration, financing and securing of business, together with all other items which enter into the reproductive cost new of the plant and business as an entirety.

The types of units actually in use should be taken and no theoretical substitution should be made of units of a different type which might be capable of rendering equal service. The material prices and labor costs should be fair and reasonable, due allowance being made for market fluctuations and any abnormal conditions. In the case of the latter, fair prices may be determined by means of a trend curve going back far enough so that the trend price would not be materially affected by going still further back. The period for which the trend curve is plotted has no relation to the length of time it would require to reproduce the property.

PERIOD OF THEORETICAL REPRODUCTION

The owner of public utility properties must bear the cost of interest on money expended for reproduction of both plant and business from the time it is raised until such reproduction is complete and also the cost of insurance and taxes over the same period. In order to arrive at the proper amount of interest, insurance and taxes to be added to the reproductive cost, it is necessary to estimate the reasonable period that such reproduction will require. The reasonable period varies for different utilities and properties of different size, and the committee expressed its inability to estimate it at all.

It is stated, however, that there is a general tendency to assume a much shorter period than is actually required. The period should begin when the proposition is first conceived and follow through all the successive steps to completion. The date certain to be taken for the completion of the plant and business should be July 1, 1914, as of which the inventory and appraisal are made, and the period of theoretical reproduction should be such period prior thereto as it would require to complete the plant and business by that date. Although during the earlier part of this period the principal expenditures will be on account of construction, expenditures incurred for establishing business will begin at some time during the period and proceed simultaneously with construction expenditures until the end.

OUTLINE OF INVENTORY

In order to comply with Order 176, the committee believes that the inventory should include:

I. Reproduction cost new of: A. Preliminary work; 1, preliminary investigation; 2, organization of company; 3, cost of financing; 4, franchise. B. Physical plant, consisting of: 1, land; 2, rights-of-way and water rights; 3, buildings; 4, generating or pumping plant, exchange equipment, etc.; 5, distribution and transmission systems, track, etc.; 6, tools, teams, vehicles, etc.; 7, furniture and fixtures; 8, working capital; (a) cash and other quick assets; (b) stores and supplies; 9, other items of physical property. C. Established business: 1, cost of organizing and training operating, selling and clerical forces; 2, cost of selling service; 3, any other costs of attaching business.

II. Any other elements of going value or good-will.

III. All other elements of value.

The foregoing items are more specifically defined in succeeding paragraphs. Preliminary investigation, the report states, should date back to inception, but should exclude promoters' compensation, which should come under organization. Organization should cover promotion, incorporation and other legal expenses, and preparation of stock and bond issues and other documents. Discount on bonds, however, and expenses incident to floating loans should come under cost of financing. Only the amounts actually paid for franchises should be listed.

PHYSICAL PLANT

Under the heading "land" should be given the original cost, including purchase price, condemnation costs, brokers' and attorneys' fees, surveying costs, recording fees, liens on the property, payments for damages to abutting property and cost of grading land when not done in connection with buildings. The date and conditions of acquisition should also be given. The value as of July 1, 1914, should be given for each parcel, with comparative figures for contiguous property, and the authority for such figures. Additional value by reason of present use should be recorded, consideration being given to (1) location with reference to center of distribution, (2) location with reference to transportation facilities, (3) suitability of property for future growth, and (4) any other natural advantage, such as availability of supply of condensing water, etc.

The heading "rights-of-way" should include the cost of reproducing all rights-of-way acquired for the location of poles, wires, cables, conduits, pipe and track, whether such rights-of-way consist of land owned in fee or of easements acquired by permanent grants or through revocable licenses, oral or written. The cost items concerned are the purchase price or award and expenses of condemnation proceedings, the cost of obtaining consents, the salaries and expenses of right-of-way agents and others employed in securing such grants, recorder's fees and all other expenses.

The cost of reproduction of each building owned by the utility should include the preliminary costs and the contractor's charge for reproducing the building. The latter should be based on one or more competent contractors' estimates, which should show quantities and unit prices and take into account proper allowances for delays due to strikes or other causes, contractor's profit and his costs to meet payments prior to final settlement according to the usual plan. In making his estimate the contractor should not omit those elements of cost which, while not apparent in the finished building, are necessarily incurred in connection with its construction. Among such items are demolition of old buildings, excavation, pumping, bracing, protection of streets and adjoining buildings, cost of estimate, traveling, insurance, bond, fees and permits, stair guards and lights, tests, protection of masonry and other work, temporary office, telephone, photographs, sheds, temporary toilets, temporary heat, temporary inclosures, watchmen, omissions and contingencies. Architects' and owners' supervision, unforeseen expenses not included in the contractor's estimate, and the cost of grading, sidewalks, fences, etc., in connection with the building are also elements of the reproductive cost.

The allowance for working capital should be sufficient to care for emergencies and contingencies as well as for the ordinary expenses of operation. It is impossible to lay down any definite rule for estimating the proper amount to be allowed for this item. It must be determined by each utility with regard to its ordinary outstanding indebtedness, its ordinary accounts receivable and accounts payable, its methods of collection, the natural risk of the business and the condition of its credit.

UNIT COSTS

In estimating unit costs it should be remembered that plants are always constructed piecemeal, with consequent greater cost. The following elements, says the committee, enter into the cost of any unit: 1, Cost of unit f.o.b. point of supply; 2, cost of purchasing; 3, cost of inspection; 4, freight switching, expressage and cartage; 5, cost of unloading; 6, cost of preparing unit for use; 7, cost of hauling to point of use, whenever different from point of delivery; 8, shop, storeroom or yard charges; 9, labor; 10, tools and appliances; 11, incidental material; 12, breakage, loss and waste; 13, construction superintendence; 14, employers' liability insurance; 15, public liability insurance.

OVERHEAD CHARGES

The costs which should be allocated to the units have been outlined above under unit costs. Overhead expenses, which should be allotted as a gross sum or apportioned to large groups of units, include legal expenses, administration and supervision, engineering, insurance, taxes and interest during reproduction, contingencies, and omissions and oversights. No fast line of distinction, however, can be drawn between these two classes. Each utility must take care to avoid duplicating in the gross overhead any items which have been allocated to the units. Apportionments among the groups of units may be advisable where one or more of the overhead charges apply in varying percentages to the different groups of units, but caution must be used that apportionments are made correctly.

APPORTIONMENTS

When two or more utilities are operated by a single company or portions of property are used in common, the value of the jointly used property should be apportioned among the various utilities according to the service requirements of each property. Where the utilities are operating in more than one political subdivision, apportionment should be made according to the service requirements of each subdivision or rate area.

In the case of joint ownership of poles, the reproductive cost should be apportioned on the basis of the respective rights. In the event of joint occupancy of poles, the reproductive cost should be apportioned as though the pole were jointly owned, if the occupying company has been granted a permanent right. If the occupying company has a right terminable at the will of the owner, whether on a rental basis or otherwise, and has certain attachments fastened to the pole, the reproductive cost of the owner's property should include the entire reproductive cost of the pole and its own atachments, while the similar cost of the occupying company's property should include the reproductive cost of its attachments and also the reproductive cost to it of securing the permits, contracts, rights-of-way and all other costs involved in reproducing its rights and physical property.

COST OF REPRODUCING THE BUSINESS

The cost of reproducing the business should include all the necessary cost of attaching the business and reproducing the income of the utility as of July 1, 1914. Some of the elements of expense which enter into such cost are as follows: 1, Organizing and training the operating force; 2, organizing the clerical force; 3, organizing and training the selling force; 4, securing customers, including expenses of solicitors, advertising, printing and free inducements; 5, commercial engineering; 6, printing forms, records, books, schedules and directories, and 7, rent of offices.

DEPRECIATION

Inasmuch as Order 176 requires that depreciation be shown, the report briefly explains the straight-line and the sinking-fund methods, but finds both inferior to actual inspection. Attention is called to the distinction between depreciation and depreciation reserve, the latter representing an amount accrued out of earnings or set aside out of surplus in anticipation of the occurrence of depreciation. In the words of the report, "It is important to note that neither the amount in the depreciation reserve nor the amount which ought to be in such reserve is in any way a measure of the depreciation or loss of value which has already taken place. nor does it afford a measure of the rate at which depreciation or loss of serviceability will occur in the future."

There is no direct connection or relation between the depreciation of any physical units of property and the preliminary and overhead costs which pertain to the property as a going concern. For instance, if some poles or sections of rails, cables or conduit depreciated so that they must be replaced, it does not follow that the values resulting from general engineering, legal, financing, organization and other such costs, have deteriorated to the same extent. The opinion of the committee is that depreciation in preliminary and overhead costs, if it exists at all, is so small that it is impracticable to compute it, and that the utilities are justified in ignoring it in making up their inventories.

OTHER METHODS OF VALUATION

In conclusion the committee points out that reproductive cost new less depreciation is not the only evidence of the value of a utility, and recommends that the following clause be inserted on the last sheet of the inventory above the signature:

"This inventory and appraisal has been made in an effort to comply in all respects with the commission's Order 176, by listing the items of property owned by this company and stating their reproductive cost new less depreciation. The company reserves the right, in any appropriate proceedings involving the value of said property or any part thereof, to offer any other or additional evidence of value."

The consulting engineer of the Brunswick-Coburg (Australia) Tramways Trust has submitted his report on the construction of the line, the cost of which will be $673,052. It is anticipated that tenders for most of the work will be called for this year. A committee, consisting of members of the Melbourne City Council, the Trust, and the Brunswick and Coburg Councils, is considering the report.

H. H. Porter on Utility Earnings

According to H. Hobart Porter, of Sanderson & Porter, New York, the average earnings of public utility companies are holding up well under present disturbed financial conditions. In talking with a representative of the ELECTRIC RAILWAY JOURNAL, he spoke particularly of the affairs of the American Water Works & Electric Company, of which he is president, and also of other utilities in which he is interested.

Mr. Porter said that while the rate of increase in the gross revenues of the operating properties controlled by the American Water Works & Electric Company is smaller than in previous years, it is still good. Since May 1 the rate of increase over the corresponding period of 1913 has been nearly 50 per cent better than the similar increase of 1913 over 1912. The company includes many properties furnishing different classes of utility service. Some of these, on account of special influences arising from the disturbance of industry as a result of the war, show actual decreases in business. General observations seem to indicate that the slackening of industry affects transportation companies very early. Steam properties, which are so largely dependent upon freight for their great volume of revenue, are affected first. Electric transportation, furnishing the local service in cities and short-haul service between communities, is affected to a lesser degree. Electric central stations are affected to a still smaller degree except where a large amount of the consumption is required in manufacturing industries that are closed down. The receipts of water companies have a tendency in times like the present to show only a decreased rate of growth rather than an actual falling off in business.

One development of the situation which Mr. Porter mentioned with pleasure was the fact that in most cases municipal and other public authorities have co-operated in every way in helping the properties to make the best of the conditions imposed upon them by the war, such as the postponement of construction outlays which the present financial conditions make imperative. Public utilities, Mr. Porter said, are not affected so much directly by the war, as they are indirectly through the prevention of the sale of securities to provide funds for capital requirements. There is also an indirect effect arising from the demoralization of the market for cotton and the reduced consumption of iron and steel products. In some sections of the Northwest and the great Central Western States, however, the agricultural communities generally are exceedingly prosperous, wheat selling for more than twice its cost of production.

Mr. Porter added that the present crisis seems to have demonstrated some of the principal advantages of holding company ownership of public utilities as compared to independent ownership. An investor in the securities of a holding company has the added protection arising from diversity in the ownership of operating plants. The frequent result of this condition is that the decline in earnings of a plant in one locality is overcome by increased earnings in other plants. With properties situated in different localities and carrying on different classes of business, a large reduction in the total operating revenue seems to be less likely to take place. Moreover, companies have found it possible to secure capital for urgently needed improvements for controlled properties at times when independently owned utilities have not been able to do so.

One of the most important pieces of new construction work which Sanderson & Porter are carrying on at present is the hydroelectric development at Cohoes, N. Y., for the Cohoes Company. None of the public utilities in which they are interested is undertaking any construction work, except such as is absolutely necessary or was under way and almost completed.

When Mr. Porter was asked his opinion as to the duration of present conditions, he said that if the expectation of the best European observers for a long war was borne out by events, present conditions would have to continue or possibly grow worse. If, however, their prediction of a comparatively long war should not be accurate, this would have an immediate and overwhelming influence over all other considerations. In any event, the increased cost of capital must be marked for some time, and this must have a very radical effect on the future course of public utility financing. All over this country rate-regulating public bodies have made decisions on the assumption that capital could be had at rates substantially less than those experienced in the initial promotion of utilities. If utilities are to continue to grow under prevailing conditions, however, a much more liberal attitude must be taken by public authorities in reference to rates of return on capital.

Report of Latin-American Trade Committee

That industries of the United States will be seriously injured by loss of Latin-American trade if the restriction of commercial credits is not remedied, is one of the conclusions of the Latin-American Trade Committee recently appointed by Secretary of Commerce W. C. Redfield. The committee is headed by James A. Farrell, chairman of the National Foreign Trade Council, and consists of representatives of manufacturing, commercial, transportation and financial elements engaged in, or affected by, foreign trade.

The committee finds that the sister republics are turning to the United States for funds to carry on industrial development and that the greatest opportunity lies in systematic preparation for extension of trade when peace restores normal conditions rather than in hasty invasion of southern markets. Dependence upon London banking is sapping American foreign selling power. While the committee admits that trade with South America must partly depend upon London exchange as long as the republics owe heavily to Europe, it urges that in the mutual interests of all the American republics new credit machinery be created to escape this dependence as much as possible. The committee considered the proposed establishment of a "co-operative exchange" or merchant's clearing house for Latin-American trade. On account of the difficulty of obtaining co-operation, the necessity and difficulty of standardizing credits, the seasonal variations of shipments of South American produce and the expense, the plan was pronounced impracticable.

The committee believes that the present disorganization of the trade of the United States with Latin America may best be remedied and placed on a permanently satisfactory basis under the following plan:

(1) By the establishment of a dollar exchange, by the ultimate creation of a discount market, and, pending the establishment of a discount market, by the extension of adequate accommodation by banking institutions and the establishment of reciprocal balances in the United States and in Latin America for financing Latin-American trade; and (2) by the perfection of American selling machinery through furnishing additional support to commission houses familiar with Latin-American business; by forming associations of merchants and manufacturers to be jointly represented in Latin America, and by obtaining information as to the possibilities of developing retail stores in large Latin-American cities.

The committee believes that this country is hardly in a position to undertake considerable investments in South America at the present time, but industries with an already considerable trade at stake may well consider the necessity of protecting that trade by obtaining for their customers some relief from the present stringency. Such investments, if judiciously made, would yield an ultimate fair return and meanwhile provide a market for American materials which cannot now be sold.

Panic Economies Discussed

At the monthly meeting of the New York section of the American Society of Mechanical Engineers held on Tuesday, Oct. 20, the topic of the evening was "Panic Economies." A paper dealing with that subject was presented by Frederick A. Waldron, who stated that the causes of panics were, in general, suspension of credit, the calling of loans on high-grade collateral thus affecting commercial paper, and curtailing employment in many industries. Lack of work, in consequence, involved many non-producers who drew upon the banks to tide themselves over the depression, and this made the banks increase their cash holdings, producing further limitations in the ability to obtain credit.

Mr. Waldron pointed out the necessity for manufacturing firms to place themselves in a sound condition financially at the beginning of a panic by increasing their cash resources. He outlined the need for care in reducing running expenses, especially with regard to reductions in working forces, and advised the elimination of all non-productive work, experimental operations and the like. All doubtful stock should be turned into cash and unfinished material completed and sold. Necessary construction and engineering work might be carried on to advantage by co-operation with the engineering forces of other companies. In conclusion, the lessons to be learned from the present industrial depression were that the nations of the world were becoming interdependent, that our factories were not prepared to meet the demands of new markets and that the attitude of unwillingness to change standards must be abandoned if the trade of countries such as South America was to be obtained.

In the discussion which followed, William Kent referred to the panic of 1872 which came after the period of extraordinary expansion after the civil war and which was brought about by a single failure, the day rate for labor dropping from $1.75 to 87 cents in a few months. This panic lasted for several years, but in 1879 people suddenly awoke to the fact that the panic was over, and expansion began again. The reaction was almost as sudden as the advent of the panic, and the speaker felt that the recovery from the present depression was going to be just as rapid and just as unexpected. Every panic had been followed by a boom because things wore out and had to be replaced. Mr. Kent advocated a freer issue of emergency currency, citing the carrying on of the country's business throughout the civil war through the large issues of greenbacks. He objected to the maintenance of cash reserves in emergency times, stating that the reserves were intended to be used during panics. He advocated loaning money at high interest rates on commodities such as copper or cotton, so that the people could spend money and get things going again. He suggested that if everyone would pay his debts instead of hoarding money, panics would be reduced in severity.

During the discussion the point was raised that one great difficulty opposed to our obtaining the South American markets was that our efforts have always been along lines of labor-saving devices while in South America labor is very cheap. The United States, therefore, would have to revolutionize South America's methods before being able to sell machinery there.

COMMUNICATIONS

Broken Bolts in Built-Up Crossings

UNION TRACTION COMPANY OF INDIANA

ANDERSON, IND., Oct. 17, 1914.

To the Editors:

Your editorial of Sept. 12 concerning "Broken Bolts in Built-Up Crossings" calls attention to a problem of especial interest to electric interurban railways. Bolts and joints come loose when any locking device is used, probably from two causes. The first and by far the greater cause is the fact that the joint bars when placed are not driven in position as firmly as is possible, or the bearing at all points is not uniform. In this condition the vibration and natural deflection of the track, due to the operation of trains, will cause sufficient working to allow the joint bar to assume a different position. This will allow the bolt to become loose or, in other words, will require a shorter bolt length, and as a result the nut will be loose and require a second tightening. The second cause is that if a nut is of sufficient strength it can be tightened so as to make the bolt stretch. If the bolt does actually stretch a permanent set is obtained in the steel of the bolt. This means that the elastic limit of the steel has been exceeded and a new bolt should be installed.

If a bolt becomes loose from either of the above causes, a locking device which will continue to hold the nut tight on the bolt, even though the bolt is loose in the joint, is most desirable. With this type of lock the nut cannot work off under the vibration of trains and it may be retightened, and, in the meantime, will hold the joint bar in place. Of course all nuts have to be tightened occasionally on account of the wear in the joint. On the other hand, many locking devices, when the bolts loosen from the causes already mentioned, free the nut, and it gradually works off the bolt. Soon after the bolt will come out of the joint, on account of the vibration, and other bolts soon follow, with a possible dangerous condition resulting.

LOUIS A. MITCHELL,
Superintendent of Roadway.

Indexing Technical Information

NEW YORK, Oct. 15, 1914.

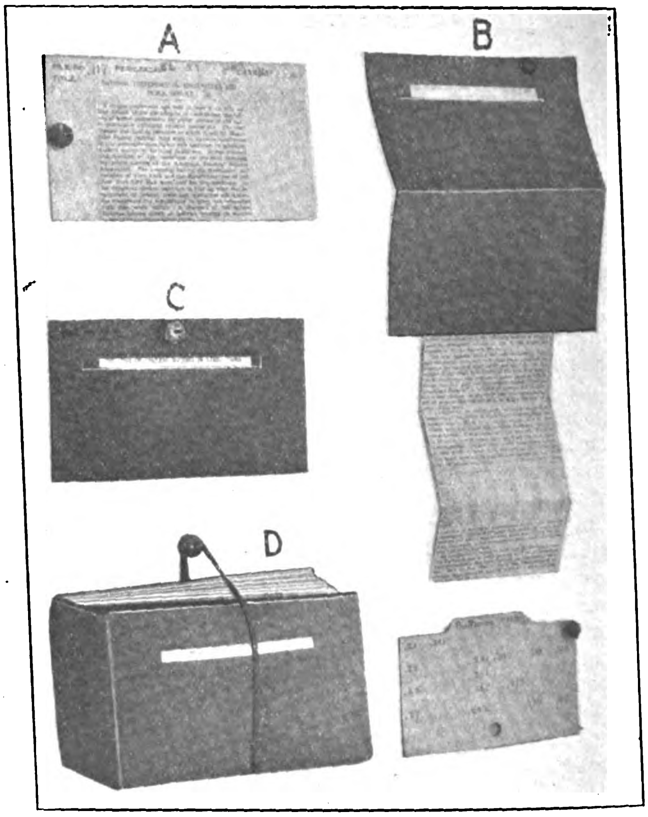
To the Editors:

The abstract of Mr. Alvord's article on "How to Use the Technical Journal" in your issue of Oct. 3 gives points of vital interest to every engineer, for the progress of any technical art is heralded in the technical press long before the facts are consolidated in stable form in text and reference books. I started some twenty years ago to index current literature pertaining to the electric transportation and lighting arts and tried faithfully every method which I knew—card indexing, scrap books, files, etc. When it came to getting working results from this material confusion arose. In carefully analyzing the causes of the difficulty it developed that an alphabetical index was a delusion and a snare. In the context of an article lies its value, and this context gives it a fixed place in any general scheme of technical knowledge as conceived in the mind of the indexr.

The most suitable index must be the creation of the user, but there are several underlying principles which, if understood, will smooth the way. In the first place, the whole subject to be indexed must be divided into suitable groups. For example, let us divide material on electric transportation under ten headings, taking them in the order of their natural occurrence in the growth of an electric railway property as follows, using the Dewey decimal system of numbering: .0, historical; .1, general description; .2, finance; .3, engineering; .4, operation; .5, power station; .6, transmission system; .7, equipment; .8, track, and .9, maintenance.

Under this rough classification we can commence to crudely sort out our information. Each individual compiling an index associates certain groups of facts together, and, if he will expand his index according to this preconceived correlation of facts it will not tax his memory to recall the proper location of desired data. The method of expansion by the Dewey decimal system permits subheadings to be interpolated *ad libitum* between consecutive decimal numbers and the growth of the index does not disturb the original decimal classification.

Another general principle which I have found useful in gathering data under groups, is that the physical location of the general data should be considered and the information should be filed in the class of physical material with which it is naturally associated. For instance, signal systems would go under track; copper wire tables under transmission, etc. This cuts down the number of cross-references required.



INDEXING TECHNICAL INFORMATION—EXHIBIT OF SAMPLE FILING DEVICES

Under the head of general descriptions of systems of electric transportation falls a large portion of general technical information, and the matter contained may fall also under any or all other general divisions of our index. In order to systematize this disorder I discovered that nine out of ten men will remember the geographical location of the event, structure or system to be inquired into and from this psychological peculiarity I found it desirable to arrange general descriptive matter geographically, giving consecutive numbers to all towns in order of an alphabetical state list of population of five thousand and over. As a short cut to this where electric railway topics are to be classified one can use the "Electric Railway Directory," in which every railway system in this country and Canada has been assigned a number. In my index each town has a card of its own and if any information appears regarding a railway system centering in a town, the index number of the data is entered on the card and under headings such as "transportation system," "power station," "equipment," etc. The clippings are filed in geographical order under the index number for the class, which gives the most useful arrangement.

So much for general system of indexing. Next comes the getting of this matter collated and indexed. Without going into all the features of the different methods I shall explain one that I have been using for the past sixteen years. I have more than 40,000 clippings sorted so that they are useful, and the railway index has expanded into more than 980 divisions. To save the regret of having destroyed what may be wanted later I clip everything, although many topics which afterward become important at the time of filing seem valueless. Two copies of every periodical clipped are required. The accompanying illustration shows the methods used in filing: *A* is a standard library card 3½ in. x 6 in. All cuttings not longer than 6 in. are pasted on cards of this size, and by turning the clippings over the lower edges and pasting them on the backs, both sides of the cards can be used. The title is pasted high enough to be used for the title of the clipping. Where an article is longer than 6 in. the folder is used, as shown at *B* and *C*. A slit is cut across the folder long enough to allow the clipping to protrude through and show the title. The clipping is pasted to the folder and folded up so as to be contained within it. Rubber stamps for the different journals clipped and the dates are used to reduce clerical work, which can be done by an office boy in his spare time. All that is required of the maker of the index is that he fill in the index numbers. With a little instruction any intelligent assistant can sort clippings into general classes, when they can be indexed rapidly.

The folder *D* contains all of the cuttings from the ELECTRIC RAILWAY JOURNAL for May 23, 1914. The small card used for geographical locations is shown in the lower right-hand corner. I use different colors of folders and cards for different years so as to give a chronological idea of the date of the information.

ALBERT B. HERRICK, Consulting Engineer.

A Good Word for the Card Index

PUBLIC SERVICE CORPORATION OF NEW JERSEY
NEWARK, N. J., Oct. 15, 1914.

To the Editors:

From the special librarian's point of view, the preservation of technical information in an accessible form is of the highest importance. But even with every facility at hand, it is a difficult problem to get the most out of a collection. For the average person, the cost of binding volumes of a journal, and the space required for keeping a file of any length prohibit this method of handling magazines; while the fact that few journals publish cumulative indexes covering a longer period than six months or a year would seem a very real barrier to the use of the index brought out with each volume. In addition, material published while the volume is still running, is unrecorded unless noted in some manner at the time of reading. A personal index, therefore, is necessary, both to keep a cumulative record of information, and to cover very recent publications.

To do away with indexing each article as read, and with cumbersome bound volumes, the vertical file may be resorted to, and separate articles arranged according to some definite plan. To do this without a card index, however simple, as Mr. Alvord advocates in his recent paper, is almost an impossibility. In the first place, if alphabetical arrangement under subjects is employed, we find that few articles have an unmistakable heading. Many might as readily be filed under several different heads, and unless a close watch is kept, there is always the possibility of filing similar material under slightly different topics. Thus in referring to an article, one can never be sure just what phase of the subject presented itself most prominently at the time of filing, nor that all the material on a given subject has been withdrawn for reference. In this connection, it would seem that a card index is an indispensable adjunct to the office file, for cross-reference purposes, at least, and to secure a uniform, easily consulted record of subject headings used. For instance, it is desirable to know at a glance whether abstracts or articles are filed under street railways, electric railways, transportation, interurbans, or any one of numerous titles more or less synonymous for this class of information. A simple cross-reference card, referring from each of these headings to the one preferred will settle at once where in the file all of the material on that topic will be found.

A question on which Mr. Alvord has not touched, but which must be met, is that of arrangement alphabetically by subject or according to a decimal or other classification. The former is simpler but usually separates allied, but slightly different, subjects. A decimal classification, such as "An Extension of the Dewey Classification Applied to the Engineering Industries," by L. P. Breckenridge,* while requiring some little care in application, brings all related information together, and permits indefinite expansion. Here again, a card index is needed to indicate the class number of article or abstract.

Whatever method of filing is used, however, one is lead to the same conclusion—that the readiest means of recording the location of data with the minimum of effort and the greatest accuracy is by some form of card index.

H. I. BREWER, Librarian.

A Standardization Committee Suggested for Car Design

BROOKLYN, N. Y., Oct. 20, 1914.

To the Editors:

With the advent of steel in passenger car construction, the question of standardization in design has become a pertinent one, and the railways as well as carbuilders' engineers keenly feel the need for adopting standards that will simplify construction and reduce to a minimum the labor attached to the preparation of plans, templates, dies, patterns, specifications, etc., in connection with placing of orders for new equipment.

You have suggested recently that the contour of roof, curvature of buffer, spacing of posts, construction of underframe and other similar details are subject to standardization to an extent that the expense of engineering in connection with purchases of new cars would be reduced. While some of the items mentioned could undoubtedly be standardized it will be quite evident to the designer that the mere adoption of certain standard dimensions in the general design would not result in lessening the cost of engineering nor reduce the preliminary shop work in connection with the construction to any marked degree. The variation in general dimensions and contour of the car structure, would hardly be considered a factor in the preliminary cost to the carbuilder, and to the railway engineer standards of the nature referred to might prove a hindrance rather than a help, in designing the best car for a given service.

I am firmly of the opinion that the opportunity for real standardization work in connection with car construction lies, not in the attempt to provide a standard car, but in adopting standard practices in connection with the details of design. The adoption of standard sections for framing members, pressings and drawn steel, riveting, moldings and framing connections together with uniform practice in connection with calculation of stresses, specifications and forms of contract should be of mutual benefit to the railways and carbuilders.

---

*Bulletin 9 of the University of Illinois Engineering Experiment Station.

A great deal could be accomplished along these lines by the organization of a standing committee of experienced designing engineers representing both the car builders and railways. This arrangement would afford a means for full and thorough investigation and consideration of the various items entering into car construction applicable to standardization and should result in reducing to a minimum the inconsistent variations in designs due largely to the individual ideas of the designers. W. E. JOHNSON.

Development of Carload Freight on Electric Lines

DETROIT UNITED LINES

DETROIT, MICH., Oct. 20, 1914.

To the Editors:

During the last few years a great deal of attention has been given to the development of the freight business on electric lines. Not the least interesting feature of this development is the method employed, which appears to vary greatly in different localities and which to some extent may be said to reflect the local conditions. Unfortunately, the freight business, on many of the electric lines, is confined almost entirely to that of moving less than carload quantities. This is so not because the carload business is undesirable but largely because the franchise restrictions and the terminal facilities available in the cities do not permit of the development of so-called carload business on even a moderate scale. However, even under such circumstances it may be possible to secure a small portion of the more desirable carload traffic.

Considerable discussion has been had as to the necessity for meeting steam road rates in competition for this freight business. Some electric lines have adopted the steam road basis of rates throughout, even to the low commodity rates, applying on carload business. The wisdom of such a course is questionable, as the cases where it is necessary to meet the steam road rate in order to secure a fair proportion of the business are exceptions. On the other hand, the steam road rates are so low, in many instances, that it is doubtful if an electric line operating freight cars in single units or with from one to four car trains could live under such rates.

Between growing communities there is always an exchange of commodities in carload quantities on which prompt service is required, and it is this class of business which should appeal to electric lines since it affords an opportunity of securing business at rates which may be made remunerative. There may be several things to incline the shippers to consider the electric lines, such as a shortage of cars and the indifference of steam roads, but service is the strongest argument, and once the business is secured, satisfaction in this respect will invariably overcome any objection to the higher rate.

The electric lines are here to stay. They are a force for much good in the development of the territory through which they pass, and the freight department is contributing its quota. The service afforded over these electric lines should be an important factor in determining a basis of freight rates. As a matter of fact, isn't freight service on electric lines really express service, minus the pickup and delivery features, just as dependable in every respect and in many cases more so? This is something which it is believed the public is rapidly coming to understand and appreciate, and in the end it is bound to redound to the good of the electric lines. N. RUMNEY,

Traveling Freight and Express Agent.

New Committees of the American Association

Several committees were authorized at the last meeting of the executive committee of the American Electric Railway Association held in Atlantic City, and in the case of two of these committees the members have been appointed by President Allen.

One of these committees is that appointed to take charge of the midyear meeting of the association, which is to be held this year during the last week in January in Washington, D. C. The committee in charge of this meeting is Charles L. Henry, chairman, M. C. Brush and J. H. Hanna.

Another committee has been appointed to consider the present rules of the association in regard to individual members, and this committee will report to the executive committee whether in its opinion any changes in these rules are advisable. The members of this committee are L. S. Storrs, chairman, Charles L. Henry, C. S. Mitchell, L. P. Crecelius and James H. McGraw.

The association will also have a committee on valuations. The personnel of this committee has not yet been selected by President Allen, but it has been decided that the committee will be made up of six members consisting of three executive officers of member companies, two consulting engineers and one accountant.

Engineers Disapprove of Registration

The Pennsylvania Legislature last winter authorized the appointment of a commission, which was duly appointed, to look into the advisability of the registration of engineers. Hearings were held in Pittsburgh on Oct. 15 and 16, and in Philadelphia on Oct. 19. A final hearing is to be held in Harrisburg Oct. 28. The commission prepared a bill, based on that drawn up by members of five national engineering societies, for the purpose of stimulating discussion and obtaining the views of engineers of the State.

At the hearings in Pittsburgh and in Philadelphia the general sentiment was strongly opposed not only to the bill offered but to any licensing bill. Previous to the Philadelphia hearing the Philadelphia Association of Members of the American Society of Civil Engineers discussed the matter and was represented before the commission by a committee, which presented a report giving arguments against any form of registration or licensing. The association, however, suggested some measures which would help to accomplish the primary object sought, that is, the safeguarding of life, health and property. In the committee's opinion this could more certainly be accomplished by requiring State approval of plans for engineering structures than by attempting to weed out by examination incompetent engineers. The commission expects to present a preliminary report to the Governor about Nov. 1, and a final report at the end of this year.

A consular report from Japan states that there are now within a radius of 50 miles of Osaka close on 250 miles of double track in operation and 80 miles more under construction or proposed in the near future. The growth of light railways has been slower, there being at present less than 50 miles, but another 50 miles are under construction. Numerous plans are projected, but hitherto these have been held up by the difficulty of finding capital.

Equipment and Its Maintenance

Short Descriptions of Labor, Mechanical and Electrical Practices in Every Department of Electric Railroading

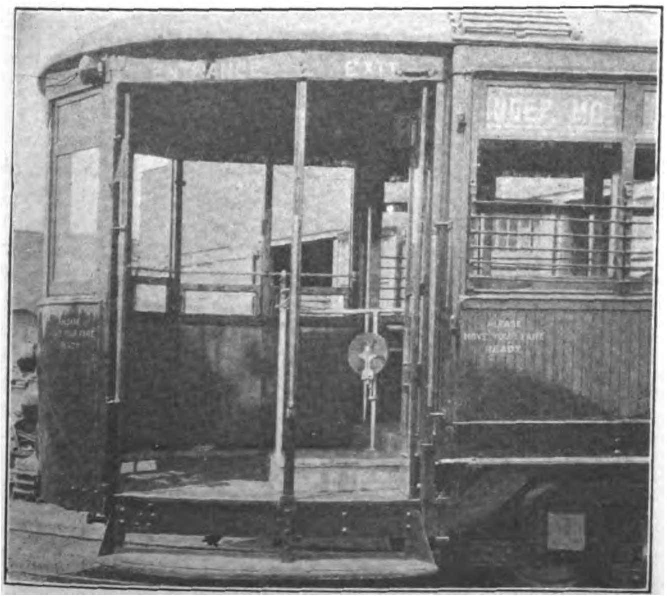
(Contributions from the Men in the Field Are Solicited and Will be Paid for at Special Rates.)

Standard-Wheel Low-Step Car with Opera Seats

BY G. T. SMITH, MASTER MECHANIC METROPOLITAN STREET RAILWAY, KANSAS CITY, KANSAS CITY, MO.

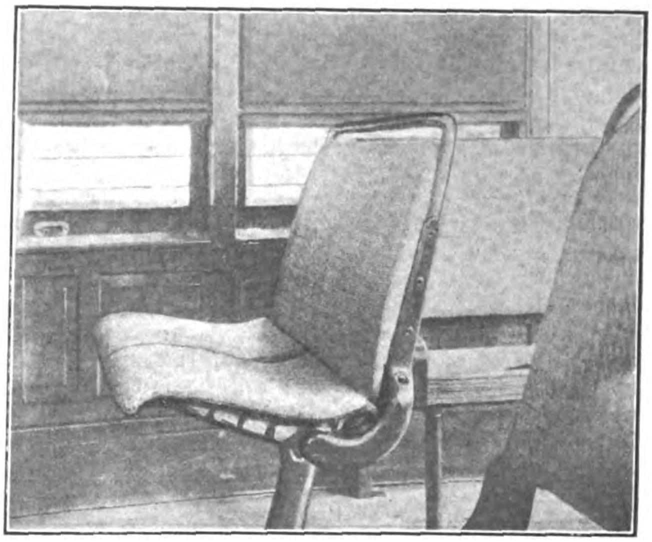
A single-end car containing such refinements as a 13½-in. step with 34-in. wheels and opera-chair seats has been put in service recently by the Metropolitan Street Railway, Kansas City, Mo. This equipment was developed in the company's shops from an old car remodeled for experimental purposes. The method of obtaining a low step without reducing the wheel diameter should be of particular interest. The step height from the rail is 13½ in., from the step to platform floor 12½ in. and from the platform floor to the car floor 9 in., making a total height of 35 in. The difference between this 35 in. and the necessary wheel clearances was made up by the combined ramps or incline on the rear platform and car floor. The car floor proper was ramped or inclined 2½ in. from the end sill to the body bolster. The platform floor was ramped 3 in. in the form of a spiral, starting from a point 14 in. inside the entrance door and extending to the end sill of the car.

In order to avoid placing the conductor on the inclined floor, a small platform or dais 4½ in. high was built in the center of the vestibule beside the step at the bulkhead. This dais is also used as an auxiliary step at the rear exit door. In service, the dais is found to be advantageous, since it elevates the conductor above the passengers' heads and gives him the desired commanding view, as from 75 to 80 per cent of passenger leave the car by the front exit. One of the accompanying illustrations of the rear platform indicates that the spiral ramp is inconspicuous. It will also be noted that the conductor's stand is fitted with an adjustable seat which folds automatically when not in use.

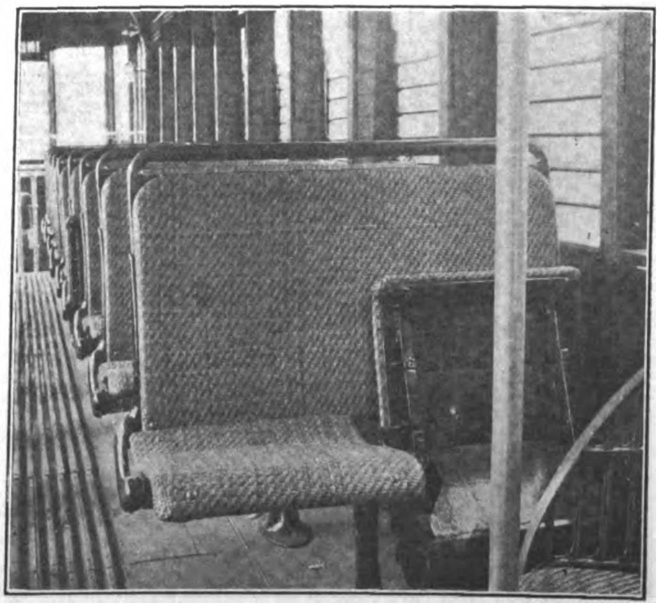


KANSAS CITY CAR—REAR PLATFORM WITH CONDUCTOR'S DAIS AND INCONSPICUOUS SPIRAL RAMP

Both the rear exit and entrance doors were hinged and all operating mechanism was placed underneath the platform. The doors are controlled through two operating handles, one above the other, installed at the dividing rail between entrance and exit aisles. The front exit door is of the sliding type and is operated in conjunction with the folding step, the mechanism being arranged so that the step is completely lowered when the door is one-third of the way open. This detail was arranged to prevent a passenger in a hurry from passing out of the door before the step was in position for regular service.



KANSAS CITY CAR—SIDE VIEW OF OPERA SEAT IN LOWERED POSITION



KANSAS CITY CAR—OPERA SEAT SHOWN IN FOLDED POSITION

Undoubtedly the seats constitute the most novel feature in the design of this car. These are built like opera chairs, there being two hinged seats to one back. The seats are covered with rattan and no springs are used in the upholstering. They are very comfortable and much superior to the upholstered type from a sanitary standpoint. Another feature is that when the car is crowded and the person nearest the wall of car desires to leave, it is unnecessary for the other seated passenger to step out in the aisle because the outside passenger simply rises and folds his seat behind him, thus making sufficient space for the passenger nearest the wall to pass by him.

Still another feature of these seats is that they facilitate car cleaning. During the cleaning the seats may be folded against the back, thus giving the sweepers and cleaners free access to the floor. As shown in one of the accompanying illustrations, the seats are supported with one pedestal placed at the center, the overhang on the aisle being free from the floor to the bottom of seat. The inside end of the seat is attached to the car side by a bracket, which makes a very rigid construction. The electric heaters are of the short cross-seat type, and are placed beneath the seat adjacent to the wall, the seat castings having suitable lugs cast thereon for the attachment of the heaters.

Car illumination is supplied by five 54-watt tungsten lamps with Holophane shades installed along the center line of the body. In view of the difficulties encountered in the drilling of the steel carlines in the roof of an old car, the six-lamp circuit with selector switch was not used. In order to provide some light, should the main lighting circuit fail by the burning out of a lamp, an extra or sixth lamp was installed in the circuit used for the signs and headlights which are supplied with 23-watt tungsten lamps. By the use of a three-way switch a light from the front sign can be diverted to the inside circuit. This, with two 23-watt lamps of the same circuit which light the rear platform, gives sufficient light until the car reaches a terminal.

Ground Connections for Clusters

BY G. H. MCKELWAY, DISTRIBUTION ENGINEER BROOKLYN RAPID TRANSIT SYSTEM

On roads using wooden trolley poles, whenever it is desired to hang a light cluster to light a station platform or road intersection, it is the custom to run the ground wire down the pole, stapling it to the pole to make a neat looking job and also to prevent or at least discourage the theft of the wire. Then the wire is run underground from the foot of the pole to the nearest track rail, to which it is attached by means of a bond terminal.

But on lines where the overhead work is supported from metal poles it is common to use the pole itself as part of the negative return. Instead of carrying the ground wire down the pole it is customary to connect it to the pole at the height of the cluster bracket or span wire and let the pole carry the current to the ground. Then the pole itself is either considered to be well enough grounded to make unnecessary any connection to the rail, or, if that is not thought to be desirable, a wire is run underground from the base of the pole to the track and grounded there. This latter precaution may seem unnecessary, but the practice of connecting to the rail as well as to the pole is standard with many companies and is rightly considered to be safer and sometimes more economical. The only advantage that the first plan has over the second is the matter of first cost, and generally of maintenance as well.

The greater cost of the second method is not so much the cost of the extra piece of wire as of the labor to open the street and install it. The cost of this opening is generally high because metal poles are seldom used except in cities where the streets are usually paved, and the cost of opening up an asphalt or stone or wood-block pavement laid on a concrete foundation is appreciable and is often increased by the necessity of having to pay an excessive sum to the city inspector who is assigned to see that the opening and repairs are properly made. However, there are three objections to considering sufficient the grounding of the pole alone. Iron poles are nearly always set in concrete, and good concrete is a pretty fair insulator although the concrete placed around the butts of poles is often of a rather poor quality. The three objections are as follows:

Lamps—Full voltage does not get across the lamps owing to the poor ground and, therefore, they do not burn brightly.

Poles—The continual passage of current from the lamps to the pole and from it to the ground causes electrolysis, which gradually destroys the pole at the ground line. This objection may seem to be rather far-fetched, but the writer knows of several instances where such marked deterioration of the pole has occurred just at the ground line that it has been necessary to renew the poles because they were dangerous in their weakened condition. In one case where a common ground wire from several clusters was grounded to a pole, that pole soon failed and was replaced with another with the same ground connection. The result was that the second pole failed within two or three years. Then a ground connection was made to the track and the trouble ceased.

Persons and Animals—It is quite easy, in dry weather, even for the poor concrete in which a pole may be set to become a fair insulator, and sometimes a very good one, with the result that as soon as the cluster is lighted the pole becomes charged and is then a source of danger to any person or animal that might touch it.

A good connection to the nearest track rail does away entirely with the first and third objections and makes the second practically negligible, although with a soil of low resistance a very small proportion of the current may leak to the rail through the ground instead of being carried away by the wire. Please note, however, that the writer says "a good connection." As soon as the wire becomes broken or the terminals loosen from either the pole or the rail the connection drops into the first class and acquires all the objections of that class.

A still better plan, although more costly, is to run the ground wire directly from the cluster to the track, in the same general manner as when wood poles are used, instead of making any connection to the pole. It is of course impossible to staple the wire to an iron pole and, in a city, the necessity for neatness of construction and protection against the theft of the wire is even greater than where wood poles are permitted.

Therefore, the obvious way to install the wire is to run it down the pole in an iron or fiber pipe, the latter being attached to the pole by means of bands around both. The iron pipe is the stronger and is almost always used, although fiber has been substituted on some lines because of the belief that with iron pipe the ground wire would not help as a lightning arrester due to the choking effect of the iron pipe which surrounds it. This precaution seems to be unnecessary, but whatever construction is used the result is the best possible ground because there is a strong permanent connection direct from the cluster to the track.

The Engineer of London states that the percentage of unemployment in Great Britain during August, the first month of the war, was 6.3. At the end of September the percentage of unemployed had fallen to 5.1. These figures apply to the insured trades.

Catenary Experiences on the Empire United Railways, Inc.

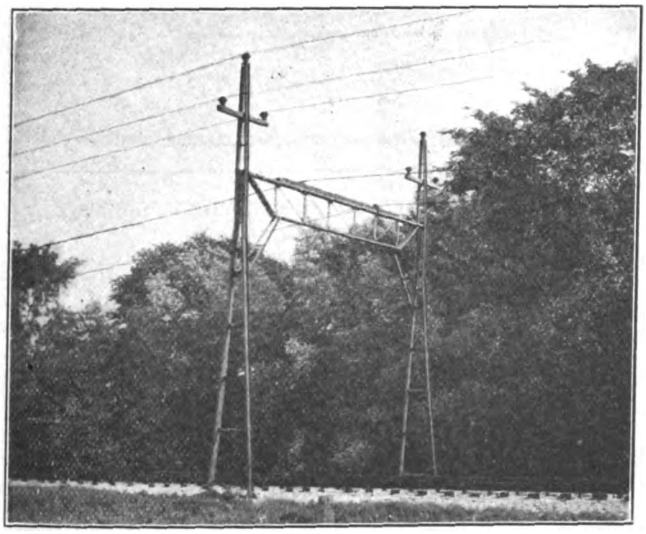
BY THOMAS H. MATHER, CHIEF ENGINEER

Catenary construction on the original Syracuse, Lake Shore & Northern Railroad and on the Rochester, Syracuse & Eastern Railroad (these roads being now merged under the name of the Empire United Railways, Inc.) has proved to be a decided improvement over the pole-span construction. On the initial installation from Long Branch to Baldwinsville, some mistakes were made owing to erroneous ideas regarding what the catenary would and would not do.

The construction consisted of Archbold-Brady steel bridges on four concrete pedestals, spaced 300 ft. apart. The messenger was 9/16-in. steel cable. Hangers were 10 ft. apart, excepting on six spans, where the spacing was 20 ft. apart. This difference in spacing was owing to the fact that the second track was extended some 900 ft. farther than originally intended, and as the overhead material was already purchased, a makeshift erection of half the number of rods on these last spans was employed. The only provision made against side sway was a steady strand from the hanger to the side of the bridge; that is, on tangents only once in 300 ft. Anchor bridges were erected at each end of this 7-mile section.

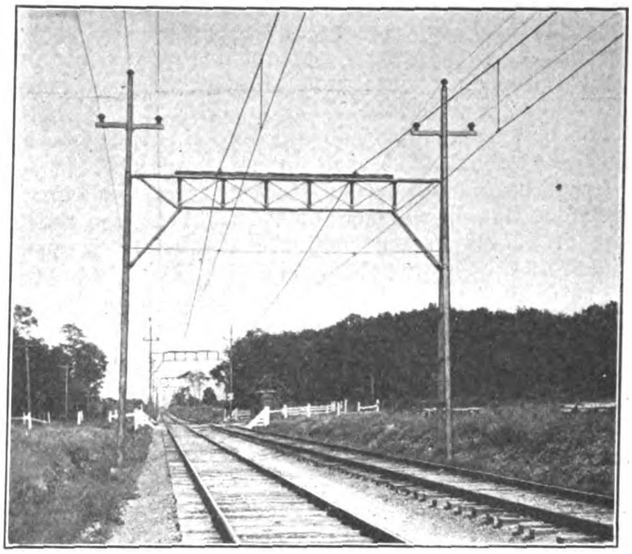
The doubts entertained were: first, that 10-ft. spacing of hanger rods was too infrequent; second, that the bridges were of too light construction; third, that during heavy storms, with wind blowing at or about right angles to the line, the sway of the trolley wire would be so excessive as to interfere with successful operation.

Operation was started before the construction of the overhead was completed, about 2 miles of the line being entirely loose, and not steadied at the towers. The first car went over the line on a day in February, with a gale of wind from the west (the line is approximately north and south). No sway that interfered with operation was observed. On the 10-ft. spacing there was excessive "chattering," which materially decreased on the 20-ft. spacing and every bridge stood and is standing yet.



CATENARY CONSTRUCTION EMPIRE UNITED RAILWAYS, SHOWING CONSTRUCTION OF TOWERS

Acting on the practical lessons received, every alternate hanger was removed. Later 30-ft. spacing was used, then 50-ft., and later still 60-ft. spacing. This last spacing has proved entirely satisfactory. On this first section, an attempt was made to provide for expansion by leaving a camber of about 12 in. in the trolley wire in the center of the span, so that in warm weather the expansion of the messenger would make the trolley wire straight from tower to tower. The results were not as expected and attempts at such adjustments were not repeated on later construction. It has been found that during the first year after construction both messenger and trolley wire require adjustment, owing to changes of temperature, and thereafter give little trouble.



STANDARD CATENARY BRIDGE CONSTRUCTION ON THE EMPIRE UNITED RAILWAYS

The cost of this initial section was about $4,580 per mile of double track, including all material, bridges, concrete foundations and all erection, but exclusive of the cost of copper wire. This exceeded the cost of pole-span construction by about $1,200 per mile. This pole-span construction was with poles 35 ft. long, tops 8 in. diameter and butts not less than 14-in. diameter, set about 85 ft. apart, and the cost was $3,279 per mile of double track.

On later construction from Baldwinsville to Fulton some changes were made, such as building a more economical bridge and removal of hanger rods, which effected a slight economy; but on the latest construction, a still further and more decided economy was obtained by using as messengers the two 500,000 circ.-mil feeder cables, which had been carried on cross-arms on the towers. This saved the cost of the steel cable messengers and the cost of erection of the feeders, and reduced the cost of material (excepting copper) and erection complete to $3,517 per mile, or $238 more per mile of double track than pole construction.

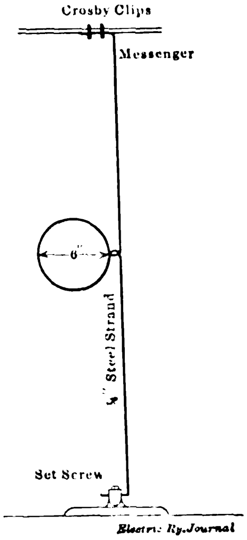
The appearance of a railroad with this catenary is greatly improved over that with poles, and insures greater safety in operation of high-speed roads at grade highway crossings, as the open nature of catenary does not obstruct the motorman's view on each side, as do poles.

Maintenance costs are somewhat lower than on pole lines, but as the principal cost is the renewal of rods and sister hooks, a hanger device with screw connections eliminated would materially reduce the cost of maintenance. The corrosion of the threads in the rod and sister-hook connection makes renewals necessary in from two to four years. A flexible hanger is recommended, rather than a rigid type, especially on single track, where the impact of the trolley wheel is on both sides of the ear. The tendency in these cases is to bend the trolley wire upward, leaving the ear slightly under the wire and offering an obstruction to smooth travel of the trolley wheel.

An experimental home-made hanger of ¼-in. steel strand has been in use on the Rochester-Syracuse division for about four months and so far has given satisfaction. In its first form a loop was put in the strand about half way between the trolley wire and the messenger, and twisted to a horizontal position. While this gives flexibility under compression yet it has slight resistance to tension. In the later form an additional twist is given leaving the loop vertical and giving greater resistance to any tensile stress without impairing its flexibility. The strand is attached to the messenger by two Crosby clips and to the ear by bending about 2 in. of the strand at right angles and introducing it into a horizontal hole through the boss. It is fastened by a set screw at the top.

The bridges require painting once in five years and the cost is about $2.35 each for paint and labor.

It will be found more satisfactory to build a separate telephone line on the edge of the right-of-way, and the cost of catenary construction hereinbefore given includes this. The telephone line is of 25-ft. poles 6-in. diameter at tops, set forty per mile, with two circuits of No. 10 hard-drawn copper wire.



HOME-MADE HANGER

Hard spots have not developed on any part of the trolley wire, but on single track, portions contiguous to the ears have become slightly annealed.

There is an assertion by linemen and car men that operation on catenary is not so much impeded by sleet as on pole lines. There is no good proof that the catenary line will stand up under more sleet than poles will, and it is possible that sleet may more readily shake loose on the longer spans of catenary. Trolley sleeves of the Ohio Brass Company's Type A or Type C are recommended, as trouble has been experienced with any type surrounding the wire, especially if they are located near the hanger rods.

Pull-off poles on curves are spaced 100 ft. apart and a ¼-in. steel cable messenger is run the entire length of the curve attached to the towers and these poles. Pull-offs are attached to messengers and trolley wire and secured to this cable.

The catenary on this railway has shown a decided superiority over any pole-span construction in appearance, in its permanency and in its maintenance cost. As a large proportion of that cost is due to the type of hanger rod used, the installation of a flexible type secured to the messenger, in some other satisfactory method than by a device involving the use of a screw, will result in a further reduction. Since the difference in initial cost of construction is so insignificant, in a choice, a consideration of that feature would be negligible. While this particular type of catenary was erected as a pioneer effort, those responsible for its adoption feel that their decision has been justified by the results. On the road employing this type of catenary, no pantograph operation is used, all cars being equipped with trolley pole and wheel, and attaining a speed of 60 to 65 m.p.h.

The Georgia Railway & Power Company, Atlanta, Ga., has distributed twenty-three pulmotors intended for free use of the public in emergencies along its 600 miles of line in Georgia.

Wheel Gages Used at Decatur Shops

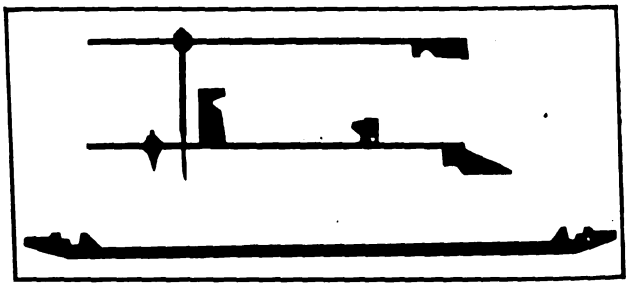
BY J. C. HOUGHTON, MECHANICAL DEPARTMENT ILLINOIS TRACTION SYSTEM

At the main shops of the Illinois Traction System at Decatur, Ill., we have built and used for some time with accurate results the wheel gages shown in the accompanying halftone. These gages are lettered *A*, *B* and *C*. They are designed for use with M.C.B. standard wheels. The material of which they are made consists of ⅝-in. cold-rolled steel and 3/16-in sheet steel. The scribers are ⅜-in. Stubbs steel.

In mounting a new wheel and axle, gage *A* is first used for finding the center of the axle. The heel of the gage is set up against the fillet of the journal and a mark is made at the approximate center, using the scriber. The same operation is then performed from the other end of the axle and another mark is made with the same setting, and then the proper adjustment is made to determine the center. The scriber is adjustable and can be used on various sizes and lengths of axles, and yet it is so securely mounted that very accurate work can be accomplished with it.

After the center of the axle has been determined as just described, gage *B* is used while the first wheel is being mounted. The heel of this gage is a contour of the M.C.B. steel wheel tread. The use of the gage is a very important step in mounting wheels. After the first wheel is in place, it is a very easy matter to determine the position of the second wheel by the use of the width gage *C*.

Our method of using gage *B* is as follows: Press the first wheel on a few inches. Then put the contour over the wheel and level up the bar with a level using the adjustable scriber which moves up and down in the hollow stem, according to the different sizes of wheels. After the bar is level and the scriber rests on the axle, it is locked in this position and the wheel is then pressed on until the scriber comes to the center line made by gage *A*. The scriber does not slide back and forth on the bar as it does on gage *A*. It must be secured after once set for the gage of track for which it is used. Gages *A* and *B* can be used for narrow-gage work.



ILLINOIS TRACTION SHOPS WHEEL GAGES

By the use of gage *C*, which is made of flat steel and cut out at the end in accordance with the M.C.B. requirements, it is easily possible to get an accurate setting for the second wheel.

It is reported in Australia that the war will not appreciably retard the carrying out of the Melbourne suburban railway electrification scheme; only some $30,000 of material is of German origin, and it can be obtained elsewhere. In connection with the Sydney railway station lighting and signaling projects, a portion of the work has already been carried out, but owing to the difficulties in obtaining supplies of apparatus from Europe, the completion of this work is uncertain.

Building a Way Station for $263

The following data cover the constructional features, bill of material and costs of a standard 8 ft. x 10 ft. way station as built by the Northern Ohio Traction & Light Company:

The platform consists of a cinder foundation upon which rest 6 in. of concrete, the upper 1 in. being a wearing surface. The body of the slab is 1:2:4 mixture, and the wearing surface one part cement and two parts sand. The platform is cut into sections, as shown on the plans, this cutting extending through to the foundation. The surface is finished rough.

As anchor bolts 5/8 in. x 12 in. machine bolts with washers are used. These are carefully placed, using a wooden template made to accord with the drawing.

The framing is entirely of dressed lumber. The wall framing, with the exception of the doorway and window openings, is completely covered with No. 27 gage "Trussit," fastened on with staples. The "Trussit" is then plastered, first on the outside, with a mixture of one part Portland cement and three parts sand, tempered with lime mortar, if necessary. This plastering is 3/8 in. thick outside of the metal and floated to an even surface. When the outside is set the inside is plastered in the same manner.

The rafters are curved, as shown on the drawing. On these is laid 1-in. x 6-in. match flooring, which in turn is covered with four-ply roofing felt to form a bedding for the tile. The tile is 7-in. x 10-in. vitrified red Spanish roofing tile, carefully laid. The door casing, window frames and outside corners are put on after the plastering is done and set.

Seats extend around three sides of the building, as shown on the drawing.

Two porcelain wire conduits are placed in each end of the building, as shown on the drawing, and a 1-in. hole is left in the floor, also as shown. All woodwork is painted. The outside is given first a priming coat, then two coats of dark red paint, dull finish, to harmonize in color with the roof tile. The inside is given a priming coat, then two coats of dark green paint. The underside of the roof is painted white.

LUMBER BILL

The following bill of lumber was furnished for an 8-ft. x 10-ft. station in 1913 by the Frederick Lumber Company for $55.

OTHER MATERIAL

Platform

4.17 cu. yd. 1:2:4 concrete
6 2/3 bbl. cement
1.9 cu. yd. sand
3¾ cu. yd. stone
0.83 cu. yd. 1:2 mortar
2.66 bbl. cement
0.75 cu. yd. sand
10, ⅝-in. x 12-in. machine bolts

Roof

2½ squares red Spanish roofing tile 7 in. x 10 in.
14 ft. cresting, Spanish roofing tile.
28 ft. eave tile, Spanish roofing tile.
2 pinials, Spanish roofing tile.

Walls

40 sheets, 15½ in. x 96 in., No. 27 gage "Trussit."
281.39 sq. ft. plastering, 1in. thick, 0.89 cu. yd.
2.1 bbl. cement.
0.89 cu. yd. sand.
1.5 sacks lime for tempering.

Wiring

2 porcelain conduits.

Painting

Done by contract.

COST OF ONE STATION

The cost of all items for the standard 8-ft. x 10-ft. way station totals as follows:

Lumber, complete with door, window frame and sashes	$ 55.00
"Trussit," 428 lb., at 4 cents (less discount)	16.84
Roofing tile (cost includes freight)	41.25
11.43 bbl. cement, at $1.28	14.65
3 54 cu. yd. sand, at $0.60 ton	2.58
3.75 cu. yd. stone, at $0.95 ton	4.75
1.5 sacks lime, at $0.50 sack	.75
Labor of erecting	115.07
Painting	12.00
Total cost of building	$262.89

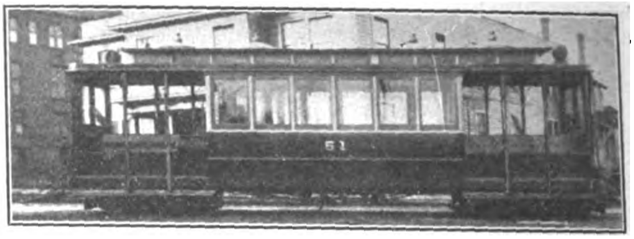
Oil as a Cause of Commutator Pitting

In a paper read before the Association of Iron & Steel Electrical Engineers B. G. Lamme stated that the phenomenon of pitting or the eating away of the mica between commutator bars had often been falsely credited to commutating conditions, to high voltage between bars, too thin mica, quality of carbon brush, use of lubricants, etc.

Some years ago an extended study of this matter had been made. This was based upon a large number of cases of actual trouble. The results from machines in actual service were so conflicting that no positive conclusions could be drawn. However, eventually the evidence pointed to oil as one of the fundamental conditions in this trouble. Extended tests were then made to determine the effects of oil on the mica, and the results indicated clearly that those insulations which absorb oil were liable to pit or eat away in time. Apparently where the oil could dissolve out the binding material in the mica, minute particles of carbon or copper would be disseminated through the mica, thus decreasing its resistance locally. Combustion of these particles would usually be noticed as "ring-fire" around the commutator. Ring-fire is almost always due to incandescent carbon particles scraped off the brushes, but is not usually harmful if the mica adjacent to the spark does not burn or deteriorate. Experience shows that the ordinary good grades of mica plate are not affected by such ring-fire, and it is only when foreign conducting particles penetrate into the plate that this burning may gradually eat away the mica. It was found that some binding materials used in building mica plate were more soluble in oil than others, and it was noted that in those plates with soluble binders the pitting was most pronounced. This led then to one solution of the pitting trouble, namely, the use of what might be designated as insoluble binders in the mica plate, with very tight construction of the commutator, so that oil could not penetrate along the sides of the plate, and with care in preventing oil from getting on the commutator.

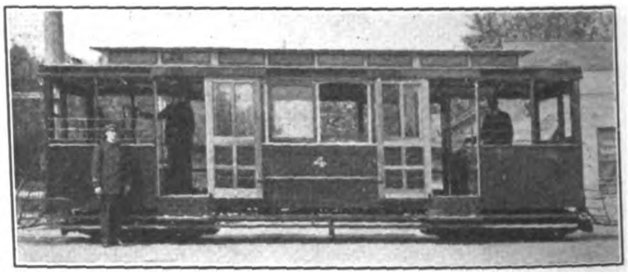
Seattle Open Cars Changed to Closed Prepayment Type

For many years past the standard cable car used on the Seattle division of the Puget Sound Traction, Light & Power Company has been of the California type, similar to car No. 61, as shown in the accompanying cut. This car, with its open ends and running board, has been the cause of an abnormal number of boarding and alighting accidents. This trouble is aggravated by the fact that the cable lines operate at an approximate speed of 10 m.p.h., which is a further invitation for persons to board or leave the car while in motion.



SEATTLE CABLE CAR BEFORE REBUILDING

In March, 1913, a trial car, redesigned so that the entrance and egress of passengers would be controlled by the gripman or conductor, was put in service and was operated with marked success. During the past year eleven additional cars have been converted into the inclosed type, as shown in the cut of car No. 4. It was originally estimated that, if 50 per cent of the step accidents on the cable lines could be eliminated, the interest on changing these cars from the old type to the inclosed type would be about 20 per cent. It has worked out in practice that approximately 75 per cent of the step accidents have been eliminated with the inclosed type of car. The interest on the investment made in converting these cars is therefore about 30 per cent.



SEATTLE CABLE CAR AFTER REBUILDING

A further saving from the operation of these cars is due to the fact that at the present time all passengers enter at one point, depositing their money in fare boxes.

The inclosed type of car weighs, without passengers, approximately 14,700 lb. This is practically the weight of the car before it was redesigned. The width is 8 ft. 8 in. over all. The car seats thirty passengers. These cars are equipped with Exide batteries, 5-watt 8-volt lamps, and have nine lights. The center portion is entirely inclosed, both ends being open with two sliding doors on each side. The step folds with the sliding door.

Dynamiting Concrete Track Foundation

For several years the United Railways Company of St. Louis, Mo., has resorted to dynamite as the most economical means of loosening the concrete foundations under its track when rehabilitation is necessary. The method adopted has been to blast with small charges of dynamite which were sufficient to shatter the concrete so that it could be taken out in large pieces, and at the same time not damage the surrounding property. Essentially the equipment used in this work consisted of a car equipped with motor-driven air compressor for use in driving the drills and a cover car to confine the blasts.

After holes have been drilled in the concrete, slightly below the center of gravity of the section to be removed, a 0.1-lb. charge of 40 per cent dynamite has been rammed into it. A fulminating cap has been used to explode this charge, twelve holes being shot at one time by an electric firing machine. In order to prevent damage by flying rocks or broken concrete at the time of the explosion, each blasting gang has been supplied with a cover car, which is merely a flat car with a heavy bottom and side boards extending below the car floor. This equipment has proved very effective in service and has not been superseded since it was adopted in 1906. Views of the cover car, the air compressor car and 1¼-in. drills, as well as the cover car during an explosion, are shown in the accompanying illustrations.

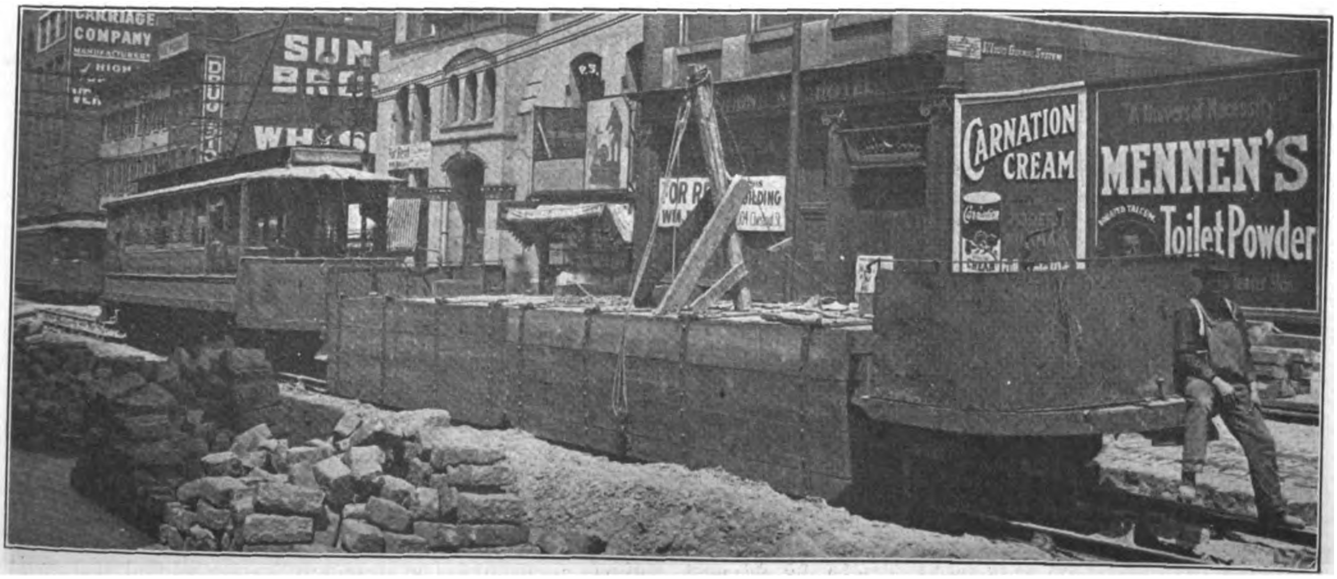
Ingenious Fusible Plug

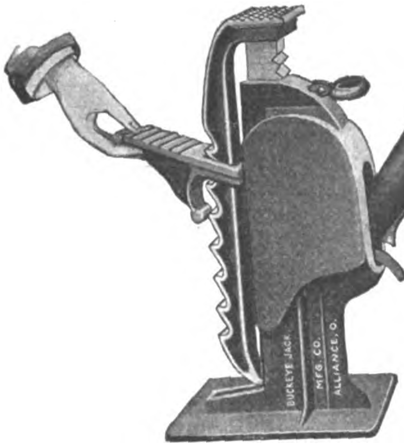
A correspondent of *Power* describes an ingenious fusible plug which is reported to have overcome the difficulties experienced with the usual type set directly in the boiler shell. The new form is set at the top of a piece of ½-in. pipe several feet long screwed through the shell and extending below the lowest normal water level of the boiler. The fusible plug is composed of an alloy that melts at the temperature of the steam, or, say, 350 deg., but, since the lower end of the pipe is below water level, no steam can reach the plug unless the water is low. Normally the radiation from the pipe cools the water that is in it considerably below steam temperature and keeps the plug from melting.



ST. LOUIS DYNAMITE CARS—VIEW OF COVER CAR USED TO CONFINE EFFECTS OF BLAST

Jack with Adjustable Auxiliary Foot

The Buckeye Jack Manufacturing Company, Alliance, Ohio, has recently added to its extensive series of jacks a design of 5-ton capacity designated the No. 14 Special. A feature of this jack, and one said to be original with its manufacturer, is the adjustable auxiliary foot. This adjustability is secured without the use of tools so that changes for operation at almost any height can be made very quickly. The height when the bar is down is 14¼ in., the raise is 7½ in., and the height when the bar is up is 20½ in. The jack is made of malleable iron. It weighs about 40 lb., and is made both single and double acting.



JACK WITH ADJUSTABLE FOOT

Safe Deposit Fare Box

For the past several years the Ohmer Fare Register Company, Dayton, Ohio, has been exploiting an unusual type of fare box known as Ohmer's "Safe Deposit." This box contains a steel tube, which, when removed, automatically seals the deposits placed therein.

FARE BOX APPLIED TO PAY-WITHIN PREPAYMENT CAR

The merits of this box may be summarized as follows: Its size economizes platform space; it permits tickets in strips to be deposited; it has no exposed screws or bolts; the cylindrical insert is easily handled and practically indestructible and the insert locks automatically when withdrawn from the box; the lower half of the box is made of steel and the upper part is cylindrical plate glass; ingeniously placed baffle plates make it difficult to extract coins from the box; the box can be placed anywhere on a platform without interfering with traffic and it can be maintained at slight expense.

The dimensions of the fare box are as follows: length of outside tube, 15⅞ in.; length of insert tube, 12¾ in.; length of glass, 10⅞ in.; outside diameter of tube, 5 in.; outside diameter of insert tube, 4¾ in., and length of fare box with hopper, 30¼ in. The weight with insert tube is approximately 20 lb.

Side-Entrance Trailers for Chattanooga

Growing appreciation of the merits of the side-entrance car for trailer service is shown again by the purchase of two such cars by the Chattanooga (Tenn.) Traction Company from The J. G. Brill Company. These cars, which seat fifty passengers on end and transverse rattan seats, are 38 ft. 3¾ in. over the vestibules, 30 ft. 2¾ in. over the car posts, 8 ft. 4 in. over the sills and 8 ft. 6⅞ in. over the base of the arch roof. The height from the top of the rail to the sills is 2 ft. 9½ in. The underframe of the car is composed of metal and the body of wood with interior finish of cherry and bronze trimmings. The body weighs 15,315 lb. and is mounted upon 53-D trucks with Carnegie steel wheels and high-test heat-treated steel. Miscellaneous fittings include eight Brill exhaust ventilators per car, Tomlinson couplers and Hedley anti-climbers. A 12-in. horizontal wheel brake is provided at the conductor's stand. The cars have swinging glass doors, folding steps, push-button system and International R-5 registers for fare recording.

News of Electric Railways

NEW HAVEN DISSOLUTION DECREE

A Summary Is Presented of the Terms Under Which the New Haven Railroad Will Divest Itself of Its Principal Subsidiaries

The decree embodying the agreement reached by the New York, New Haven & Hartford Railroad and the government for the settlement of the Sherman law dissolution suit begun by the United States against the company was signed on Oct. 17 by Judge Mayer in the Federal District Court at New York and was immediately filed. As a result of this settlement the New Haven Railroad is left in possession of all its railroad lines except the Boston & Maine and its traffic agreement with the Boston & Albany, but it has been compelled to divest itself of all its electric railways except the New York, Westchester & Boston Railway. As regards its steamship lines it loses all except the Sound liners and must abide by the decision of the Interstate Commerce Commission concerning these. Until that decision is handed down it cannot dispose of any of the vessels or real property of the companies concerned, and cannot discontinue operation of the steamship lines or change any existing routing or traffic arrangements. On the other hand, the government is prevented by the decree from again bringing action against the New Haven Railroad upon any of the issues presented in the suit.

In order to accomplish the separation of the New York, New Haven & Hartford Railroad and the Boston & Maine Railroad and of the New York, New Haven & Hartford Railroad and the electric railway and steamship companies, the appointment of three sets of trustees is made, one for the New Haven interest in the Boston & Maine, one for the Connecticut trolleys, and one for the Rhode Island trolleys. These trustees are instructed to sell the stock held by the New Haven system before certain dates set by the court, and to assist any bona fide effort to reorganize the properties. They are forbidden to countenance any attempt on the part of the New York, New Haven & Hartford Railroad or its interests to re-establish by indirect methods its old monopoly. Moreover, to make this more difficult, every purchaser of the stock to be placed on the market is required to execute an affidavit attesting that he is a bona fide purchaser and is not acting in the interest of the New Haven Railroad.

In the first place, the decree declares that the New York, New Haven & Hartford Railroad, the New England Navigation Company, the Boston Holding Company and the Providence & Danielson Railway have been parties to combinations in restraint of trade and are now monopolizing a part of such trade, consisting of transportation by railroad, electric railway and steamboat lines in New England.

As regards the Connecticut Company the trustees to deal with the 400,000 shares of stock of that company, which controls the electric railways in Connecticut, now in the hands of the New England Navigation Company, are Walter C. Noyes, Old Lyme; Lyman B. Brainerd, Hartford; Charles Cheney, South Manchester; George E. Hill, Bridgeport, and William W. Hyde, Hartford. In this case the trustees are to try to have the sale completed by July 1, 1919.

The trustees to deal with the Rhode Island electric railways are Rathbone Gardner, John O. Ames, John P. Farnsworth, Theodore Francis Green, and Charles C. Mumford, all of Providence. The New Haven is to assign to them 96,855 shares of the Rhode Island Company, and the New England Navigation Company is to assign 9132 shares and $600,000 of bonds of the Providence & Danielson Railway, and 7000 shares and $600,000 bonds of the Sea View Railroad. These, as in the case of the Connecticut Company, are to be sold at the request or consent of the New Haven; but if they are not so disposed of by July 1, 1919, a public auction will be held of the remainder under the order of the court. The full proceeds of the sales of the bonds of the Providence & Danielson Railway and of the Sea View Railroad are to go to the New England Navigation Company, and the proceeds of the sale of the stock of their companies and of the Rhode Island Company to the New Haven. The same liberty of exchanging any of these Rhode Island securities for others in connection with a reorganization scheme is given to these trustees as was provided for in connection with the Boston & Maine and the Connecticut trustees.

Concerning all these three sets of trustees the court takes notice that they will have expenses without having funds, so the court orders the New Haven to advance the money needed. The Holding Company trustees are limited to $15,000 a year, but no limitation is put upon the Connecticut or Rhode Island trustees.

It is also ordered that the trustees shall issue to the New York, New Haven & Hartford Railroad and to the New England Navigation Company negotiable certificates of their interests in the properties held by them, and regulations are laid down concerning the action and the responsibility of the trustees. Of these the most important is:

"Each body of trustees in electing directors of any company, which it controls, and in all other actions shall exercise all the powers herein vested in such body so as to assure a management solely in the interest of such company without regard to the interest of the New Haven Company or any other corporation or person, but with due regard to the public interest. If deemed desirable by such body it may cause its own members or any of them to be elected directors of any company."

Then the court orders the sale of a number of blocks of securities held by the New York, New Haven & Hartford Railroad or its subsidiaries, which have given it the control of important transportation facilities. Thus it orders the sale before July 1, 1919, of the New Haven's 53,981 shares of the Berkshire Street Railway. This sale, however, must not be held until the commonwealth of Massachusetts has authorized it, or the Federal Court has issued a further order concerning it at a hearing at which Massachusetts has been invited to be present. The New York, New Haven & Hartford Railroad is also ordered to sell before July 1, 1919, its 5000 shares and $678,000 of bonds of the New York & Stamford Railway and its rights to the stock of the Westchester Street Railroad, when issued, and the New England Navigation Company must sell before July 1, 1919, its rights to the capital stock of the Shore Line Electric Railroad, when issued, and the $13,709,000 of gold notes of the New England Investment & Security Company, which it now owns. None of these shares or other securities shall be sold to anyone in the interest of the New Haven.

Costs are to be paid by the New Haven, the New England Navigation Company, the Boston Holding Company, and the Providence & Danielson Railway.

At the recent directors' meeting of the New York, New Haven & Hartford Railroad William Skinner, a director since 1902, and Morton F. Plant tendered their resignations, which were accepted. As the annual meeting of stockholders will occur Oct. 28 no steps were taken to fill the vacancies.

RESOLUTIONS HONORING CAPTAIN McCULLOCH

The directors of the United Railways, St. Louis, Mo., have passed unanimously resolutions in part as follows, lamenting the death of Capt. Robert McCulloch, late president and general manager of the company:

"We have found it difficult to prepare a proper memorial of Robert McCulloch. He had that rare faculty which won the love of men, and we cannot think upon his death without distressing emotion. The spell of the living man is still upon us. We remember, too vividly, his many and varied excellencies, his bluff, hearty sincerity, his kindliness, generosity, charm, firmness and high integrity, to be mindful of the lesser qualities which made him useful to the corporation. Fortunately, its record contains the history of his achievements. Called to the management of its affairs at an alarming crisis, he extricated it from embarrassment and restored it to public favor. He won not only the respect but the affection of its employees. By his personal influence he prevailed over all factious opposition and quieted discontent. All men trusted him; his word was never broken. He was zealous to promote the general welfare and tried constantly to provide a service which should disarm hostility. He listened to grievances, and when he promised to redress them men were content to wait upon his effort. Year by year the corporation has grown in public favor. Yet he was never neglectful of its welfare. His vigilance was incessant. He worked long, without rest, striving continually to perfect its system and enable it to realize a fair return upon the investment. No one knew better than he that the corporation's welfare depended upon the excellence and economy of its service. By his labor he created a great system worthy of a great city, and none now wish to withhold from him the credit which is due to his performance."

Regarding Richard McCulloch, who has been appointed general manager to succeed Captain McCulloch, the St. Louis *Republic* said editorially:

"St. Louis has long known and esteemed Richard McCulloch for his own sake. He is an engineer of note and a man among men. But his advancement to the position of general manager of the United Railways will be especially pleasing to the community because it continues the McCulloch succession.

"For many years the man who wanted to see the president and general manager of the United Railways went to the offices of the company at Park and Vandeventer Avenues and climbed the stairs to the second floor. A door stood open at the end of the hall and just inside it a gray-haired man sat at a long table. This was Capt. Robert McCulloch, and the formalities of obtaining an interview with him consisted of stepping inside the door and stating one's business. Here he met all sorts and conditions of human beings, from the traction magnate to the wife of the discharged employee who had come to plead for "just one more chance" for Tom or Bill. Here he sympathized with the unfortunate, helped the worthy man by giving him a chance to help himself, treated with a tact peculiar to himself the fussy and the unreasonable and entered with energy into every plan for a better, happier or wiser St. Louis in which it was possible for the United Railways to help.

"It is announced in the press that Richard McCulloch will continue to occupy his customary quarters at the offices of the United Railways. This is very much his own affair; but if the son who succeeds his father as executive head of our great system of surface transportation should, at his convenience, see fit to take that same place at the long table opposite the open door, those of us whose philosophy has still room in it for that outdated institution, the family, would be glad of it.

"The *Republic* extends its felicitation and best wishes to the new general manager. And it is unaffectedly glad that the McCulloch succession is to be continued."

HEARING ON BOSTON TRANSPORTATION IMPROVEMENTS

The Massachusetts Public Service Commission opened hearings on Oct. 20 upon a resolve of the last Legislature providing for an investigation of transportation conditions in Greater Boston and a subsequent report as to recommended improvements. The investigation is the direct outcome of the proposition of P. F. Sullivan, president of the Bay State Street Railway, last spring that legislation be enacted consolidating the Bay State company and the Boston Elevated Railway, with the object of establishing a single comprehensive transit system in the metropolitan district. All the principal steam and electric railways operating in Boston and vicinity were represented at the hearing, which was devoted mainly to an outline of desirable changes presented by W. C. Ewing, of the Boston City Planning Board. At a later hearing the companies will be given the opportunity to present any suggestions and facts which they deem pertinent.

Chairman McLeod said that the commission had lately acquired much data relative to urban transportation conditions through the visit of the chairman and Commissioner Stone to Madison, Wis., Chicago, Buffalo, Cleveland, Toronto and Indianapolis. The engineers and accountants of the commission have been investigating the accounts and relations of the Bay State Street Railway and the Boston Elevated Railway. For the planning board, Mr. Ewing pointed out that the problem of metropolitan transit is a terminal question. Within the area bounded by Broadway extension, Pleasant and Charles Streets and the harbor front, are twenty-seven subway, tunnel and elevated railway stations, and when the Dorchester tunnel is in operation, it will be possible to deliver every street railway passenger within a four-minute walk of his destination inside the business district. There are only three steam railway stations in the above area and one of these is approached by a ferry. The speaker said that the planning board favored state ownership of the transportation system. Representatives from the city of Malden urged the construction of a subway to that suburb, the electrification of various lines of the Boston & Maine Railroad, and an arrangement for the use of the Saugus branch of the latter by the Boston Elevated Railway. Residents of Watertown advocated the placing of the municipality within the 5-cent fare limit and the Roxbury board of trade urged relief from congestion at the Dudley Street elevated terminal.

CLEVELAND RAILWAY STOCK INCREASE AND TRAINMEN'S ARBITRATION

The Cleveland (Ohio) Railway was notified on Oct. 17 that its application for authority to issue $2,382,600 additional stock had been granted by the Public Utilities Commission.

The company has selected Attorney Charles Higley to represent it in the arbitration proceedings with the platform men. As already announced, Judge Willis Vickery will represent the men, but so far the two have not been able to agree on the third member.

Councilman Mayers has revived the measure to require street cars to stop on the near side of all street intersections. Peter Witt, street railway commissioner, is opposed to the plan, while Director of Public Safety Benesch favors it because he feels that it will enable the department to inaugurate the safety zone system in all parts of the city.

Many councilmen are opposing the proposed crosstown line on East 123d and East 125th streets, between Superior and St. Clair Avenues. They say the line will accomplish no other purposes than to increase the value of certain lands real estate men hold along the proposed line. A real estate firm is now building the streets that are to be used for the line, and expects to have them finished in the spring of 1915. According to Mr. Witt, the cost of the proposed line will be about $75,000.

Mr. Witt has made a new proposition to East Cleveland to prevent that municipality from resorting to its contract which requires through service to West Ninth Street, instead of the Public Square, where cars are looped at present. He has agreed to put on a four-minute service to the Windermere carhouse, with a three-minute service during rush hours, as well as to add fifteen runs between East Ninth Street and the East Cleveland Y, which is the eastern boundary line of the town. The proposal was recommended by E. A. Binyon, city solicitor of East Cleveland.

ALLEN & PECK, INC., TO MANAGE BUFFALO, LOCKPORT & ROCHESTER RAILWAY

C. D. Beebe, president of the Buffalo, Lockport & Rochester Railway, has announced that the company had accepted the resignation of H. C. Prather as general manager, and had made an arrangement with Allen & Peck, Inc., to take over the operation and management of the property, reporting to the president and the executive committee. Under the arrangement, C. Loomis Allen will become the active member of the firm of Allen & Peck on the property. He will be elected as vice-president of the company, in charge of operation. James P. Barnes, general manager of the Syracuse & Suburban Railway, will become resident general manager of the Lockport road, with headquarters probably in Rochester.

Mr. Beebe and the other officers and members of the board of directors regard the arrangement as one that probably will be of much advantage to the company, as through it they secure the services of men of high character and ability to take charge of the active operation and management of the road. Within the last few months the company has commenced the operation of its cars between Rochester and Buffalo. It also has recently closed a contract with Wells

Fargo Express whereby it will operate a through express service between Rochester and Buffalo, as well as inaugurating a package freight business of its own. The company, in connection with the Empire United Railways, has also made a contract with the Erie Railroad whereby after Nov. 1 it will use the new Erie freight station as a terminal for Rochester business. The company is now using the Erie passenger station for passenger traffic.

Mr. Prather has been with the Buffalo, Lockport & Rochester Railway ever since it began operations. Up until ten months ago, when he became general manager, he held the position of master mechanic and was in charge of the maintenance of rolling stock and other interests. He has been appointed local manager of the Rochester Division of the Empire United Railways.

For the present, the position of general manager of the Syracuse & Suburban Railroad, made vacant by the transfer of Mr. Barnes to the Lockport line, will not be filled. Edward F. Peck, president of Allen & Peck, Inc., will assume temporary charge of the road.

MR. HEWITT APPOINTED GENERAL MANAGER UNITED TRACTION COMPANY

On Oct. 1 C. F. Hewitt, who has been assistant general manager of the United Traction Company, Albany, N. Y., assumed the duties of general manager, succeeding James F. Hamilton, who will devote all of his time in future to the Schenectady Railway, which he has managed jointly with the United Traction Company. Mr. Hamilton, for a long time, has been desirous of lessening his duties and responsibilities and consented to continue his work with the United Traction Company until Mr. Hewitt had become familiar with local conditions in Albany.

Mr. Hewitt was formerly vice-president and general manager of the Des Moines (Ia.) City Railway and Inter-Urban Railway. He entered the electric transportation field in 1895 as superintendent of the Elmira Water, Light & Railroad Company. In 1900 he went to Indiana as general manager of the St. Joseph & Elkhart Power Company and the Elkhart Electric Company, being principally interested in the management of the latter company in a hydroelectric development of the former company. Upon the completion of this work Mr. Hewitt became operating manager of the St. Joseph Railway, Light, Heat & Power Company, St. Joseph, Mo., remaining there until 1908, at which time he was transferred by the owners of the St. Joseph property to the operating management of the railway, lighting and other public utility properties of the East St. Louis & Suburban Company at East St. Louis, Ill. In July, 1912, Mr. Hewitt entered upon his duties with the Des Moines company as already outlined.

Mr. Hamilton entered the transportation department of the International Railway, Buffalo, N. Y., in 1896, and after serving in various positions was placed in charge of one of the largest stations. He resigned his position with that company in 1902 to become assistant superintendent of the Schenectady Railway, and was appointed superintendent of that company in 1909. Two years later Mr. Hamilton was engaged as general superintendent of the United Traction Company, and was retained by the Schenectady Railway in an advisory capacity. In 1912 he was appointed general manager of both companies.

New Line Opened in California.—The first section on the Sacramento Valley Electric Railway, Willows, Cal., which extends from Dixon and connects with the Oakland, Antioch & Eastern Railway, has recently been placed in regular operation.

Short Strike in East Liverpool.—Fifty union firemen, boiler tenders and ash haulers of the East Liverpool Traction & Light Company, East Liverpool, Ohio, struck on the morning of Oct. 6 because the company refused to reinstate eleven men who had been discharged. The places of the strikers were filled at once and little inconvenience was caused.

Sliding Wage Scale Rejected in Albany.—The employees of the United Traction Company who are members of the unions in Albany and Troy, N. Y., have by vote rejected the proposal of the company to put into effect the sliding scale of wages on these divisions. In June the men asked for a flat rate of 35 cents an hour, an increase of 8 cents an hour over the wages paid previously. It is expected that the point in dispute will now be submitted to a board of arbitration.

Public Utility Commission Decisions.—The Public Utility Commission Reports Company, Stock Exchange Building, Chicago, Ill., proposes to undertake the work of publishing the reports of the public service commissions arranged exclusively for the use of public utilities. All decisions affecting steam railroads will be eliminated unless they have a bearing upon pubic utilities. The decisions will be segregated into classes and indexed so as to be available for ready reference.

Service Conference in Pittsburgh.—At a recent conference between the members of the City Council, Mayor Armstrong and the city solicitor of Pittsburgh, Pa., the answer of the Pittsburgh Railways to the bill of complaint was discussed, and the Mayor was authorized to arrange a conference with officials of the company. The letter of J. D. Callery, president of the company, reviewing street railway conditions in the city was published in abstract in the ELECTRIC RAILWAY JOURNAL of Oct. 17, page 936.

Short Strike in Fort Smith.—The trainmen of the Fort Smith Light & Traction Company, Fort Smith, Ark., have returned to work following an agreement reached with the officers of the company. The strike continued for a period of twenty-four hours. Under the terms of the settlement the fifteen employees who were discharged recently will be reinstated, the seniority rule will be put in force, and in future all disputes will be referred to arbitration if the grievance committee which is appointed by the men cannot reach an agreement with the officers of the company.

The Detroit Appraisals.—In addition to the appraisal of the properties of the Detroit (Mich.) United Railway within the one-fare zone now being made by Prof. E. W. Bemis for the city railway commission of Detroit, Professor Cooley, of the University of Michigan, is now engaged in an appraisal of the properties not only within the city but outside as well. Professor Cooley is making the appraisal for the State Railway Commission. By reason of having practically finished his appraisal of the Pere Marquette Railroad, Professor Cooley has been able to turn a large number of his experienced men on the Detroit United Railway work and it is now thought the appraisal of these properties will be finished before Christmas.

San Francisco Municipal Railway Estimates.—The San Francisco (Cal.) Municipal Railway bond fund is insufficient for the construction of the new lines for which it was voted, according to a report by Leonard Leavy, bookkeeper of the Public Works Board. The deficit is attributed to the extra cost of the cable system for the Church Street hill, which the supervisors lately ordered. The bonds of the issue of $3,500,000 that have been sold amount to $2,642,500. They brought a premium of $23,658. Whether the remaining $857,500 can be sold now is considered doubtful because of market conditions. For work already undertaken $1,915,567 has been expended. For final payments on contracts and finishing the present work, $718,226 is required. For new work the city engineer's estimate is $1,020,240, making a total of $3,654,033. If the remaining bonds are sold the available cash will total $3,523,658, leaving a deficit of $130,374.

Conditions Normal on Joplin & Pittsburg Railway.—The receipts of the Joplin & Pittsburg Railway, Pittsburg, Kan., for the first few weeks after the resumption of traffic, succeeding the strike of nearly three months, have been quite up to the receipts of the same period last year. The line is now operating on all its branches. The company is, however, using only two of the power houses, those at Pittsburg and at Franklin. It gets power from the Empire District Electric Company, from the Joplin station, through substations a short distance north of Joplin, at Asbury, half way between Joplin and Pittsburg, and at Scammon. The Joplin & Pittsburg Railway maintained a power house at Scammon before the strike. At that time arrangements had already been made for the transformation of this station into a substation of the Empire Company. The Empire's substation equipment had already been put into the building and when traffic on the Joplin & Pittsburg was resumed the substation immediately began to supply current. The power house equipment in the Scammon building was not disturbed.

City Borrows from Chicago Traction Fund.—The Chicago City Council finance committee in seeking a means of raising $1,000,000 to insure the completion of a municipal recreation pier, devised a plan whereby this amount could be borrowed from the traction fund for four months, municipal bonds being deposited as security. At the present time this fund, which now includes approximately $14,000,000, is drawing 2¼ per cent interest when it is invested in anticipation of tax warrants. According to the new plan, the $1,000,000 fund for the completion of the recreation pier will draw 4 per cent interest. The finance committee decided to adopt this way of raising the necessary funds because bonds could not be sold except at a discount.

Western Massachusetts Transportation Hearings.—The transportation commission appointed by Governor Walsh of Massachusetts has been holding continued hearings within the past few days in the western part of the State. A strong general sentiment has developed in behalf of the construction of additional electric railways in Berkshire and Hampden Counties, the present train service and highway facilities being regarded as unsatisfactory. It was urged that if such lines could be built, water powers now running to waste could be utilized and a widespread movement started toward prosperity. It is expected that an appeal will be made to the next Legislature to have the State finance electric railway development in the Berkshire district unless private capital can be found to undertake the work.

Plans for Conference of Mayors.—Mayor Blankenburg of Philadelphia has been notified by the mayors of seventy-five cities throughout the country that they will attend the conference to be held in Philadelphia on Nov. 12, 13 and 14 to discuss public policies as to municipal regulation and control of public utilities. A general committee of well-known Philadelphians has been named by the Mayor to perfect plans for the conference and it has just agreed on a preliminary program. It is planned to have the sessions begin on the evening of Nov. 12, with a reception to mayors and delegates. The Friday morning session will be given over to a discussion of practical utility problems. In the afternoon the discussion will cover the regulation of utilities. Both these session will be held in the Bellevue-Stratford. The Friday evening session will be held in the auditorium of the Central High School and the subject for discussion will be local and state regulation of municipal utilities. Saturday morning, Nov. 14, in the Bellevue-Stratford, municipal ownership and operation will be discussed. In the afternoon the topic will be "Elements in the Constructive Utility Program." The evening session will adjourn to Witherspoon Hall, when holding companies and public utilities will be discussed by experts under the auspices of the American Academy of Political and Social Science.

Plea for Inventory Rejected.—The Supreme Court of Nebraska has decided against the State Railway Commission by refusing to issue a writ of mandamus to compel the Omaha & Council Bluffs Street Railway to file with the commission an inventory of its property. The company contended that a street railway does not come within the scope of the physical valuation law and that an inventory such as was desired by the commission would cost the company $7,500. A complaint asking for a reduction of car fares in Omaha is pending before the commission. The syllabus of the court's opinion follows: "The words 'railroad' and 'railway' as used in the physical valuation act (laws of 1909) held not to include street railways. Since such act declares that 'the term public service corporation when used in this article shall mean and embrace' certain named classes of such corporations, no other class of public service corporation is within its terms. The proper object of a court in construing a statute is to give effect to the intention of the Legislature, and where the language used in an act is ambiguous resort may be had to the history of its passage through the Legislature, if this throws any light on the meaning of the language used therein. When the Legislature has, upon the effort being made therein, refused to include certain classes of public service corporations in a physical valuation statute, the court will not include them therein by construction."

PROGRAMS OF ASSOCIATION MEETINGS

Central Electric Railway Association

The next meeting of the Central Electric Railway Association will be held at Fort Wayne, Ind., on Nov. 19.

New York Electric Railway Association

An executive committee meeting of the New York Electric Railway Association was held on Oct. 22 at the Transportation Club, New York. Those present were James F. Hamilton, Schenectady; John J. Dempsey, Brooklyn; S. Walter Mower, Cooperstown; William O. Wood, Long Island City; Frank Hedley, New York, and Charles C. Dietz, Brooklyn. It was decided not to hold a quarterly meeting in the month of December this year on account of the closeness of the annual meeting and the mid-year meeting of the American Electric Railway Association. The early spring meeting of the New York Electric Railway Association will, however, be held as usual. Other matters of importance were considered by the committee.

National Association of Railway Commissioners

The twenty-sixth annual convention of the National Association of Railway Commissioners will be held in the hearing room of the Interstate Commerce Commission in Washington, D. C., beginning Nov. 17. It is hoped that all the reports of the committees will be completed and sent to the secretary for printing and distribution at least thirty days in advance of the meeting. This will enable members to be better prepared intelligently to discuss the reports. James S. Harlan, chairman of the Interstate Commerce Commission, will deliver the address of welcome. Charles A. Prouty, director of valuation, will discuss the question of the valuation of common carriers subject to the act to regulate commerce. As no other special topics or addresses are scheduled, the time of the convention will be largely directed to the discussion and consideration of committee reports.

Association of Railway Electrical Engineers

The seventh annual convention of the Association of Railway Electrical Engineers will be held at the Hotel La Salle, Chicago, Oct. 26 to 30. During the term of the sessions the nineteenth floor of the hotel will be given over to exhibits of electrical manufacturers and supply dealers making a specialty of equipment for car-lighting and railroad service.

The technical program of the convention will open Tuesday morning, Oct. 27, with an address by the president, C. R. Gilman, illuminating engineer of the Chicago, Milwaukee & St. Paul Railway, to be followed by the report of Secretary Joseph A. Andreucetti, Chicago & Northwestern Railway, Chicago. At the afternoon session reports will be submitted by the committees on loose-leaf binders for filing specifications and keeping specifications and standards to date, J. R. Sloan, chairman; on reciprocal relations, L. S. Billau, chairman; on specifications for wire crossings for potentials above 100 volts, J. R. Sloan, chairman, and on data and information, Edward Wray, chairman.

On Wednesday at the morning session reports will be submitted by the committees on standards, D. J. Cartwright, chairman, and on headlamps, C. R. Sugg, chairman, followed by a paper entitled "Communication to and Between Trains by Telegraph-Wireless, Telephone-Wireless and Telephone," by F. H. Milner, Union Pacific Railway, Omaha, Neb. At the afternoon session reports will be submitted by the committees on industrial trucks; on electric traction, and on specifications.

On Thursday at the morning session there will be reports from the committees on axle equipment, H. R. Bucks, chairman; on head-end equipment, K. R. Hare, chairman, and on standard rules for car wiring, S. W. Everett, chairman. At the afternoon session the committee reports on outside construction and yard lighting, H. M. Warren, chairman; on illumination, L. S. Billau, chairman, and on shop practice, G. W. Cravens, chairman, will be presented.

On Friday at the morning session a report is scheduled from the committee on yard facilities for charging, D. B. Pastorius, chairman, to be followed by the election of officers. There will be a dinner-dance on Friday evening.

Financial and Corporate

RECENT FINANCIAL TENDENCY

Discussion of plans for opening the New York Stock Exchange has been revived by the visit to this country of Sir George Paish, the English financial authority. Except that general conditions have improved materially since the declaration of war, practically the same problems present themselves for settlement in connection with the reopening that existed weeks ago. The governing committee of the exchange has not yet gone on record, and the discussion regarding the reopening is purely speculative, representing what particular individuals think may transpire or what they would like to have take place.

Pronounced ease was the feature of the market for foreign remittances on Oct. 21. It was reflected in a decline of demand sterling from 4.95¼ at the beginning to 4.94¾. Cable transfers fell to 4.95¼. The Continental exchanges showed sympathetic weakness. Francs declined to 5.08½ for checks and 5.08 for cables, while marks went down to 91¼ for checks and 91½ for cables. Loans in time money were negotiated on Oct. 21 in New York in small amounts at rates ranging from 6 to 7 per cent, the maximum figure applying principally to the shorter maturities. Call money was put out in a few small lots at 6 per cent.

CHANGE IN STOCK CONTROL

The protective committee of the preferred shareholders of the New England Investment & Security Company, Springfield, Mass., composed of Moses Williams, Jr., Henry B. Cabot and E. V. R. Thayer, has concluded the purchase of the 1000 shares of common stock held by Sanderson & Porter, New York. Previous reference was made to this impending purchase in the ELECTRIC RAILWAY JOURNAL of Sept. 5. This stock, which was purchased by Sanderson & Porter in the summer of 1913, carried with it practical control of the New England Investment & Security Company, the vehicle through which the New York, New Haven & Hartford Railroad owned the electric railways in Springfield, Worcester and other towns in the western part of Massachusetts. The New Haven's interest is now represented by $13,700,000 of notes due in 1924. According to the New Haven dissolution decree, abstracted elsewhere in this issue, the railroad must also dispose of these notes before July 1, 1919, to parties not interested in its own organization.

Francis H. Dewey and Alexander G. Bullock, Worcester, and E. V. R. Thayer, Fitchburg, have been elected trustees in place of Sanderson & Porter's representatives, so that now the entire board of trustees represents the preferred stockholders. There are 40,000 shares of non-voting preferred stock outstanding, which are owned by about 1000 holders and on which dividends at 4 per cent are guaranteed by the New Haven Railroad. The purchase money was raised by a contribution of $10 a share by the preferred stockholders, which provided enough to carry the purchase through, although the purchase price itself is unknown.

Although no formal announcement has been made by the new management, Mr. Dewey in an interview expressed himself as follows:

"There will be no change of management at present. No attempt will be made to sell bonds or stock or to reorganize the properties, for the money market is not now in a condition for people to be interested in investments. As to the complete abolition of holding companies and what will be done in the matter of reorganization, these are matters that the trustees will decide in good time and of which the public will be kept informed through the newspapers."

Under the former arrangement the owners of the 1000 common shares selected four of the seven trustees and the owners of the 40,000 preferred shares selected only three. For several years all the properties, operating about 420 miles of street railway, have been controlled now by one set of owners of common stock and now by another set, the preferred stock, largely held by the investors in Springfield, Worcester and Boston, being legally in the position of a minority. Recently, however, several influential preferred shareholders became active in forming a protective committee, which has brought about the above change of control.

ANNUAL REPORTS

Boston Elevated Railway

The Boston (Mass.) Elevated Railway earned dividends of $1,193,970 during the fiscal year ended June 30, 1914, with a surplus of $63,199 for the period. The company's figures of operation, as reported to the Massachusetts Public Service Commission, showed operating revenues $820,709 greater than in the preceding year. The operating expenses were only $162,280 larger, yielding an increase of $658,428 in the net income from operation. Deductions from income increased $98,824 during the year. The deficit for 1913 was $496,377, and for 1912 it was $491,632, both of which are to be ascribed to the effect of the strike of 1912. There was no increase in the capital stock, which totals $23,879,400.

Below is a summary of the company's return to the commission, compared with the results for the preceding year:

	1914	1913
Operating revenue	$17,629,617	$16,808,908
Operating expense	11,297,862	11,135,581
Net income from operation	$6,331,755	$5,673,327
Miscellaneous income	156,361	159,419
Total income	$6,488,116	$5,832,747
Fixed charges	5,230,948	5,131,124
Balance	$1,257,168	$700,622
Dividends	1,193,970	1,197,000
Surplus	$63,198	*$496,377

---

*Deficit.

Traffic and operating statistics for the two years ended June 30 compare as follows:

	1914	1913
Revenue car-miles	57,990,436	57,784,319
Revenue passengers	343,181,049	326,352,863
Employees	9,842	9,882
Maintenance of way and structures	$1,694,072	$1,761,842
Maintenance of equipment	$1,331,339	$1,282,655
General expenses	$1,729,665	$1,773,597
Traffic expenses	$13,157	$16,048
Transportation expenses	$6,529,626	$6,301,400
Operating ratio	64.08	66.25

New York Railways

The comparative statement of income, profit and loss of the New York (N. Y.) Railways for the years ended June 30, 1913 and 1914, follows:

		1914	1913
Gross operating revenue		$13,860,837	$14,065,158
Operating expenses		8,759,973	8,775,961
Net operating revenue		$5,100,864	$5,289,197
Taxes		1,092,105	1,169,895
Income from operation		$4,008,759	$4,119,302
Non-operating income		434,200	410,029
Gross income		$4,442,959	$4,529,331
Income deductions:			
Interest on underlying bonds, rents, etc.		$2,674,509	$2,695,555
Interest on New York Railways first real estate and refunding mortgage 4 per cent bonds		651,838	651,838
Total		$3,326,347	$3,347,393
Balance		$1,116,611	$1,181,938
Add:			
Surplus, June 30, 1913 and 1912:			
At beginning of year as adjusted	$46,101		
Additions during year	21,322		
		67,423	54,327
Total available for interest on New York Railways adjustment mortgage 5 per cent income bonds		$1,184,034	$1,236,265
Deduct:			
Interest on New York Railways adjustment mortgage 5 per cent income bonds		1,112,675	1,190,164
Surplus		$71,357	$46,101
Add:			
Net income from Williamsburg Bridge local car operations			12,129
Surplus June 30, 1914			$83,486

NOTE.—For purposes of comparison the operating expenses for the year ended June 30, 1913, are adjusted to include reserve for maintenance and depreciation.

Revenue from transportation for the year, excluding Williamsburg Bridge local car operation, was $13,421,681, a decrease of $184,172, or 1.35 per cent. For the first six months of the fiscal year there was an increase in both gross and net earnings and in the number of passengers carried. During the second six months, however, there was a decrease on account of the snow storms during February and March, the generally less favorable weather conditions and the widespread business depression. The aggregate loss to the company on account of the storms, in conduit cleaning, snow removing, damage to pavement and track structure, and on account of excessive wear caused by vehicular traffic, including loss of passenger revenue, was approximately $500,000. The interruptions caused by the city subway construction also had a harmful effect upon some of the company's revenues, for although during the six months ended Dec. 31 all the so-called north and south lines showed a gain in receipts, the Lexington Avenue line suffered a heavy loss on account of the fact that delays thus caused had diverted traffic from that line.

The other street railway operating revenues for the period were $439,157, a decrease of $20,148, or 4.39 per cent. The three largest items of revenue under this heading were advertising, $325,000; sale of power, $90,703, and rent of tracks and terminals, $15,969. The total decrease was accounted for by decreases in the sale of power and equipment rentals from other companies approximating $50,000, which was partly offset by increases in advertising and rent of tracks and terminals, approximating $30,000.

The operating expenses decreased $15,988, or 0.18 per cent. The operating expenses for 1914 and 1913 include amounts reserved for maintenance and depreciation, the reserve for the year ended June 30, 1914, being $324,773, a decrease as compared with 1913 of $376,936. The charges for paving included in operating expenses amounted to $555,191, an increase over 1913 of $167,328. There was also an increase of $146,184 in the cost of snow removal. The amount actually expended for maintenance of track and roadway, electric line, building structures, etc., was $1,614,443, an increase over 1913 of $397,684. The expenditures for maintenance of equipment amounted to $832,951, a decrease as compared to 1913 of $61,613. The total maintenance expenditures increased $336,071 over the preceding year. The extraordinary charges in the nature of improvements and replacements included in the maintenance accounts amounted to $707,322, an increase of $145,260.

Taxes assignable to street railway operations decreased $77,789, or 6.65 per cent. All classes of taxes as accrued showed decreases, the greater portion of the reduction applying to real estate, special franchise and gross earnings and taxes. The combined cost of claims for the current year and those arising out of operation during the receivership and liquidated during this year amounted to approximately 6.4 per cent of the gross passenger revenue, as compared to 6.6 per cent last year. The number of serious personal injuries was reduced more than 12.8 per cent and the total number of accidents 10.4 per cent. Plaintiffs won only 34 per cent of all cases tried in the courts. The company voluntarily settled 3316 claims for $273,152 before suit was brought and compromised 1058 suits for $234,687 before trial, leaving as a result of contested suits 185 judgments paid, amounting to $58,519.

The reserve for injuries and damages during the first six months of the year was reduced from 8 per cent to 7½ per cent of the passenger revenue, but restored to 8 per cent by order of the Public Service Commission. The percentage of 7½ per cent, however, was adopted during the last six months. The report states that it usually takes five years to liquidate and extinguish completely all liability for accidents in any year and that no adjustment can be had as to the reserves for 1912 and 1913 until the liability for these years shall have become extinguished by payment, litigation or the statute of limitations. It is also stated that the new workmen's compensation law will increase the cost of employees' accidents, so that no considerable change in accident reserve should be made at this time.

The company showed a net increase of $24,171, or 5.89 per cent in operating income, which is accounted for by the additional interest revenue received on special funds. The profit and loss surplus amounting to $83,486 was composed of $83,254 interest on the $650,000 note of the joint reorganization committee assumed by the company Oct. 3, 1912, and an undistributed balance of $232.

During the year the company completed and placed in service 175 stepless cars, 45 storage battery cars and 29 electric trucks. The report contains tables and schedules showing the capitalization of the company, the railroads leased and operated under agreement and the welfare work conducted by the company. In regard to the workmen's compensation law, it is stated that the difference between insurance in a stock company or the state fund and self-insurance appeared so disproportionate that when allowance was made for medical expense, the economy seemed to be on the side of self-insurance.

The report emphatically states that the very large expenditure for street paving in the past and at present is extraordinarily burdensome and interferes with the proper carrying out of plans for the physical improvement of the company's property. The company feels that a change in paving requirements is not only justified by existing conditions, but it is absolutely necessary to conserve its revenues for rendering efficient transportation service. It is believed that one party, preferably the city, should be responsible for the condition of the paving in all city streets from curb to curb, and that the railways should make some satisfactory arrangement with the city to pay a reasonable and proper proportion of the maintenance cost, say on the basis of a fixed sum per running foot of single track per annum, which would relieve the companies entirely of their existing paving obligations and place in the hands of the city the question of paving or repaving the public streets.

Birmingham, Ensley & Bessemer Railroad, Birmingham, Ala.—The independent bondholders committee of the Birmingham, Ensley & Bessemer Railroad announced on Oct. 9 that A. R. Patterson, general auditor Stone & Webster Management Association, whom they had employed to investigate the affairs of the company, had been informed by the general auditor of the railway that he was unable to give any definite information regarding the railways' vouchers, for the books were being examined by certified public accountants employed by other interests.

Boston (Mass.) Elevated Railway.—Charles P. Hall has resigned as a director of the Boston Elevated Railway on account of his appointment as a trustee of a majority of the Boston & Maine Railroad stock under the recent decree entered in the government suit against the New York, New Haven & Hartford Railroad.

Brooklyn (N. Y.) Rapid Transit Company.—The Brooklyn City Railroad recently anticipated a payment of an instalment of $100,000 due on account of the debt to the Brooklyn Heights Railroad under the terms of the settlement for $1,650,000 of the suit brought against it by the latter. There is now said to be due about $400,000 of the amount.

City Service Company, New York, N. Y.—In a recent letter to stockholders H. L. Doherty, president Cities Service Company, stated that the machinery of credit in this country is gradually being adjusted to overcome the strain caused by war conditions but that there have been no developments which would warrant the directors in changing their policy of deferring dividends. According to Mr. Doherty, since July 30 action has been taken by various corporations in this country, discontinuing, deferring or reducing payments of interest and dividends on approximately $2,000,000,000 of capital and to the extent of practically $100,000,000 in annual payments to security holders. Every action of this character is depressing but should not be interpreted as an indication of added difficulties. On the whole, the properties of the Cities Service Company are making a satisfactory showing, with encouraging news from time to time of added improvement. With the exception of sales of crude oil, there has been no marked effect to lessen the earnings of the various properties. Concerning the recent injunction against the 3-cent fare ordinance in Toledo, Mr. Doherty said: "The effect of this restraining order will be to increase substantially the earnings of the Toledo street railway lines. It is very significant that the decision of Judge Killits was received with general approval by the Toledo public. Since the Toledo properties came under the present management the feeling toward the local utilities has been steadily changing until at present relations are extremely cordial."

Cleveland (Ohio) Railway.—As noted in the ELECTRIC RAILWAY JOURNAL of Oct. 17, the Ohio Public Utilities Commission has authorized the Cleveland Railway to issue $2,382,600 of common stock to be sold for the highest price obtainable, but not for less than par. The proceeds are to be used for the following additions, extensions and permanent improvements: land for terminals, $50,000; buildings, $1,065,000; track, $585,000; power, $284,500, and rolling stock, $400,000.

Columbus Railway, Power & Light Company, Columbus, Ohio.—The Ohio Public Utilities Commission on Oct. 17 granted the Columbus Railway, Power & Light Company permission to issue $7,876,000 of first mortgage gold bonds or an equal amount of 4 per cent preferred stock to refund outstanding bonds of its underlying companies.

Empire United Railways, Syracuse, N. Y.—C. W. Seamans, New York, W. A. Jones, Newark, and J. M. Gilbert, E. I. Edgcomb, and A. H. Cowie, all of Syracuse, have been elected directors of the Empire United Railways to succeed other men who acted as temporary directors. E. D. Metcalf has resigned as vice-president and a director.

Eastern Texas Electric Company, Beaumont, Tex.—Stone & Webster, Boston, are offering for sale at 98½ and interest, to yield about 6.9 per cent, three-year 6 per cent notes of the Eastern Texas Electric Company, due July 1, 1916. The notes are callable as a whole at 100 and interest on any date at thirty days' notice. The notes are a direct obligation of the company, which covenants that, if any new lien is placed on the property, the notes shall be secured equally with the new obligation. The notes are followed by $1,400,000 of 6 per cent preferred stock and $1,400,000 of common stock.

Humboldt Transit Company, Eureka, Cal.—The Railroad Commission of California has rendered a decision authorizing the Humboldt Transit Company to issue and pledge $50,000 of first mortgage 5 per cent bonds with the Pacific Coast Casualty Company as collateral security for a surety bond.

Long Island Railroad, New York, N. Y.—The Public Service Commission of the Second District of New York has approved an issue of $1,000,000 of the Long Island Railroad's 5 per cent gold equipment trust obligations, series A. The total issue will be for $1,060,000 to be sold at not less than par and accrued interest, pursuant to an arrangement with the Fidelity Trust Company and Edward P. Gest as trustee. The proceeds, plus a cash payment of $125,000, will be used in the acquisition of the following equipment: Twelve steel passenger cars, three steel passenger and baggage combination cars, forty steel motor passenger cars, fifteen steel motor passenger and baggage cars, twenty steel baggage and express cars, four steel baggage and mail cars, and three motor passenger, baggage and mail cars. The car trust certificates, guaranteed principal and interest by the Long Island Railroad, are to be taken up in ten annual payments of $106,000 and interest.

New York (N. Y.) Railways.—The following committee has been formed to represent large holdings of the New York Railways thirty-year 5 per cent adjustment mortgage income bonds: John P. Kingsley, president New York Life Insurance Company; William A. Day, president Equitable Life Assurance Society; Haley Fiske, vice-president Metropolitan Life Insurance Company, and Allan Ford, president State Street Trust Company, Boston. The committee announces that the bondholders are entitled to vote for and elect five directors at the annual meeting in December, and that it will receive proxies for such election.

Northampton (Mass.) Street Railway.—The stockholders of the Northampton Street Railway have elected William A. Stevenson, Florence, and Charles E. MacIntosh, Holyoke, directors to succeed N. D. Winter, Springfield, resigned, and the late W. S. Loomis, Holyoke.

Northern Electric Railway, Chico, Cal.—Judge Dooling in the United States District Court of San Francisco on Oct. 5 decided to appoint John P. Coghlan, attorney for the Pacific Gas & Electric Company, as receiver of the Northern Electric Railway. Mr. Coghlan is reported as not intending to make any changes in personnel. According to a circular issued by the Sloss Securities Company, when the trustees were appointed it was estimated that the revenues of the Northern Electric Railway would provide for betterments and interest except for an estimated shortage of from $200,000 to $250,000, which should be made out of the revenues on the Scloss Securities Company. In February and May, 1914, the trustees paid the note interest, but unusual rains and floods made extensive repair work necessary and the operating revenues also did not keep pace with the estimate. On June 1 the note interest was defaulted and since that time, notwithstanding substantial economies effected, earnings continued to fall off, the decrease being most marked after the outbreak of the European war. Not only were the revenues insufficient to meet the interest on underlying bonds due Oct. 1, but they also failed to provide for the necessary maintenance of the physical properties. In view of these conditions a receiver was necessary, but it is hoped to terminate the receivership as soon as a plan of reorganization can be agreed upon. At a recent meeting of creditors five protective committees were appointed to look after interests of the holders of the different classes of securities and of the unsecured creditors.

Oakland, Antioch & Eastern Railway, Oakland, Cal.—The Railroad Commission of California has authorized the Oakland, Antioch & Eastern Railway to pledge $105,000 of first mortgage 5 per cent thirty-year bonds as collateral for a note of $62,500, provided the bonds be returned to the treasury upon the collection of the assessment delinquent on Oct. 8.

Pacific Gas & Electric Company, San Francisco, Cal.—The Pacific Gas & Electric Company is continuing its public offering of a block of its immediate issue of $12,500,000 of new first preferred cumulative 6 per cent stock at the original price of 82½, yielding 7.27 per cent on the investment. About $9,000,000 of this stock already has been sold to more than 3500 purchasers.

Richmond & Henrico Railway, Richmond, Va.—Carrying out the order of Judge Crump on Sept. 16 directing the sale of the properties of the Richmond & Henrico Railway, unless the company paid by Sept. 26 past-due interest of $250,000 on its bonds, Commissioners Samuel L. Kelley and Samuel A. Anderson have served notice that they will sell the property at public auction on Nov. 5. In accordance with the court order, the property will be disposed of as an undivided whole. Besides 7½ miles of railway track in the city of Richmond and a railway franchise, the holdings embrace valuable viaducts, a power house, carhouses, rolling stock and other railway appurtenances. The sale will bring to a conclusion the proceedings brought against the railway in June, 1913, by the Union Trust Company, Ltd., Toronto, Can., underwriter of its bond issue. At that time Judge Crump appointed the Virginia Trust Company as receiver, and this company has operated the road for more than a year, issuing receiver's certificates to meet expenses of operation.

San Diego (Cal.) Electric Railway.—The Railroad Commission of California recently authorized the San Diego Electric Railway to execute a mortgage to the Union Trust Company, San Francisco, to secure an authorized issue of $10,000,000 of general first lien 5 per cent forty-year sinking fund gold bonds and to issue thereunder $4,497,000 of bonds at 85. The proceeds are to be used to refund outstanding bonds and other debt, to return $302,438 to income and to pay for necessary additions and betterments. The application to the commission was noted in the ELECTRIC RAILWAY JOURNAL of July 11.

San Francisco-Oakland Terminal Railways, Oakland, Cal.—W. W. Garthwaite, member of the advisory committee in charge of the F. M. Smith interests, has been named a director in the San Francisco-Oakland Terminal Railways, to take the place of George G. Moore, who recently relinquished control of the road following his failure, through war conditions, to carry out his proposed refinancing plans.

Scioto Valley Traction Company, Columbus, Ohio.—The income statement of the Scioto Valley Traction Company for the year ended June 30, 1914, shows gross revenue of $485,696, an increase of $21,460 over the previous year. Operating expenses totaled $279,858, an increase of $18,241, caused by flood ravages and the extension of facilities for handling freight. The latter charge arose from the policy of the company to build the road out of earnings. The surplus for the year was $31,054, an increase of $2,105, the total surplus and reserves being $172,160 at the end of the fiscal year. The road carried 1,380,405 passengers during the year, in comparison with 1,332,492 in 1913. It hauled 77,146,153 lb. of freight, a gain of 12,885,907 lb., over the previous year.

Southern Traction Company of Illinois, East St. Louis, Ill.—William F. Trautman, formerly United States district attorney of eastern Illinois, was recently appointed one of the receivers for the Southern Traction Company in Illinois and the Missouri receiver for the company by Judge Francis M. Wright of the District Court in East St. Louis. Mr. Trautman was chosen to fill the vacancy made by the resignation last June of William Lorimer, Chicago.

DIVIDENDS DECLARED

Bangor Railway & Electric Company, Bangor, Maine, quarterly, one-half of 1 per cent, common.

Cape Breton Electric Company, Ltd., Sydney, N. S., 3 per cent, preferred; 3 per cent, common.

East St. Louis & Suburban Company, East St. Louis, Ill., quarterly, 1¼ per cent, preferred.

Jacksonville (Fla.) Traction Company, quarterly, 1½ per cent, preferred; quarterly, 1¾ per cent, common.

Lewiston, Augusta & Waterville Street Railway, Lewiston, Maine, quarterly, 1½ per cent, preferred.

Montreal (Que.) Tramway, quarterly, 2½ per cent.

West Penn Railways, Pittsburgh, Pa., quarterly, 1¼ per cent, preferred.

Traffic and Transportation

FARE INCREASE DENIED

Railroad Commission of California Denies Fare Increase to the Southern Pacific Company

The petition of the Southern Pacific Company to raise its one-way and monthly commutation rates between San Francisco and Alameda County points has been denied by the State Railroad Commission of California. The commission has also denied all of the other petitions that were before it affecting rates within Alameda County. Some of these petitions were brought by citizens and commercial bodies of Oakland and other Alameda County places and asked for a reduction of certain rates charged by the company. The commission orders that within twenty days the Southern Pacific Company and other interested parties present in writing to the commission their proposed schedule of rates to and from points beyond Seminary Avenue and upon the Stonehurst line, both for commutation and single fares, and it announced that unless an amicable arrangement of these issues was determined by the company on one side and residents concerned on the other, the commission would make a subsequent order with reference thereto. Those portions of the applications and complaints applying to the rates involved in that case were reserved for future determination.

The commission states that the Southern Pacific Company has been very considerate of the people of the east bay territory in the extension of its line and the extension of its $3 commutation and 10-cent single-fare rates, and expresses the opinion that it does not believe the company should be required to accord such rates to portions of the east bay cities and Alameda County other than those points to which they have been voluntarily accorded or established. It is suggested, however, that on account of the confusion which exists, it would be better for the representatives of the company, the protestants and the rate department of the commission, to arrange a uniform and proper scale of commutation and single-fare rates between San Francisco and points not now accorded the $3 monthly commutation rate and the 10-cent single-fare rate.

In its opinion the commission says in part:

"While the commission would under no circumstances suggest that improvements and substitutions, such as those brought about by the company in electrifying these lines, should be made without hope of return on the part of the agency making them, yet it is well to bear in mind that often it is necessary to build for the future; and if, as a matter of fact, the officials making the substitution were aware that under the then existing arrangement an adequate return would be made, yet under the substituted arrangement such an adequate return could only be expected after a considerable lapse of time, this fact should be considered in passing upon an application to increase rates subsequent to the change.

"We do not believe that under the circumstances under which certain suburban lines of the company were constructed in Oakland and Berkeley, this company has a right to impose upon its patrons a rate sufficient to return to it the amount which otherwise should be returned, on the ground that it has constructed facilities in excess of the necessities of the patrons. We believe the company was justified in the electrification of these lines, but are not of the opinion that it was justified in the construction of some of the added lines, except in contemplation of increased traffic in the future. Utilities are always required to have an eye to the future and they should ultimately be paid for the expenditures made.

"In the case here involved we feel no hesitancy in saying that the strictest presumptions of law should be adhered to against this company, not for the purpose of confiscating its property, but for the purpose of preventing the confiscation of tremendous values in the property of the residents of Alameda County. Thousands upon thousands of people have built their homes in these suburban communities and have paid prices for their property in contemplation of the reasonableness of these rates voluntarily accorded by this carrier. When through a long period of years a transportation company has voluntarily accorded a rate to a community on the faith of which large investments have been made, and when again the same agency has voluntarily and under no legal compulsion incurred great expenditures and largely extended its facilities, the *prima facie* reasonableness which attaches to rates which have been voluntarily accorded becomes, if not conclusive, very strongly persuasive upon any regulatory authority.

"An increase of the commutation rate alone will confiscate or take away from (the term used is immaterial) the value of the residence of every person in the territory here involved who is forced by business reasons to commute to San Francisco. Confiscation in this case looks both ways, and it does not lie in the mouth of this carrier to urge its own confiscation in utter disregard of the confiscation which it, if permitted to have its way, will have brought about among innocent people who are its patrons. Besides, we do not treat as lightly the provisions in the franchises granted by the municipalities involved as the company seems willing to do."

HEARING ON CHARLESTOWN SERVICE

The Massachusetts Public Service Commission held a hearing on Oct. 15 on the petition of the Charlestown Improvement Association for the restoration of service on the lines of the Boston Elevated Railway between Sullivan Square and Dorchester Street via Main Street, and between Sullivan Square and Pleasant Street via Bunker Hill Street. It appeared that these facilities had been withdrawn following the trial installation of a complete loop service from Sullivan Square through Main Street and Bunker Hill Street to Sullivan Square, and vice versa, the latter having been ordered by the commission several months ago in an effort to meet a demand for local service. The petitioners generally favored the restoration of the old service, which afforded opportunities for through travel in and out of Boston via the Tremont Street subway.

For the company, H. B. Potter, assistant to the second vice-president, pointed out that the original service was preferable to the present facilities and expressed the willingness of the company to restore it. The company is opposed, however, to continuing the loop service, which yielded only twenty-six circuit passengers in an eighteen-hour day, and it is opposed to offering service which enables a patron to go to City Square, Charlestown, from Sullivan Square, do a certain amount of shopping and return home for a single fare. Chairman McLeod stated that he doubted the commission's power to order the company to grant such transfers, as the road's charter only requires it to give transfers covering a ride in the same general direction. It was proposed that the loop service be retained on a thirty-minute headway, but the company's view was that a city line which would not be profitable on a twenty-minute headway or less should not be maintained. Chairman McLeod said that in establishing the Bunker Hill-Main Street service experimentally the board intended to test the application of interchange facilities found useful elsewhere on the Boston rapid transit system and recognized that the company had always opposed the loop service. The case was taken under advisement.

Metal Tickets in Lexington.—The Kentucky Traction & Terminal Company, Lexington, Ky., has begun the sale of six metal disks for 25 cents in place of paper car tickets. The disks are wrapped at the office of the company in envelopes bearing the name of the company.

Increase in Fare Sought.—Officials of the Charleston-Isle of Palms Traction Company, Charleston, S. C., have filed a petition with the Railroad Commission of South Carolina asking for permission to increase the rates from 25 to 40 cents between Charleston and the Isle of Palms.

Increase in Fares Asked.—The Augusta-Aiken Railway & Electric Corporation, Augusta, Ga., has filed a petition with the Railroad Commission of South Carolina for an increase in the rates on its line in that State from 1 cent to 2 cents a mile. A hearing on the application was set for Oct. 22.

Petition for Reduction in Fare Rejected.—The petition of Frank B. Fuller, Schofield, against the Wausau (Wis.) Street Railway, asking that a 5-cent fare be granted between Schofield and Wausau, has been dismissed by the State Railroad Commission, which declared upon investigation that the present fare is low enough.

Reducing Transfer Abuses in St. Paul.—No arrests have been made since July for violation of the ordinance passed in St. Paul in April, 1914, providing for the prosecution of persons attempting to use transfers not obtained by them on cars. The number of transfers issued by the St. Paul City Railway since the ordinance went into effect is said to have decreased materially over the same period last year.

Far Side Stop in Yonkers.—The Common Council of Yonkers, N. Y., has passed an ordinance requiring all the cars of the Yonkers Railroad to stop on the far side of crossings. The Common Council has also passed an ordinance prohibiting smoking on its cars. The company has had difficulty in enforcing the rule and the ordinance was passed to empower policemen to arrest passengers if necessary.

Recording Joy Riders.—Conductors and motormen of the Southwest Missouri Railroad, Joplin, Mo., have been supplied with cards on which they will make reports of fast or careless driving and other infractions of the traffic law by the drivers of automobiles. It is expected that these cards will be of value to the company in case of accidents in which a driver figures who has a "record" on the company's books.

Reduction in Fare on Municipal Line Rejected.—The Supervisors of San Francisco, Cal., by a vote of twelve to six, have rejected the plan to reduce the fares on the San Francisco Municipal Railway to six tickets for 25 cents or twenty-five for $1. The opinion prevailed that until the municipal system had been completed it was not good business policy to reduce the fares on the main lines, which are expected to sustain the system.

Increase in Fares on Municipal Line.—The City Councils of Port Arthur and Fort William, Ont., have approved a new schedule of fares for the municipal electric railways in the cities and on the lines connecting the two cities. The new fare is a straight 5-cent one, and the tickets are five for 25 cents. Limited tickets for workmen and school children's tickets will remain as at present. The new schedule went into effect on Oct. 1.

Baseball Traffic in Boston.—The Boston *News Bureau* of Oct. 14 said: "On Monday for forty-five minutes following the world series baseball game at Fenway Park, the Boston Elevated Railway handled 45,000 passengers, or 1000 a minute. Of course there were many thousands outside the park who were unable to gain admittance and who used the street railway. If the elevated carried to the game as many as it carried from it, the road must have handled 90,000 passengers in all—a new record in the annals of Boston street railway transportation."

"Seeing Wichita" Service.—The Wichita Railroad & Light Company, Wichita, Kan., put into service during the recent dry-farming congress a "Seeing Wichita" car which made two trips a day over the city. The charge for a trip was 25 cents for each person. The company also adorned all employees with red silk badges reading "Ask Me." The conductors especially were instructed to answer the questions of strangers so far as possible, as to the location of buildings and streets, and the badges are said to have produced a marked freedom of questioning among the passengers.

Extension of Cambridge Transfers.—The Massachusetts Public Service Commission has issued an order requiring the Boston (Mass.) Elevated Railway to extend the free transfer privileges at Central Square, Cambridge, so that passengers boarding inward-bound Western Avenue cars between Central Square and the intersection of Market Street and Western Avenue, Brighton, may transfer to cars for Pearl Street. Prior to the decision the transfer privilege was restricted to passengers boarding cars in Cambridge. Under the new arrangement complete journeys may be made for a single fare between points on two subordinate but connecting lateral lines.

St. Louis Traffic Figures for Three Months.—The quarterly report of the United Railways, St. Louis, Mo., filed with the city register, shows a falling off of about 4,000,000 in the number of passengers carried during the three months ended Sept. 30, as compared with the previous quarter. It also shows a loss of more than 2,000,000 as compared with the quarter ending Sept. 30, 1913. During the last quarter, 57,994,224 passengers were carried. During the previous quarter, 61,959,691 passengers were carried and during the quarter ending Sept. 30, 1913, a total of 81,593,938 was carried. During the last quarter, also, the number of trips made by the cars fell off about 30,000. The average number of cars operated on Sundays during the last quarter was 868; on Saturdays it was 1202 and on other week days, 1278.

Highway Accidents in New York in September.—Vehicles caused the death of seventy-two people in Greater New York during September, according to the National Highways Protective Society. Of this number forty-five were children and twenty-seven adults. Thirty-five of the children were killed by automobiles, eight by wagons and two by trolley cars. Of the twenty-seven adults killed in the city seventeen met their death by automobiles, five by wagons and five by trolleys. In New York State outside the greater city, seventy-one persons met their death by means of vehicles during September. Of these, forty-four were killed by automobiles, three by wagons, five by trolley cars and nineteen at highway railroad grade crossings. In New Jersey sixteen people were killed during September by automobiles, seven by wagons and eighteen at highway railroad grade crossings.

Connecticut Mail Suspension Order.—The Post-office Department at Washington, D. C., has modified its orders of June 23 relative to the electric car mail service, formerly performed by the Connecticut Company, so as to state the effective date of the order as June 20 instead of June 21, which was originally announced. The order discontinued the following electric railway mail routes: Hartford to South Glastonbury; Hartford to East Windsor Hill; Hartford to Wilson; Hartford to Unionville; Windsor to Rainbow; New Haven to Highwood Branch; Hartford to Station A; New Haven to West Haven Branch; Waterbury to North Woodbury; Rockville to Love Lane; Hartford to Gildersleeve; Hartford to Wethersfield; Stratford Station, Bridgeport, to Oronoque; Hartford to Newington. The statement of the company issued in connection with the discontinuance of the electric railway mail service was published in the ELECTRIC RAILWAY JOURNAL of June 27, 1914, page 1470.

Operating Figures Filed in Rochester Fare Case.—The New York State Railways has filed with the Public Service Commission of the Second District and with the corporation counsel of Rochester three sets of figures covering the cost of operating the lines of the Rochester division and the profits obtained from the lines for the years ending June 30, 1913 and 1914. The figures were compiled and submitted upon the application of Assistant Corporation Counsel Benjamin B. Cunningham, who is in charge of the interests of the city in its application to the commission for a 3-cent fare in Rochester in the rush hours of the morning and evening. The figures just filed supplement others filed recently which had to do only with the receipts in the rush hours, and the twenty-four hours for two months only. Those figures were desired by the commission for the purpose of showing what per cent of reduction was involved in the city's demand to decrease the fare in the 5-cent zone in the rush hours to 3 cents.

Public Safety Commission in Portland.—Mayor Albee, of Portland, Ore., has appointed a public safety commission for the city, with Harry P. Coffin as chairman. The commission will devote its entire attention to the prevention of accidents and the saving of human life through public education. The members of the commission are to take up various phases of public safety work. Each department head will organize the work of his section in the most effective way for carrying on the safety campaign. The commission is composed of the following gentlemen: Harry P. Coffin, chairman, in charge of traffic; B. F. Boynton, of the Portland Railway, Light & Power Company, secretary, in charge of electric transportation lines; F. L. Bruckhalter, railroad transportation lines; L. R. Alderman, schools; A. M. Churchill, Fire Chief E. F. Dowell, and Battalion Chief Stevens, fire prevention; Police Captain John T. Moore, general safety; Marshall N. Dana, industrial safety; Horace E. Thomas, publicity; Robert L. Witherol, building safety.

Personal Mention

Mr. E. D. Metcalf has resigned as vice-president and a director of the Empire United Railways, Syracuse, N. Y.

Mr. Arthur S. Pierce, formerly assistant treasurer of the Northwestern Elevated Railroad, Chicago, Ill., has been elected treasurer to succeed M. B. Van Zandt, deceased.

Mr. C. F. Hewitt, who has been assistant general manager of the United Traction Company, Albany, N. Y., has been appointed general manager, succeeding Mr. James F. Hamilton.

Mr. James P. Barnes, general manager of the Syracuse & Suburban Railroad, Syracuse, N. Y., will be appointed resident general manager of the Buffalo, Lockport & Rochester Railway, with headquarters probably in Rochester.

Mr. James F. Hamilton has resigned as general manager of the United Traction Company, Albany, N. Y., to devote all his time in the future to the Schenectady Railway, which he managed jointly with the United Traction Company.

Mr. Lee Howell, general freight agent of the Louisville & Nashville Railroad, with headquarters in Evansville, Ind., has been elected president of the Evansville Suburban & Newburg Railway, to succeed the late Frederick W. Cook.

Mr. George Theis, Jr., president of the Arkansas Valley Interurban Railway, Wichita, Kan., has been elected president of the Western Biscuit Company, Wichita, a company doing an extensive business in crackers and candy in the West.

Mr. J. G. Baukat, who was recently with the National Steel Car Company in Canada, has become connected with the Hydroelectric Power Commission of Ontario as mechanical engineer in charge of car design and the design of shops.

Mr. C. Loomis Allen will be elected vice-president of the Buffalo, Lockport & Rochester Railway, Rochester, N. Y., in charge of operation, arrangements having been made with Allen & Peck, Inc., by which that firm will take over the operation and management of the property, reporting to the president and the executive committee.

Mr. Harrison B. Riley, president of the Chicago Title & Trust Company, has been elected chairman of the executive committee and a member of the board of operation of the Chicago Surface Lines and chairman of the city railways controlling committee, succeeding Mr. Ira M. Cobe, resigned. Mr. Riley has also been elected a member of the governing committee of the Chicago Elevated Railways.

Mr. W. W. Freeman, president of the Columbia Gas & Electric Company, with headquarters in Cincinnati, Ohio, has been elected president of the Union Light, Heat & Power Company and the South Covington & Cincinnati Street Railway to succeed Mr. James C. Ernst, resigned. Mr. Polk Laffoon, secretary of the railway company, will succeed Mr. Ernst as a director in the company.

Mr. L. D. Pellisier, recently elected president of the Holyoke (Mass.) Street Railway to succeed the late William S. Loomis, was tendered a banquet at the Holyoke Club recently held by the head of the departments of the company. Mr. S. D. Nevins, secretary-treasurer of the company, presided as toastmaster. During the evening Mr. Pellisier was presented with a silver loving cup suitably inscribed as a token of esteem from the men.

Mr. George W. Anderson, of the Massachusetts Public Service Commission, has been nominated by President Wilson to the post of United States attorney for the district of Massachusetts. Mr. Anderson was born in Acworth, N. H., fifty-three years ago, was educated at Cushing Academy, Ashburnham, Mass., at Williams College and Boston University Law School. He began to practise law in Boston in 1890 and was prominent in the recent Haverhill Gas case before the Massachusetts Gas & Electric Light Commission. He was appointed to the Public Service Commission last year upon its creation and was active in the recent proceedings of the federal government in connection with the New Haven Railroad situation.

Mr. Ira M. Cobe has resigned all his Chicago connections and has gone to make his home permanently in Northport, Maine. The Chicago Surface Lines announce the resignation of Mr. Cobe as chairman of the executive committee of the surface lines, as chairman of the executive committee of the Chicago City & Connecting Railways, and as a member of the board of operation of the Chicago Surface Lines. Ill health was assigned as the cause. Mr. Cobe has tendered his resignation as member of the board of directors and executive committee of the Northwestern Elevated Railway and of the governing committee of the Chicago Elevated Railways. Mr. Cobe also has resigned from the directorate of the Chicago Title & Trust Company and it is expected that he will retire from the National Bank of the Republic.

Mr. Richard McCulloch, who has been vice-president and assistant general manager of the United Railways, St. Louis, Mo., has been appointed general manager in addition to vice-president to succeed his father, the late Capt. Robert McCulloch, but no successor has been elected to Captain McCulloch as president of the company. Mr. Richard McCulloch was born in St. Louis in 1869 and was graduated from Washington University in 1891. He engaged in mining and later became connected with the Cass Avenue & Fair Grounds Railway, St. Louis, and subsequently with the consolidated system. After several years spent in railway work in Europe Mr. McCulloch returned to the United States to accept a position under his father with the Chicago City Railway. When Captain McCulloch was appointed to the United Railways his son entered that company under him as assistant general manager.

OBITUARY

Isaac Ellsworth, one of the pioneers in street railway work in Milwaukee, Wis., is dead. He was eighty-two years old. Mr. Ellsworth was born in Ulster County, N. Y., and entered business in Milwaukee in 1856. In 1869 he and George F. Lynch purchased the property of the Milwaukee City Railway, with which he continued actively for many years.

M. J. Kenney, superintendent of the lighting department of the Little Rock Railway & Electric Company, Little Rock, Ark., is dead. Mr. Kenney was born in Elizabeth, N. J., and for the last fourteen years was continuously in the service of the Little Rock Railway & Electric Company. He is survived by a widow and daughter.

Stuart Richardson, who held the position of tramways engineer to the Wellington (N. Z.) City Corporation, died on Sept. 11 after a brief illness. Mr. Richardson was born at Swansea, England, on Jan. 9, 1863. He obtained his training as an electrical engineer with the Brush Company at Loughborough. After severing his connection with that company he entered the service of the Leicester Corporation and subsequently was appointed to the position of city electrical engineer, in which capacity he continued until he left for New Zealand to take up the management of the New Zealand Electrical Syndicate, which then controlled the electric lighting of the city of Wellington. On the termination of his engagement with this company Mr. Richardson entered the service of the tramway department of the Wellington Corporation and in 1905 was appointed tramway and electrical engineer, continuing in that position until his death.

John Lewis Matson, president of the Chicago & Interurban Traction Company and vice-president of the Hammond, Whiting & East Chicago Railway, died at his home in Chicago on Oct. 18, following an operation. Mr. Matson was forty-six years of age. He was born in Gottenborg, Sweden. He entered railway work as an apprentice in the general repair shops of the Illinois Central Railroad in Chicago, and in 1893 he was made assistant master mechanic of the South Side Elevated Railroad of Chicago. In 1902 he became superintendent of motive power of the Indiana Union Traction, and in 1905 resigned from the company to become superintendent of motive power of the Chicago & Milwaukee Electric Railroad. In 1906 he became associated with A. L. Drum & Company, and in 1907 was made manager of the South Chicago Street Railway, which was later consolidated with the Calumet Electric Street Railway, and now forms the Calumet & South Chicago Railway. In September, 1910, he was also elected vice-president of the Hammond, Whiting & East Chicago Railway. He was subsequently elected president of the Chicago & Interurban Traction, which operates between Chicago and Kankakee, Ill. Mr. Matson is survived by his widow.

Construction News

Construction News Notes are classified under each heading alphabetically by States.

An asterisk (*) indicates a project not previously reported.

FRANCHISES

Benicia, Cal.—A. D. Bowen, representing the Benicia Land & Terminal Company, has received a franchise from the Council in Benicia. This is a part of a plan to build an electric line between Benicia and Vallejo. [E. R. J., Oct. 12, '14.]

Los Angeles, Cal.—The Los Angeles Railway Corporation has asked the Council for a franchise for a double-track line as an extension of the East First Street line into the Huntington hills, east of Boyle Heights.

***Los Angeles, Cal.**—The Glen Alta Improvement Association has asked the Council for a franchise to build an electric railway from the intersection of North Broadway and Pritchard Street to Hermon Street. Robert T. Hale and F. J. Whiffen are interested.

San Lorenzo, Cal.—The San Francisco-Oakland Terminal Railways has received a franchise from the Council to extend its railway in San Lorenzo in a straight line from the cemetery to the terminus.

***Lewiston, Idaho.**—R. C. Dahlheim and associates will ask the Council for a franchise to build an electric line in Lewiston. Application will also be made at once to the Council in Clarkston to build an electric line in Clarkston. This is part of a plan to build an electric railway to connect Lewiston and Clarkston.

Pocatello, Idaho.—J. D. Browning, representing the Pocatello Traction Company, has received a franchise from the Council in Pocatello. The terms of the franchise call for the construction of 1½ miles of track the first year and the same amount of mileage in each of the following years. [E. R. J., Sept. 5, '14.]

Springfield, Ill.—The Lee County Electric Railway has filed with the Illinois Public Utilities Commission an application for a certificate of convenience and necessity to construct a line from its present terminus in Bradford, Ill., northeasterly to Rochelle and from a point of connection with the present line, thence northerly to Ashton. The company is also petitioning for authority to issue stock for the acquisition of property and for the construction, extension and improvement of its facilities.

New Orleans, La.—The Orleans-Kenner Electric Railway has asked the Council for a franchise for a line from the upper Protection Levee to the center of the business district in University Place in New Orleans. This 110-mile line will connect New Orleans, Hanson City, Harriban and Shrewsbury. J. A. Bowman, New Orleans, president. [E. R. J., July 18, '14.]

Amherst, Mass.—The Holyoke Street Railway has asked the Council for a franchise in South Amherst near Potwinlane.

St. Peter, Minn.—The Electric Short Line Railway has asked the Council for a franchise in St. Peter.

Orange, N. J.—The Public Service Railway has asked the Council for a franchise for the extension of the Central Avenue line through Orange to the Morris Street terminus of the Crosstown line.

Tonawanda, N. Y.—The International Railway and the city authorities have reached an agreement on the franchise to be granted the company to operate an electric line through Tonawanda over the right-of-way of the Frontier Electric Railway. In return for permission to operate the new line the International Railway will grant the city a 5-cent fare to Elmlawn Cemetery and restore the ticket system on the Kenmore line.

Wilmington, N. C.—The Wilmington-Carolina Beach Railway has received a franchise from the Council in Wilmington. This proposed 10-mile line will connect Wilmington and the Carolina Beaches. C. C. Chadbourne, Wilmington, president. [E. R. J., Aug. 22, '14.]

Cornwall, Ont.—The ratepayers of Cornwall have voted in favor of a by-law to grant the Cornwall Street Railway, Light & Power Company a twenty-year extension of time on its franchise in Cornwall.

Portland, Ore.—The Portland & Oregon City Electric Railway will retain its recently secured franchise as granted by the City Council. The attempts of Commissioner Brewster to have the action of the Council rescinded have failed.

***Harrisburg, Pa.**—The Perkiomen Electric Transit Company has asked the Public Service Commission for a certificate of public convenience to build a 40-mile trackless trolley line along the public highway from Phoenixville to Emaus. James L. Wolcott, Dover, Del., president.

Nashville, Tenn.—The Nashville Traction Company has asked the Council for a franchise from the end of its Fifth Avenue line, at the corner of Mulberry Street and Fifth Avenue, across to Second Avenue and thence to Lafayette Street, there to connect with the line that has been built to the city limits at the junction of the Murfreesboro Pike and the Tennessee Central Railroad in Nashville. [E. R. J., Oct. 12, '14.]

Snohomish, Wash.—The Puget Sound Electric Railway has received a franchise from the Council to extend its lines to the main street in Snohomish. The franchise allows the company to terminate its line at Union Avenue and First Street, reaching this point by way of Fifth Street, Maple Street and Fourth Street, thence west on Fourth Street to Cedar Street and down Second Street to Union and First Street in Snohomish.

TRACK AND ROADWAY

***Decatur, Ala.**—Plans are being contemplated to build an electric line to connect Decatur, Huntsville, Athens and Florence. Humphrey Read, Florence, is interested.

Hot Springs (Ark.) Street Railway.—Plans are being made by this company to extend its line to the golf club in Hot Springs. Through the efforts of Simon Cooper, Ernest Latta and W. O. Forbes, arrangements have been made with the local banks for the advancement of the necessary funds to build this extension. The general officers of the Public Utilities Company have been willing to make the improvement, but on account of the trouble at this time in securing capital found it difficult. With this arrangement made the work will be taken up at once in order to have the extension in operation by the opening of the season.

Sacramento Valley Electric Railway, Willows, Cal.—This company has placed in operation the first 12-mile unit of its railway which connects Dixon and Dixon Junction. Ultimately this line will be extended to Woodland, Willows, Corning and Red Bluff.

San Francisco, Cal.—Applications have been filed with the Board of Supervisors for the construction of twenty-eight branches of the Municipal Railway in San Francisco. These are in addition to the line for which a $3,000,000 bond was issued some months ago.

Sausalito, Cal.—The Marin County Electric Railways has asked the Railroad Commission for a certificate of public convenience and necessity to build an electric railway in Sausalito; to issue 150 shares of capital stock of a par value of $150,000, and permission to begin work on private funds during the time the sale of the stock is pending. [E. R. J., Oct. 12, '14.]

***Peoria, Ill.**—Estimates and preliminary surveys are being made to build an electric railway to connect Peoria and Washington, in Tazewell County. A. Black, Peoria, and W. H. Shott, Chicago, are interested.

Bloomington & Normal Street Railway, Bloomington, Ill.—M. G. Linn, superintendent of this company, states that grading and laying of new rails is contemplated preparatory to the pavement of Clinton Street between Emerson and Division Streets in Bloomington. It is the intention of the company to have the track in proper shape when the paving work is done.

Kankakee & Urbana Traction Company, Urbana, Ill.—This company is now laying 5 miles of new track between Rantoul and Ludlow. Cars will be running between Rantoul and Ludlow by Nov. 10. It is the intention of this company to build 5 miles of track next spring between Ludlow and Paxton, making in all 25 miles of track between Urbana and Paxton.

Waukegan, Fox Lake & Western Railway, Waukegan, Ill.—Plans are being considered by this company to double-track its line along Washington Street in Waukegan.

Des Moines (Ia.) City Railway.—Improvements are being planned by this company for its Center Street line in Des Moines. The line will be double-tracked as far as Twentieth Street and Clark Street.

Union Traction Company, Anderson, Ind.—Plans are being made by this company to build at once a new bridge over Greens Branch at Sixteenth Street in Anderson.

***Covington, Ind.**—The destruction by fire of a wooden bridge at Covington may delay the building of an interurban line from Danville, Ill., to Crawfordsville, Ind., intended to unite the Illinois Traction System with the network of Indiana and Ohio lines and to provide through service from St. Louis to Indianapolis, Louisville, Columbus, Cincinnati and many other points. It seems that one of the stumbling blocks in the construction of an interurban line from Danville to Crawfordsville was the expense of bridging the Wabash River. It is said that the Illinois Traction System has options on a right-of-way between Danville and Crawfordsville and that the company is to meet the officials of Warren and Fountain Counties and discuss what can be done in the way of a bridge to be mutually owned, the expense of construction being defrayed by the counties which are concerned and the company or companies involved.

Arkansas Valley Interurban Railway, Wichita, Kan.—A contract has been agreed upon by this company and the Hutchinson Street Railway for a connection giving the Arkansas Valley Interurban Railway an entry into Hutchinson. The Hutchinson Street Railway will be extended east 1 mile from the Larabee mill along what will be an extension of Avenue B, to the next section line 1 mile east, Halstead Avenue, south of the strawboard works. At this point the Arkansas Valley Interurban Railway will connect with the Hutchinson Street Railway coming in from Halstead and Burrton along the Santa Fé Railway.

New Orleans Railway & Light Company, New Orleans, La.—This company is asked to consider plans to build a new line from Poland Avenue in the Seventh Ward in New Orleans.

Boston (Mass.) Elevated Railway.—This company is asked to consider plans to extend its tracks in Boston from Summer Street over the viaduct to the Commonwealth fish piers, to Northern Avenue and on Northern to Atlantic Avenue.

Fitchburg & Leominster Street Railway, Fitchburg, Mass.—This company is asked to consider plans to extend its tracks to the fair grounds in Fitchburg.

Union Street Railway, New Bedford, Mass.—Plans are being made by this company to extend several of its lines in New Bedford. One proposition is to extend the tracks in Kempton Street from Summer Street east to Purchase Street.

Berkshire Street Railway, Pittsfield, Mass.—The extension from Blandford to Huntington, making a through line from East Lee, has been completed by this company and will soon be placed in operation.

Detroit (Mich.) United Railway.—This company is asked to consider plans to extend its Kercheval line to Connor's Creek Avenue in Detroit.

Mesaba Railway, Virginia, Minn.—Plans are under way by this company for an extension to Aurora. Work will be begun in the spring.

***Kansas City, Mo.**—Taking advantage of a special provision in the new electric railway franchise, the property owners in the Seventy-fifth Street district to be benefited have subscribed the money with which to build an electric line along Seventy-fifth Street from the state line to Broadway, where connection will be made with the Dodson extension of the Metropolitan Street Railway. Under the provisions of the franchise, the new line will be turned over to the Metropolitan Street Railway to operate under a lease for use of the tracks.

United Railways, St. Louis, Mo.—Plans are being considered by this company to build a line between Wellston and Lindenwood.

St. John (N. B.) Street Railway.—Work has been begun by this company on the extension to Marsh Road in St. John.

Westchester Electric Railroad, Mount Vernon, N. Y.—This company is considering the extension of its Mount Vernon-North Pelham line from its present terminal in North Pelham to the New York Central & Hudson River Railroad station in Tuckahoe. The route would lead along the public highways of Pelham and East Chester for about 2 miles.

New Castle Electric Street Railway, Youngstown, Ohio.—Plans are being made by this company to build more than 5 miles of extensions in New Castle.

Brantford (Ont.) Street Railway.—Work has been begun by this company on improvements to its lines in the east ward in Brantford.

***Guelph, Ont.**—Surveys are being made to build a hydro-electric radial railway between Guelph and Toronto, eventually to proceed through western Ontario.

Peterborough (Ont.) Radial Railway.—Work has been begun by this company on the construction of a branch in Peterborough to connect with the lines of the Canadian Pacific Railroad.

Toronto Suburban Street Railway, Toronto Junction, Ont.—The 12-mile extension to Woodbridge has been placed in operation by this company.

Nashville (Tenn.) Traction Company.—Construction work on the Shelby Avenue line in Nashville is progressing at the rate of one block a day, all necessary materials and equipment being on hand.

Nueces Valley, Rio Grande & Gulf Railroad, Belleville, Tex.—The 25-mile railway from Kitty along the Nueces River to Simmons and Live Oaks will be operated by steam and not by electricity. W. A. Malthaei, Belleville, president. [E. R. J., Nov. 15, '13.]

Dallas (Tex.) Consolidated Electric Railway.—The final contract has been signed for the extension of this line to the Southern Methodist University, and the Stone & Webster Engineering Corporation will begin work at once.

Houston (Tex.) Electric Railway.—Plans are being made by this company to double-track its line on Fannin Street and on Travis Street in Houston.

McKinney, Bonham & Paris Interurban Railway, McKinney, Tex.—Right-of-way is being obtained by this company in the vicinity of Brookston. A new line will be located from Honey Grove to Paris. L. A. Scott, president. [E. R. J., Oct. 3, '14.]

Salt Lake & Utah Railroad, Salt Lake City, Utah.—This company is extending its tracks on Academy Avenue from First North Street to Eighth North Street in Provo. It is the intention of the company to place in operation at once its lines now laid in Provo.

Gray's Harbor Railway & Light Company, Aberdeen, Wash.—It is reported that this company contemplates the extension of its tracks into North Aberdeen as far as Fernhill Cemetery. This could be done by extending a branch from the "B" Street line down Second Street and over the North Aberdeen Bridge or by connecting with the East Aberdeen line.

Tacoma, Wash.—The first definite steps toward the construction by the city of Tacoma of the tideflats line, for which $35,000 worth of utility bonds were ordered issued to the local banks recently, were taken when Commissioner Owen Woods closed the contract with the United States Steel Company for the purchase of 152 gross tons of steel rails. The rails will arrive this month, and the work of laying them will begin at once. The first bid calls for 118 gross tons of 70-lb. standard section Bessemer "T" rails. Another order includes 14 gross tone of "T" rails, in 30-ft. lengths. Talk of extending the tideflats line to the city limits at Sitcum Avenue, and the annexation soon by the city of the tideflats to the Bluffs, and the construction of the line to the east shore of the Bay, is being considered by the City Council. Mayor Fawcett indorses the proposition.

Princeton (W. Va.) Power Company.—Work has been begun by this company at the Princeton end of this company's proposed 12-mile electric railway between Princeton and Bluefield. [E. R. J., May 17, '14.]

Wisconsin-Minnesota Light & Power Company, Eau Claire, Wis.—This company will award contracts to build its 1-mile extension to Mount Tom in the spring of 1915.

SHOPS AND BUILDINGS

Carmack Railway & Power Company, Opelika, Ala.—Plans are being considered by this company to build its new carhouse and repair shops at Opelika. Fulton Pace, Opelika, chief engineer. [E. R. J., Oct. 3, '14.]

Des Moines (Ia.) Railway.—Plans are being considered by this company to build a new carhouse and repair shop on the river bank, at the present site of the interurban terminal in Des Moines.

New Orleans Railway & Light Company, New Orleans, La.—A new passenger station is being contemplated by this company on New Basin Canal at West End in New Orleans.

Worcester Consolidated Street Railway, Worcester, Mass.—Land has been leased by this company just west of Main Street, near the junction of Sterling Street and Main Street in Clinton on which the company has just built a new freight house. Plans are being considered by this company and the Fitchburg & Leominster Street Railway to build a union freight house in Leominster to be used by both the companies.

Niagara Gorge Railroad, Niagara Falls, N. Y.—This company has awarded a contract to the Turner Company, Buffalo, to build its new carhouse, repair and paint shop. The structure will be 156 ft. x 200 ft. and of tile and reinforced concrete construction.

Cincinnati (Ohio) Traction Company.—Plans are being considered by this company for the construction of a new building to be used as an interurban passenger station and which will provide for convention hall facilities on the second floor. It is contemplated to construct this building on the site of the old hospital in Cincinnati.

Chattanooga (Tenn.) Traction Company.—This company is soon to open a new station on its line at Crystal City, the name given to the new resort being constructed at the foot of Signal Mountain. This improvement is well under way, construction work on the 12-acre lake, for which extensive excavations were made, having been completed and work on the concrete spillway of the dam has begun.

Texas Traction Company, Dallas, Tex.—Work has been begun by this company on the new freight house for the new interurban depot which is being built in McKinney. The structure will be 40 ft. x 40 ft. and of brick construction. The passenger station will be erected at a later date in addition to this new building.

Ogden (Utah) Rapid Transit Company.—This company has awarded a contract to C. F. Dinsmore, Ogden, to build its new interurban passenger station on Twenty-fourth Street in Ogden. The structure will be 50 ft. x 270 ft. The cost is estimated to be about $25,000.

POWER HOUSES AND SUBSTATIONS

Carmack Railway & Power Company, Opelika, Ala.—Plans are being made by this company to build a new power plant at Lake Carmack. H. A. Bedell, Opelika, president. [E. R. J., Oct. 3, '14.]

Fort Dodge, Des Moines & Southern Railroad, Des Moines, Ia.—Improvements and additions to cost more than $50,000 will be made on this company's power plant at Fraser.

Topeka (Kan.) Railway.—A. M. Patten, manager of this company, denied recently in an interview that the company was arranging to equip its old Second Street power house to supply itself with power. The report intimated that if the plant was so equipped the Edison Company would sell its equipment to the city. Mr. Patten said that the railway company was planning to use the Second Street building as a repair shop.

Holyoke (Mass.) Street Railway.—This company is now building its new power house in Mill Valley to be used for the Amherst and Suderland division.

Brantford (Ont.) Railway.—This company has purchased a Westinghouse 200-kw, twenty-five-cycle rotary for its power house in Brantford.

Manufactures and Supplies

ROLLING STOCK

Stroudsburg (Pa.) Passenger Railway has ordered one car body from The J. G. Brill Company.

Spokane, Portland & Seattle Railway, Portland, Ore., has ordered one 70-ft. gas-electric car from the General Electric Company.

Centralia & Central City Traction Company, Centralia, Ill., expects to purchase one pair of car trucks and two G. E. 54-A motors.

Charleston (W. Va.) Traction Company has ordered twelve double-truck city and suburban cars from the Cincinnati Car Company.

Danville (Va.) Traction & Power Company, noted in the ELECTRIC RAILWAY JOURNAL of Oct. 17 as having ordered two double truck pay-as-you-enter cars from the Southern Car Company, has specified that these cars will be built of T-iron construction, arched roof, St. Louis seats, Railway Utility Company's ventilators, Agasote ceiling and mahogany finish.

Brantford (Ont.) Municipal Railway has ordered six single-truck pay-as-you-enter cars from the Preston Car & Coach Company for delivery at the end of this year. The cars have steel underframes and are mounted on Taylor extra-heavy single trucks having an 8-ft. wheelbase. The cars are equipped with Westinghouse 101-B2 motors, K-10 controllers, Nuttall trolley bases, two Keystone illuminated signs per car, and Cleveland fare boxes.

Boston (Mass.) Elevated Railway, noted in the ELECTRIC RAILWAY JOURNAL of Oct. 17, 1914, as planning to send out this week specifications for a large number of trail cars, is in the market for from fifty to 100 trail cars for probable early use in the Boylston Street subway. The details of these cars have not yet been fully settled, but they will be of the center-entrance, prepayment type, weighing about 30,000 lb. each, and equipped with double trucks and a low step. The cars will be designed to operate in trains with the present No. 4 semi-convertible prepayment motor cars used on various subway and trunk lines.

TRADE NOTES

Walpole Tire & Rubber Company, Walpole, Mass., has appointed I. W. Penniman as Western sales manager. Mr. Penniman has charge of the Chicago office, located in the Brooks Building.

Ohmer Fare Register Company, Dayton, Ohio, on Oct. 7 distributed a large number of prizes among its employees for the best suggestions made during the past six months in regard to improvements in manufacture and for the welfare of its employees.

G. D. Peters & Company, Ltd., London, England, European correspondents of the Hale & Kilburn Company, announce that they supplied the seating material for the cars of the Constantinople (Turkey) Tramway, an article on which appeared in the Aug. 1, 1914, issue of the ELECTRIC RAILWAY JOURNAL.

E. E. Brownell, Philadelphia, consulting engineer, has been retained by the Memphis (Tenn.) Street Railway for about four years to supervise the installment of a mitigation system to prevent electrolysis of the water mains and pipes. The cost of the original installation will be approximately $1500, the railway company bearing the expense.

Independent Pneumatic Tool Company, Chicago, manufacturer of Thor pneumatic tools and electric drills, has appointed W. W. Robinson its representative in Michigan with headquarters at Detroit. F. J. Passino, the Michigan representative of the company, has been appointed to represent the company in the Southwest to succeed H. F. Finney, promoted to a position in the general sales office in Chicago.

Van Dorn & Dutton Company, Cleveland, Ohio, at a special meeting of its board of directors on Oct. 2, appointed H. H. Hodell, president of the Cleveland Galvanizing Works Company, and interested in several Cleveland enterprises, one of the founders of this company and for many years its vice-president, as president to succeed the late James H. Van Dorn. T. B. Van Dorn, now president of the Van Dorn Iron Works, Company, Cleveland, Ohio, was appointed vice-president to succeed Mr. Hodell. The active conduct of the company's affairs continues under the direction of F. W. Sinram, secretary and treasurer, and Franklin Schneider, manager and chief engineer.

Electric Service Supplies Company, Philadelphia, has been appointed exclusive selling agent of "Never Creep" anchors, manufactured by the Chance Manufacturing Company. These anchors are installed by boring a hole (preferably with an auger) at as near right angles to the line of strain as conditions will allow. The anchor rod is then forced down through solid earth, by driving, stopping the head of the rod about the center of the hole. After the anchor rod is installed, it is only necessary to lower the anchor plate into the hole, by means of a special tamping bar, engaging socket in plate with head of rod. The rod is then pulled up on and the anchor is ready for service. The anchoring of the rod in undisturbed earth renders impossible creeping of the anchor.

ADVERTISING LITERATURE

Transmission Engineering Company, Pittsburgh, Pa., has issued a folder which contains illustrations of installations of its steel work for electrical requirements.

Lutz-Webster Engineering Company, Inc., Philadelphia, has issued Bulletin No. 4 which outlines the details of a prize contest which this company has offered to all mechanics, involving eighteen cash prizes, ranging from $100 to $5, for the best reports bringing out the points of highest merit of the tools manufactured by the company.

Speer Carbon Company, St. Mary's Pa., has just issued a remarkably extensive book on carbon brushes under the designation of "Price List No. 7." The publication, however, not only contains such tabular matter as is necessary for ordering brushes, but also a great deal of data about the experiments which this company has made to perfect brushes for different kinds of service. Special attention is given to brushes for railway service including compressors. The tables show the brushes required for the oldest types of motors as well as for the latest commutating pole designs. The most instructive feature is the series of load curves which accompany the reference to each kind of brush.

Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa., has issued a special catalog, No. 1552, outlining in general the progress which this company has made during the last year. The catalog contains brief and characteristic descriptions, accompanied by photographs, of electrical installations recently made on the following electric railways: Pennsylvania Railroad, Norfolk & Western Railway, New York, New Haven & Hartford Railroad, Long Island Railroad, New York Municipal Railway, Chicago Elevated Railways, Boston Elevated Railway, Niagara Junction Railway, Waterloo, Cedar Falls & Northern Railway, Sand Springs Railway, Connecticut Company, Youngstown & Ohio River Railroad, Lewisburg & Ronceverte Electric Railway, Salt Lake & Utah Railroad, Ogden Rapid Transit Company, Michigan United Traction Company, Oakland, Antioch & Eastern Railway, Kansas City, Clay County & St. Joseph Railway, Grand Rapids, Holland & Chicago Railway, Ohio Electric Railway, Northern Ohio Traction & Light Company, Wilkes-Barre Railway, Jersey Central Traction Company, Third Avenue Railway, Manhattan Bridge Three-Cent Fare Line, Municipal Railway of San Francisco, Cleveland (Ohio) Railway, Colorado Railway & Light Company, Northern Texas Traction Company, Public Service Railway, Charlotte (N. C.) Electric Company, Rio de Janeiro Tramway, Light & Power Company, Toledo, Fostoria & Findlay Railway, Omaha & Council Bluffs Street Railway, Panama Tramways, St. Paul Southern Electric Railway and Jamestown, Westfield & Northwestern Railway. Another special publication No. 1549 contains a number of interesting illustrations showing operating conditions in traffic centers of about thirty large American cities. Circular No. 1550 gives a detailed illustrated description of recent installations of this company's 1500-volt d.c. substation equipment. Circular No. 1546 contains a collection of illustrations, with brief notes, showing some of the advantages of multiple-unit trains.

MAINTENANCE OF TRACK DRAINS

Last week we discussed the report of the way committee, particularly its recommendations of drainage systems, but did not take up the question of the maintenance of these systems. The usual form of construction is the ordinary farm drain tile with butt joints, laid in the natural soil. If care is exercised in laying this tile to a uniform line and grade and sufficient fall is provided so that the tile becomes self-cleaning, it will not need further attention. But where these precautions have not been taken, the drainage system soon becomes valueless because it becomes clogged with silt. It must then be dug up and cleaned or else abandoned. The 1914 way committee provided against obstructed drains to a certain extent by recommending a filter area surrounding the tile. The character of tile used is also important. Some engineers employ a No. 2 grade vitrified bell and spigot tile in place of the ordinary clay drain tile. No attempt is made to seal the bell and spigot joints, but a cinder filter medium surrounds each joint. The fact that the flow line of the pipe is vitrified and smoother than with the ordinary porous clay tile helps such a drain to be self-cleaning on a slighter grade than would otherwise be the case. Attention is called to these points because they are of importance if there is any weight to the argument for drainage systems in paved streets, and we believe that there is.

EMPHASIZING LOCAL EXPENDITURES

Occasions frequently arise in railway operation where it is to the advantage of the company to set forth for the consideration of local communities amounts of money expended in new construction or maintenance within their limits during a stated period. The fundamental economic principles will bear a good deal of illustration in moderately populated places served by a progressive system. The amount of money which finds its way back to the people in connection with the replacement of ties, the feeding of construction gangs, patronage of local hardware and livery concerns, employment of carpenters from nearby villages, etc., is but little realized by the general public. On many lines a large percentage of the ties used may be produced along the lines of the road, benefiting farmers, owners of small woodlots, and local lumber companies. The proportion of native ties varies widely with the locality, but even where this is low it does not take long to discover that month by month a good deal of money is expended by transportation lines in the communities traversed by them. Every such agency bringing new and alert people into small towns is a stimulating influence and a constructive force in daily life. It may not pay to segregate minutely disbursements in small communities, but positive statements as to genuine cash outlays for equipment, labor and supplies furnish excellent material with which to combat the opinion that the company merely seeks to exploit a given neighborhood. It is almost always a case of give and take for value received, and the opportunity to bring this out with concrete examples is worth cultivating.

NATIONAL SOCIETIES GETTING TOGETHER

As this issue of the Electric Railway Journal is being mailed to our readers a meeting of technical society secretaries is being held in New York for the purpose of forming a society of such secretaries. This is the outgrowth of a movement begun about a year ago among the steam railroad associations. A similar movement has been on foot among the technical societies. The organization of the electric railway associations is such that co-operation among themselves is provided for by their constitutions. All of these efforts toward co-operation will now be combined, and an organization will undoubtedly be perfected that will mean much to all of the contributing societies. The first work will presumably be in the direction of rationalizing convention dates and locations. Something should be done in this line, for the array of conventions which the progressive railway or professional engineer is expected to attend is appalling, and they are held with little regard to economy of time, money and energy of the attendants. If the new association is successful in the first effort a still larger field for co-operation in activities will be opened up, and plans for minimizing duplication of effort can be laid. There have been many illustrations of the difficulties arising when two or more societies try to cover the same ground for practically the same purpose. Again there is a constant multiplication of organizations as the work of engineering, design and operation becomes more highly specialized. In some cases this is partly due to the ambitions of the organizers who wish to see their specialties receive public recognition. It will be a splendid achievement when all of our national societies are working in harmony. It is possible that when the millennium arrives means can be devised to reduce to a more rational size the number of societies which now apparently seem necessary.

THE CODE OF PRINCIPLES

At the Atlantic City convention a code of principles was adopted, and the question may be asked: "Why is any code necessary?" In reply, let us say first that the decision to have such a code was not snap judgment on the part of the association. It had been under serious consideration for at least two years, and the action at Atlantic City was simply the consummation of this plan. The principles, as adopted, are printed in the supplement which accompanies this issue.

The purpose of any code of this character is twofold: it should crystallize sentiment and thought both outside and inside the interest affected. In the case of the electric railway industry it will help the outside public to understand concretely the attitude of the companies. It will also assist railway companies themselves better to understand their own problems. There is nothing so helpful to clear thinking as to state one's ideas definitely in black and white.

The code as formulated contains an epitome of the problems confronting the industry at the present time and likely to confront it for years to come. It gives in tabloid form the substance of a great many published papers and addresses presented at meetings of electric railway associations. It helps to define the issues which are now before the electric railway companies, both in their own minds and in the minds of the public. The drafting of the code constitutes an important step in producing a better understanding between the company and the public. The next step is to convert the principles there expressed into vital energy by using them to the best advantage.

To do this every thinking individual connected with the electric railway industry should study the principles carefully, particularly as they affect his own surroundings. He should also test them by his own practical problems so that he will be familiar with them and their application. If the public utility men of the country do not understand just what the statements in the code mean and are not convinced of their correctness or fairness, they can hardly expect the public to understand and accept them.

Having studied the principles of the code carefully each company should bring it to the attention of its own public, especially to the thinking portion of its public. The association has a comprehensive plan for doing this on a large scale, but each member of the association can begin the work on a smaller scale in his own community. We suggest that this should be done at once and that the public relations committee be kept informed of the progress made in the various electric railway centers. A passive acceptance of the code will be of little service to anyone. It must be understood, used and pushed if it is to be of value to the industry.

In studying the principles of the code it is very important to associate the numbers with the respective principles, just as we do in the case of the amendments to our federal Constitution. This will give "handles" by which the principles can be promptly grasped when needed, but to make effective the use of such "handles" the numbers and the principles must be firmly tied together in the minds of the members of the electric railway profession.

CLAIM AGENTS AND THE PUBLIC

To our minds the most striking points in the claim agents' papers and the discussions at Atlantic City, published elsewhere in this issue, are those in connection with psychology in claims work, publicity of claim department work and education as an injuries and claims preventive. Every successful claim agent, whether he knows it or not, bases his work upon psychological principles, but success is more certain and more rapidly attained if he is consciously carrying out the psychological precepts outlined by Mr. Rice. We are particularly interested in Mr. Rice's recognition of the value of prohibiting a negative idea in the claimant's mind by injecting a positive idea. This procedure is directly in accord with the most advanced school of modern salesmanship, which lays great stress not upon the removal but upon the anticipation and the actual prevention of all inhibitions in the buyer's mind. This simply means blocking the other man's objections before he himself conceives them, and it offers a profitable field of study to claim agents.

The amount of publicity that should be given to claim department work is a disputed question, but we are inclined to believe that the good results obtained from jurors and judges being made to understand the cost of claims, the number of claims settled out of court, and the prevalence and ingenuity of fakirs' claims would overbalance the bad results accruing on account of the suggestive "playing up" of such stories to embryo malingerers and crooked claimants. The vital point is, of course, that the sensational newspaper, as the disseminator of such information, has a greater effect upon the undesired class. For this reason the question seems to go back to the fundamental advertising principle of choosing the proper medium. Here the claim department can help not only by using a judicious follow-up system to prove to past jurors the deception of claimants, but also by endeavoring to see that the mediums best suited to the responsible citizens of the city are furnished with an explicit, frank and truthful account of fakirs' activities. As regards claim department methods in circumventing fakirs, however, general publicity of such matters is comparatively as undesirable as the complete disclosure of secret service and diplomatic practices and is recommended by neither theory nor practice.

In general, the kind of publicity that the claim department needs, and can be benefited by, is the publicity that comes from proper operating equipment and treatment of passengers and from education of the public along the line of preventive methods. The "safety first" movement of to-day has placed the accident prevention and settlement work of electric railways in such a new and more favorable light that sight is being lost, to a considerable extent, of the word "claim" with its inevitable association of lawsuits and their resultant crop of bitter feelings. Instead emphasis is being laid in the work of the claim department upon "safety bureau" and "safety agent," with their clear accentuation of the humanitarian rather than the litigious side of the accident prevention department. This is a distinct step in advance and one of which full advantage should be taken.

This suggests that while no definite rule can be laid down for claim department publicity, it is not too utopian to believe that in safety education alone may lie the solution of the problem. Moreover, it may be the most efficacious method of creating in the individual a proper appreciation of the railways' interest in and efforts for the riding public.

THE 167 PER CENT CAR

The extraordinary rehabilitation of some 1600 cars on the Brooklyn Rapid Transit System, as described elsewhere in this issue, is a triumph of consistent maintenance. These cars have seen service anywhere from nine to seventeen years, yet their useful mileage has been climbing constantly from year to year as improvement after improvement reduced the shop time caused by defects of equipment. The standardization program of the Brooklyn surface rolling stock, begun in January, 1904, and completed in July, 1909, was the first and largest task of the kind ever undertaken. It was this program that raised the daily mileage per car during the period from 1908 to 1913 by permitting a uniform period of 600 miles between inspections. Even this record is to be surpassed by raising the period between inspections to 1000 miles—an extension made possible by the installation of air and geared brakes, automatic slack adjusters and pneumatic sanders under every car weighing more than 25,000 lb. In view of these circumstances it seems fitting to refer to the efficiency rating of the rehabilitated rolling stock not as 100 per cent but as 167 per cent. More than $1,000,000 has already been spent for the 1600 cars described, and another $176,000 has been authorized for similar improvements to 800 open cars.

That the car bodies must have been maintained in excellent condition during the past decade is clear from the fact that they were capable of an underframe reconstruction that left little more than the side and end sills in their original positions. The extra weight of the new equipment naturally made reinforcement of the underframe a necessity, and by carrying matters a little further the mechanical department also attained a uniform layout for each of the great car groups described in the article. It is certainly creditable to both the car builders and operators that these cars could be rebuilt, say, for an extra weight of 2000 lb., and still return to the line fit for harder service than ever.

To one not in close touch with the transportation problems of the Brooklyn Rapid Transit System it might have seemed the wiser policy to have replaced at this juncture the older part of the present rolling stock. But in view of the practical impossibility of foreseeing how greatly the vast rapid transit system now under way will cut into or readjust the surface traffic, it was surely better to spend $620 per car than more than ten times that amount per car for new rolling stock.

WHY NOT INVESTIGATE STANDARDS IN CAR DESIGN?

In last week's issue a correspondent has suggested the formation of a committee composed of representatives of the car builders and the railways for the purpose of standardizing, in so far as possible, the design of electric railway cars. The idea is unquestionably an excellent one for producing results. The electric railways of the country, thanks to the work of the American Electric Railway Association, form a more closely-knit organization than will be found in any other similar industry, and the possibilities for obtaining the benefits of co-operative action through a committee are large in promise. Opposed to such a scheme there is the bogey of "local conditions," together with the somewhat surprising question, which seems to be raised in some quarters, as to the benefits accruing from standardization of any kind. Of these two objections the former is undoubtedly the most difficult to overcome, not because of its soundness, but on account of its very impregnability to the effects of logical reasoning. Certainly no more successful answer than "local conditions" can be found for the natural question as to why a side-post spacing of 29⅝ in. is believed to be required in one city while 29¾ in. is put forward as the only dimension suitable for the needs of another locality. No other answer supplies so perfectly the demand of human nature for a catch phrase that will effect deliverance from the necessity for thought.

The question as to the concrete benefits of standardization is more readily met, although it is raised with an astonishing degree of regularity. Even our correspondent of last week, himself, seems to doubt the probability of making appreciable savings by uniformity in actual dimensions and advocates only standard methods. To this it is only necessary to advance the fact that, even to-day, one of the prominent builders of electric railway cars makes a practice of cutting the price of a car at least $100 and gives thirty days quicker delivery if a duplicate design is accepted, the actual saving depending upon the opportunity for distributing the development charges. This practice is not a surprise to anyone who has seen the vast number of different forms that the car builders are forced to construct, sometimes for orders of only three or four cars, owing to minor variations in dimension or outline. That a car with a roof contour formed in an ellipse is more efficient than one in which arcs of circles are used seems hardly reasonable. Yet every day the railways are being forced, by the lack of accepted standards, to pay for new dies that produce no more important changes than just this. It is a situation which will at least stand a thorough investigation, and even a committee that was organized only to investigate the subject could employ its time to excellent advantage.

Modernizing 2411 Cars

More than $1,000,000 Has Been Spent by the Brooklyn Rapid Transit System in Completing at Its Own Shops the Further Improvement and Rebuilding of 1612 Cars and Equipping 1133 of Them with Air Brakes—In Addition, Air Brakes Are to Be Installed on 800 Open Cars, Making a Total Expenditure of $1,250,000—The Grand Total for Improved Brakes Alone Will Be About $750,000

The mechanical department of the Brooklyn Rapid Transit System is completing the further rebuilding and thorough modernization of 1612 surface cars, or all of those exceeding 25,000 lb. dead weight each, to fit them for operation with improved maximum traction trucks with semi-automatic air brakes, automatic slack adjusters, emergency conductor's valve, geared hand brakes for contingency service and minor betterments. The work was begun on Oct. 1, 1913, at the Thirty-ninth Street shops, where it has since been prosecuted at the rate of seven cars a day. The job comprised passenger cars of the following types: 554 double-truck closed, 605 double-truck semi-convertible and 452 double-truck convertible cars.

Included in these figures are fifty closed and twenty semi-convertible cars of the Coney Island & Brooklyn Railroad, recently taken into the Brooklyn Rapid Transit System and twenty semi-convertible cars of the Bridge Operating Company. The cost of the betterments on these cars, as hereinafter detailed, was estimated at $987,000. In addition, 800 double-truck open-bench cars will be equipped with air brakes during the next three winters, making a grand total of 2411 cars. One of the most remarkable features of this modernization was that so many cars were handled without affecting the transportation department. This was made possible by working on the closed cars during the periods when the open-bench cars could be used in their stead. Furthermore, the rebuilt cars were immediately available for an increase in continuous operating mileage because the addition of the air brakes, American Type F automatic slack adjusters and other improvements permitted the mileage between inspections to be raised from 600 to 1000 miles.

DETAILS OF IMPROVEMENTS ON CLOSED CARS

As several classes of cars were put through the shops the work may best be described by beginning with the cars that required the greatest degree of alteration. This group comprised 554 double-truck closed cars of the company's 300, 500, 700, 1100, 1700, 1900 and 2100 series, all of which have longitudinal seats, an average body length of 25 ft. and an average over-all length of 34 ft. 5 in. The average weight of these cars before

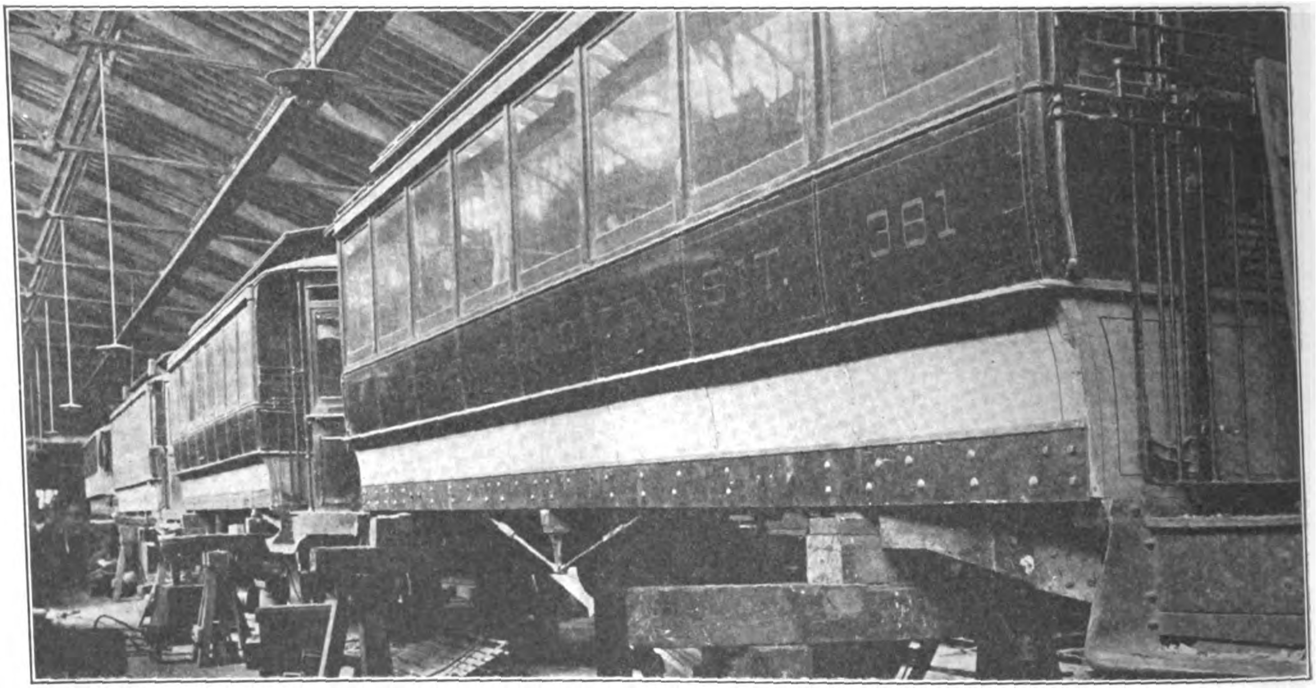
B. R. T. RECONSTRUCTION—DETAILS OF UNDERFRAME, SHOWING ADDITIONAL MEMBERS, REINFORCEMENT, METHOD OF PROVIDING FOR LARGER WHEELS, SAFETY FEATURES OF AIR-BRAKE EQUIPMENT AND ARRANGEMENT OF APPARATUS rejuvenation was 27,740 lb. After the change it was 31,500 lb.

In this group the underframe was rebuilt and cast-steel bolsters were installed, owing to the substitution of the Brill 39-E-1 bolster type maximum traction truck for the original 22-E design. The use of the cast-steel bolster necessitated the installation of 3-in. x 4-in. yellow pine longitudinal members 5 ft. long between the bolster and the intermediate cross-members of the underframe. To allow proper clearance at curves for the center-bearing trucks it was necessary to cut the side sills and then to reinforce them with 6-in. x 3½-in. angles 5 ft. 6 in. long placed over the sills at the four locations indicated on an accompanying drawing. To strengthen the car framing still further because of the extra equipment concentrated at the center, a ½-in. x 7-in. machined steel plate was bolted on the outer side of the side sills for their full length, or approximately 25 ft. The body side bearings consist of flat steel pieces 1-in. x 4-in. x 24-in., properly curved at the ends.

The use of wheels of 34-in. diameter instead of 33-in. diameter made it necessary to get extra clearance. This was obtained by sawing out a portion of the flooring, covering it with No. 14 gage steel and nailing on the edge a pair of 3-in. x ½-in. wooden strips to make a wheel housing. The new steel flooring is invisible to passengers as it is covered by the usual maple stripping.



B. R. T. CAR RECONSTRUCTION—VIEW OF SEVERAL RECONSTRUCTED CARS, SHOWING SIDE SILL REINFORCING PLATES

The foregoing body changes were common to all of this rolling stock, but in many instances variations in cars which had been furnished originally by different builders were standardized for such features as platform knee clearance and spacing of cross-sills. The underframe changes were actually less troublesome and cheaper than the preparation of a large variety of brackets, hangers and other fittings aside from the fact that the completed cars now have the advantage of a standard layout of equipment.

The new trucks are of the ball-bearing center plate type. They are designated 39-E-1 as they differ from the 39-E in the way of hanging the pony brake shoes, that is to say, each pony shoe is carried from the upper part of the truck to permit both hangers to be connected by means of a solid beam. On the other hand, the 39-E truck had a sliding beam at the bottom of the truck, and the consequent irregular displacement of the hangers tended to eccentric wear of the shoes. The release springs of this truck are also of flat instead of coil type. The trucks have pressed-steel wheel guards which may be adjusted in accordance with wheel wear by using a bracket with properly spaced holes.

The air-brake equipment was furnished directly by the New York Air Brake Company, but it includes both Westinghouse and National parts, as noted. The same equipment was applied to all cars, except that 452 cars of the present group were equipped with D-1-EG compressors, reservoirs and cylinders transferred from the larger convertible cars as hereinafter described. Otherwise every car carries the following combination: Light-weight type-S brake cylinder with J-M expansion rings, 120-lb., 16-in. x 48-in. reservoir, 130-lb. National A-6-B compressor, 642-lb.; Westinghouse D-1-G governor, Westinghouse S-Y-2A motorman's valve, conductor's emergency valve installed outside of bulkhead and connected to a Westinghouse H-1 emergency valve installed under the seats to prevent freezing. The conductor's valve can be operated from any part of the car by pulling a red cord. The total weight of the air-brake system, including all piping and fittings is about 1500 lb. The range of braking pressures is 60 lb. to 75 lb. At 60 lb. the braking effort exerted is equivalent to 90 per cent of the car light. This practice is uniform for all types of B. R. T. surface rolling stock.

The compressor is the National A-6 Form B, which is an improvement over the manufacturer's A-5 Form B. The latter design is a light-weight type of which 200 were purchased by the Chicago Railways in 1913. When the A-5 Form B compressor was considered for Brooklyn it was subjected to a detail inspection by the railway's equipment engineers and maintenance foremen, and in accordance with their suggestions the manufacturer made four changes as follows:

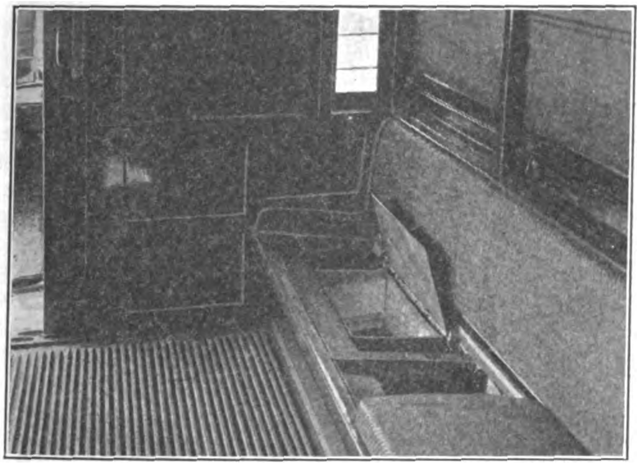
The rivets by which the field coil spring plates are secured to their tie pieces are driven flush in countersunk holes so that there is no projection about the surface of the spring plates on the coil side. This prevents an improperly driven rivet from penetrating the insulation of the coil.

The counterbores for the lock washers which serve to prevent the nuts working loose from the bolts by which the laminated tips are secured to their poles were decreased in diameter from 1 in. to 13/16 in. Therefore, should a lock washer break it cannot work out from under the nut and thus permit the bolt to be drawn in against an armature.

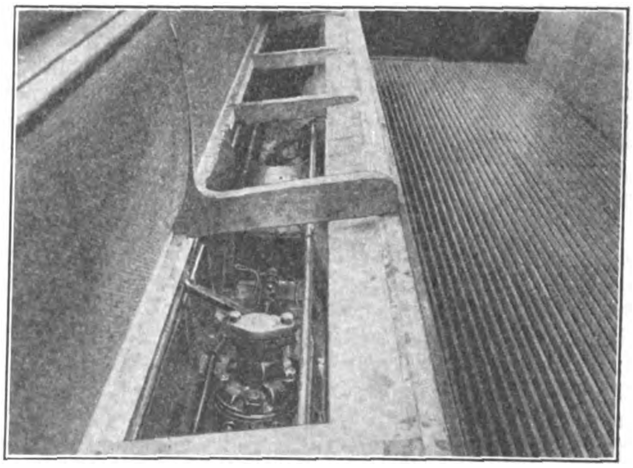
An additional cleat is provided for the purpose of securing the lead which runs from the field coil to the brush-holder to the top of the motor frame.

An asbestos liner is placed under the sheet-iron top cover in order to seal this cover against moisture and also to afford greater protection from the brush-holders flashing to ground.

The geared hand brake is of the Peacock "Improved" type, geared 12:40. It is connected with a brake shaft consisting of a 2-in. double extra strength welded steel pipe to which the sheaves are attached. Two 12-in. diameter sheaves are pulled from the hand-brake rods, and these are on the same shafts as the 6-in. diameter sheaves which are connected to the live levers. The use of the sheaves instead of the customary combination of levers for multiplying the braking effort was due to the limited space and to the consideration that sheaves allow a straight pull to be obtained under all conditions. With the geared brake a braking effort of 40 lb. to 45 lb. at the handle is sufficient to take care of regular operating conditions. It may be interesting to point out here that it is customary for the Brooklyn company to operate the geared hand brake on air-brake cars in certain specified zones on each trip to be sure that it is in good working order. The geared brake will also replace the staff brake even on those cars which are not equipped with air brakes.



B. R. T. CAR RECONSTRUCTION—LOCATION OF PNEUMATIC SANDBOX UNDER SEAT



B. R. T. CAR RECONSTRUCTION—LOCATION OF EMERGENCY VALVE UNDER LONGITUDINAL SEAT

The brake rigging is of the closed jaw type with safety bolts, so that if the shopman omits any pins the brake rigging will continue to operate. It will be seen also that the hangers which support the live and dead levers have stops placed in such positions that the breaking of one of the truck pull-rods will still permit braking on the other truck.

The Wyoming pneumatic sanders which have replaced the old wooden sandboxes with hand mechanism were described in the ELECTRIC RAILWAY JOURNAL for Nov. 15, 1913, page 1063. These sanders can be operated by the motorman when his valve is in either the emergency or release positions. An interesting point about this installation is that the box, which is made of sheet metal, is set under the longitudinal seats with a gap of about 1 in. between the back of the box and the seat frame. Although the cover of the box is hinged to the seat frame, any water which might drip through the seat falls behind the box instead of into it.

The limited space conditions for the installation of the extra equipment will be appreciated from the fact that on this group of cars an area of 5 ft. x 6 ft. had to suffice for the cylinder, compressor, reservoir, brake sheaves, pull rods, levers, slack adjusters, fuse boxes, resistors and cooling coil. Both the slack adjuster and resistors have shields to throw off mud and wheel wash.

SEMI-CONVERTIBLE CARS

The 605 semi-convertible cars were made up of double-truck cars of the 700, 2300, 2500, 2700, 2900, 3100, 3300 and 3500 series and twenty Bridge Operating Company's cars which have a longitudinal seat layout and average 28 ft. over the body and 37 ft. 4 in. over all. Of this group 100 of the 2700 series, 100 of the 2900 series and fifty of the 3100 series had been equipped with the revised underframe and cast-steel bolsters in the year preceding the installation of air brakes, because of the adoption of the Brill 39-E, 39-E-1 and Standard 036 trucks. The layout of equipment on these cars is similar to that of the closed cars already described. Of the remaining cars in this group 100 had been equipped with Standard 045 trucks and 200 with Peckham 14-D-5 trucks, all of which have been retained under the same cars. These cars weighed from 33,000 lb. to 35,000 lb., and their increase in weight due to air brakes, etc., has averaged 1500 lb. to 2000 lb. As the area for the equipment was somewhat greater, namely, 8 ft. x 6 ft., the larger, or 16-in. x 60-in. reservoir was used and placed outside the brake rigging, while the resistors are at the ends instead of at the sides.

CONVERTIBLE CARS

The 452 double-truck convertible cars were made up from the 3700, 3900, 4100, 4300 and 4500 series. These cars are of the cross-seat type which immediately preceded the center-entrance type. Their body length averages 31 ft. 5 in., their over-all length, 42 ft. 6 in., while their weight varies from 49,000 lb. to 52,000 lb. Although these cars had originally been equipped with air brakes and slack adjusters it was held wise to replace the air-brake outfit with larger units in order to get increased mileage between inspections. The lower total brake leverage obtained by using 10-in. instead of 8-in. brake cylinders makes it possible for the slack adjuster to take care of the wheel shoe slack for 1000 instead of 600 miles. The 16-in. x 48-in. reservoir, therefore, was supplanted by one of 16-in. x 60-in., the 8-in. x 12-in. cylinder by one of 10-in. x 12-in. and the D-1-EG Westinghouse compressor by the National A-6-B. The motorman's S-Y-2A valve with connections to the Wyoming sander, the sander itself, the conductor's emergency valve and the emergency valve were also added. The replaced reservoirs, cylinders and compressors were applied to the smaller closed cars, as mentioned earlier in this article.

OTHER CARS

During the reconstruction period described the mechanical department also rebuilt and re-equipped seventy-two cars of the lately acquired Coney Island & Brooklyn Railroad, including the first installation on these cars of conduit, switchboards and other B. R. T. standard practices. Fifty of the heavier Coney Island open cars will also be fitted with air brakes. Of the rolling stock of this company as acquired, sixteen cars were equipped with air brakes and to these were added the emergency features of the semi-automatic equipments. The 800-odd open cars will be taken in hand late in the autumn. They will be fitted with the standard air-brake layout, but no slack adjusters will be used owing to the retention of the No. 22-E trucks under these short-season cars.

The Use of Vanadium in Steel Rails

A Small Percentage Reported to Produce Rails of Great Strength, Toughness and Resistance to Wear

In a report of a recent test of vanadium steel rails in comparison with plain carbon steel rails of the same section and manufacture it is stated that, through the addition of a small percentage of vanadium to standard rail steel, rails of exceptionally great strength, toughness and wearing quality are obtained. Briefly summarized, the salient facts as shown by analysis of the results of these tests are as follows:

In manufacture rails made from vanadium steel roll clean and show no tendency to crack or tear. No change is necessary in the gages, as vanadium steel takes the same standard gage as plain carbon steel. Nothing that is developed in the melting, casting, heating or rolling of vanadium steel indicates that the mill output will in any way be reduced. The percentage of yield of rails from the ingots is equal to or even greater than for simple carbon steel rails, and the evidence is that there will be less scrap from cracking or tearing in the rolls and also that the percentage of second quality rails will be less.

In the tests the vanadium steel rails met all the requirements specified for ductility and deflection and were stiffer or more resilient than the 100-lb. carbon steel rails of the same section with which they were compared. The vanadium steel rails deflected about the same amount from an 18-ft. blow as the carbon steel rails did from a 15-ft. blow.

The elastic limit or useful strength of vanadium steel rails averaged more than 40 per cent higher than the simple carbon steel rails, though the latter had 50 per cent higher carbon content. The ratio of elastic limit to tensile or breaking strength was 70 per cent or more for the vanadium steel rails, as compared with about 57 per cent for the carbon steel rails. The ductility or toughness of the vanadium steel rails also showed higher than for the carbon steel rails. These tests are a direct measurement of the superiority of the vanadium steel over the carbon steel rails.

Alternation impact tests proved that vanadium steel of high elastic limit had great endurance under repeated stresses and was free from brittleness. Although the vanadium rails were very much harder than the carbon steel rails with which they were compared, the bond tests were equally as good.

The vanadium steel rails showed great uniformity of hardness throughout the entire section and were from 10 per cent to 35 per cent harder than the carbon steel rails of 50 per cent higher percentage of carbon. This superior hardness, combined with the high elastic limit and the great toughness of the vanadium steel rails, indicated a great increase in wear resisting qualities.

Comparative tests to determine resistance to wear showed a very great increase in wear resisting qualities for the vanadium over the simple carbon steel rails. The vanadium steel rails showed no segregation, the variations in analysis noted being within the allowable limits of analytical error, although standard high carbon steel rails usually show segregation.

Sections from the vanadium steel rails etched with boiling dilute sulphuric acid showed a remarkably dense, uniform structure, free from piping, slag and other defects. The contrast in this respect with the etched sections of the carbon steel was very striking, although the carbon rails used in the tests were selected at random by the makers.

From the results of the tests the American Vanadium Company recommends the following chemical specification for vanadium steel rails:

	Per Cent
Carbon	0.45 to 0.60
Manganese	1.00 to 1.25
Silicon	over 0.10
Phosphorus	not over 0.05
Sulphur	not over 0.05
Vanadium	4 lb. added per gross ton

This specification is expected to give rails with from 30 per cent to 50 per cent higher elastic limit, or useful strength, combined with greater toughness and hardness than simple carbon steel rails with from 0.62 per cent to 0.75 per cent carbon content. The vanadium steel rails will show even greater superiority in comparison with carbon steel rails of 0.45 per cent to 0.60 per cent carbon. The relatively low percentage of carbon recommended, together with the great freedom from segregation of vanadium steel, should result in the practical elimination of the danger of failure from internal fissures, or silvery oval spots.

These rails were rolled by the Cambria Steel Company.

Praise from Governor-General of Philippine Islands

Reference has been made previously in the ELECTRIC RAILWAY JOURNAL to the damage done by the storm at Manila, P. I., on Wednesday, Sept. 2. This is said to have been the most dangerous and most destructive storm known in the history of the city, which at one time was threatened with total darkness and the loss of many lives. The Manila Electric Railroad & Light Company rose to the occasion and C. Nesbitt Duffy, vice-president, has received commendation from Francis Burton Harrison, Governor-General of the Philippine Islands, for the work which his company did in restoring service. In his letter to Mr. Duffy Mr. Harrison said that in view of the continued rains and the expectation of high seas the situation of the people in the flood districts would have been very much worse and the efforts to aid them would perhaps have been unsuccessful in many cases had not the company been able to furnish light.

Mr. Duffy read this letter to twenty-two members of the company's staff of officials, departmental heads and assistants who assembled at the bimonthly conference held Sept. 12. In this way the rank and file of the employees numbering about 1300 were apprised of the recognition accorded them by the Governor-General for the service which they performed. The work of the men connected with the company made it possible to light the entire city Wednesday night by 7 o'clock.

Depreciation, Repairs and Valuations

Abstracts of Papers by Halford Erickson and Dr. A. C. Humphreys Before American Gas Institute

Among the many papers presented at the annual meeting of the American Gas Institute held in New York last week were several of particular interest to the electric railway industry. The text of these papers, abstracts of which are published herewith, is subject to final revision for publication in the Gas Institute *Proceedings*. Halford Erickson, of the Railroad Commission of Wisconsin, presented a paper on "Depreciation Problems." Dr. A. C. Humphreys, president Stevens Institute of Technology, read a paper on "In Rate Fixing by Commission Should 'Depreciation' Be Deducted from Plant Valuation?" A report was presented by the committee on rates which recommended the establishment of a permanent standing committee to deal with this subject. The meeting recommended the creation of the committee, and the matter now goes to the board of directors for final action. The members of the committee on rates were: Dr. William McClellan, chairman; A. E. Forstall, R. G. Griswold, C. N. Jelliffe and A. S. Miller.

MR. ERICKSON ON DEPRECIATION

In his paper Mr. Erickson dealt mostly with financing and accounting for depreciation and with certain questions involved in distinguishing between depreciation and ordinary repairs. There is still considerable dispute as to how depreciation should be measured. Life tables properly kept, classified and used throw a great deal of light upon the question. This may also be said of personal inspections of the property and the conditions by which its life is affected, especially when they are made by competent parties. The best and most satisfactory way, however, is to use both methods.

Only in exceptional cases, such as the destruction of property due to unforeseen and undeserved calamities or causes, and under highly abnormal conditions in certain other respects, is it justifiable to charge renewals to capital. In order to prevent serious fluctuations in the operating expenses, it is best to provide for depreciation in advance through regular annual charges against earnings. Larger plants, such as railways, are often in position to adjust their renewals so that the cost remains fairly constant from year to year. In such cases it may not be necessary to provide for depreciation in advance, since the cost of the renewals can be charged directly to operating expenses. Under this practice, however, there is often a great deal of accrued depreciation that is not provided for through reserves.

That depreciation in a broad sense includes repairs is evidenced by the fact that it is the purpose of depreciation to keep the cost of the property intact. Yet the integrity of the investment cannot be maintained through depreciation allowances alone unless these allowances are large enough to cover repairs. While it is suggested that depreciation and repairs should be kept apart, these suggestions do not mean that it is believed that these items cannot possibly be properly dealt with if combined into one. On the contrary, such combinations might be practicable not only in the provisions that are made for these costs, but also in the expenditure of these provisions. Nevertheless, there are certain advantages in keeping depreciation and repairs apart that should not be overlooked, said Mr. Erickson. Such practice seems to be more natural and therefore more easily understood. It would seem to permit closer estimates of the respective costs of these items and to facilitate the closest practicable adjustment between actual physical depreciation and the accounting reservations made to offset such depreciation.

PAPER OF DR. HUMPHREYS

Dr. Humphreys said that, apart from the method pursued as to the making of the estimate and the accuracy of the estimate, however prepared, depreciation, meaning the accrued liability for the deferred or periodic renewals of plant, should not be deducted from the valuation of the plant. In opposing deduction from plant valuation for depreciation it is assumed that the plant is maintained through current expenditures for repairs and renewals in a condition to render to the ratepayer effective and economical service; that the cost of deferred or periodic renewals is included in the cost of service and that, therefore, the public service corporation can be held liable for the renewals when necessary; and that depreciation so defined is not the reduction in worth or value as viewed by a possible purchaser but is the accrued liability of the owner to renew all parts of plant as these parts become uneconomical or inefficient for operation because of physical decay, obsolescence, or inadequacy.

Dr. Humphreys added: "Unfortunately, the representatives of public service corporations are not infrequently led astray on this question. Some are misled by their failure to differentiate between actual depreciation and the accrued and accruing liability for renewals in prospect. Others are not so misled but weakly argue that, as the commissions and courts take the position that depreciation should be deducted, they might as well conform to this position. Not only is this not honest to the public service corporations but it is not honest to the commissions and courts, for the honest members of these bodies have the right to look to us to educate them in matters more particularly pertaining to our profession."

An earnest protest was entered by Dr. Humphreys against the methods "pursued by not a few 'valuation engineers,' namely, in following, more or less blindly, tables of average lives for the several types and parts of plant." These tables, if founded upon actual facts at all, are the result of averaging widely differing data. Such averages are not applicable to a specific case, though they might be of value in connection with generalizations. As a matter of fact, in Dr. Humphrey's opinion, these tables are, as a rule, not the average of actual results, though they may be the average of differing opinions.

Record for New Ties and New Rail on New Haven Lines

More new ties and more new rail were laid on the lines of the New York, New Haven & Hartford Railroad in the fiscal year ending June 30 than in any year of the past decade. The number of new ties laid last year reached the record figure of 2,060,485, an increase of 14 per cent over 1913. Out of the $1,758,023 spent for ties of all kinds last year there was distributed along the company's lines the sum of $1,374,160. This money went to farmers and owners of small woodlots, as well as to local lumber companies, payments for ties running all the way from $1.25 to $10,000. Figures compiled by the maintenance department of the road show that 25,783 tons of new rail were laid last year, an increase of 3173 tons over the previous year. Seventy-two per cent of the new rail laid was 100-lb. rail. In 1913, 22,610 tons of new rail was laid, of which 52 per cent was 100-lb. rail. The 100-lb. pattern is now used on all of the main lines of the system.

Group Insurance on Electric Railways

General Outline of Group Insurance Theory and Practice as Followed by the Equitable Life Assurance Society, the Travelers' Insurance Company and Others for Electric Railway Employees

One of the most interesting departures in electric railway welfare work for the benefit of employees within the last year has been the adoption of the plan of group insurance by several companies. The latest company to adopt the plan is the Meridian Light & Railway Company, Meridian, Miss. This follows the earlier adoption of similar plans by the Pittsburgh (Pa.) Railways and The Southwest Missouri Railroad, Webb City, Mo., and of slightly different arrangements by the Third Avenue Railway, New York, and the United Railroads of San Francisco, indicating that insurance of this character is attracting the attention of railway companies and deserves comment in these columns.

Meaning of Group Insurance

The term "group insurance," as it is in use to-day, indicates a particular kind of insurance under which a large number of lives that preserve the averages required for select life insurance are insured under one general policy or blanket contract. Where the group as a whole entails no element of adverse selection and is of sufficient size, and where all conditions as to environment, occupation, etc., are favorable, medical examinations are waived, provided every member of the group is insured and newcomers are subject to medical examination.

SPECIMEN

FORM OF INDIVIDUAL POLICY PRESENTED TO EMPLOYEES, PITTSBURGH (PA.) RAILWAYS

Plan of Equitable Life Assurance Society

One of the leading exponents of this plan is the Equitable Life Assurance Society of the United States, whose insurance covers the Pittsburgh (Pa.) Railways, The Southwest Missouri Railroad, Webb City, Mo., the Meridian Light & Railway Company, Meridian, Miss., and the Pittsburgh, Harmony, Butler & New Castle Railway, Pittsburgh, Pa. The chief application of its plan lies in the insurance of all employees under one blanket policy that provides insurance protection to each employee as long as he remains in the service of the employer. The form of policy presented to the employees, which is reproduced herewith, is, for simplicity and clearness, an excellent example of what many insurance men have asserted could not be done with insurance policies. The back of the policy contains only the name and a place for the naming of the beneficiary. Where the group is of sufficient size, 100 or more lives, and of the required quality, the employees are not subjected to individual medical examinations, except in states where the law requires this. Under-aged and over-aged employees are accepted in the group if the proportion of such applications is not excessive. This does not mean, however, that any group of applicants of 100 or more would be acceptable under the group rule. Each group is investigated as a group, environment and general conditions under which the individual works being taken into consideration. While any group to be acceptable must be found to measure up to the requirements of the company, yet the fact that it is possible to do away with the medical examination allows the acceptance of many individual risks and classes of risks which otherwise might be rejected by the company.

The amount of insurance is usually one year's wage, with a maximum limit of $3,000 to any one employee. Any arbitrary sum of insurance within a reasonable requirement, however, will be granted, provided the amount of insurance follows certain class rules and is not left to individual selection. The plan used is the yearly renewal term plan. The cost of the insurance is vastly reduced over the cost to carry the same amount of insurance in individual policies, since the group insurance system eliminates most of the agency expenses, individual collection expenses and medical examination costs.

Cost Statistics

It would cost approximately $1,250 a month in premiums in order to insure 1250 employees with an average annual wage of $800 each and not above thirty-five years of age, with a payroll of $1,000,000. This gives an annual cost of $15 per thousand of insurance. A safe general estimate of the cost to insure all employees for a unit of one year's wages, as described above is, approximately 1½ per cent of the payroll. To obtain a correct statement of the cost, it is necessary for the electric railway to fill out census slips giving the wage, age and other desired information concerning the employees, such as occupation, particular duty, length of service, etc. The reason for this is that without knowing the distribution of ages and wages of any given group, it would be impossible for the insurance company to quote rates. If the company desires to insure on a flat sum basis, say, $1,000, it is necessary to submit a schedule showing only the age of each employee. From these returns the actuary of the company can compute quotations, but any calculations made are construed as approximate on account of the constantly changing ages and because of terminations, entrances and other changes in the group.

The cost of the group insurance as noted can be substantially reduced, however, according to the plan of the Equitable Life Assurance Society, whereby it segregates all group insurance transactions into one department and makes a premium refund each year in the form of a dividend determined by the year's experience. There must be taken into account, of course, the normal increases in rate from year to year following the increases in age under the yearly renewal term plan, but this is more than offset by the reduction in cost due to dividends and the tendency of a going group to maintain a stationary age limit. Under this plan the group patrons become co-insurers in a sense, and the net cost is materially reduced. The experience of some public utility groups indicates that a net cost of only about $1 per $1,000 of insurance is possible under this system. In one case in particular, that of The Southwest Missouri Railroad, which adopted the group insurance plan in March, 1913, the railroad was notified at the end of the first year that there was available under its group policy a dividend of $924.78, which it promptly applied toward increasing the insurance benefit to $1,200 per man, instead of $1,000.

CHANGES IN GROUP AND PAYMENTS

For the protection of the employer and the company a test of the insurability of new employees is required. This test is adapted to leave the employer reasonable latitude in the selection of new employees and yet to protect him from the physically unfit as well as to protect the insurance company in maintaining the standard of the group. Subject to this qualification regarding the new employees, the group policies respond to all changes in the units of the groups. The insurance company automatically increases the insurance when the wage is increased, and it is automatically relieved of a risk at the instant when any employee's services terminate or to the extent that his wage is reduced. Notice of all changes is simply required by the insurance company within a reasonably short time from the date thereof. For the purpose of rendering a railway easy facilities at short intervals for changing the units in the groupings as represented by changes in employees, the business is put on a monthly basis.

The method used by the company in paying claims is the lump sum cash payment, although the instalment method, whereby payments are made over a period of years, can be substituted and has advantages over the lump sum method when the amount of insurance supplied is sufficiently large. When the wage basis is used, a maximum limit of insurance is fixed so that the higher salaried employees share in the benefits only up to a certain amount, and sometimes a minimum is arbitrarily fixed so that no salaried employee will receive less than a certain sum. A popular feature of the plan based on wages is a fixed funeral benefit of $100 or more in addition to one year's wages. The funeral benefit is of equal amount to all, independent of wages.

ELECTRIC RAILWAY HAZARD

In view of the prevailing popular idea that the electric railway industry is full of extra hazards, it is interesting to note what William J. Graham, superintendent of the group insurance department of the Equitable Life Assurance Society, says on this point. According to Mr. Graham, instead of being a greater risk from an insurance standpoint, the electric railway and light industry presents one of the highest types of life insurance risks, as far as the employees are concerned. "There has been," continues Mr. Graham, "more good judgment exercised in selecting men of physical and mental fitness for work with street railways and light and power companies than for most other occupations within our experience. Our investigations show that health examinations and physical tests which are now generally coming into vogue have been for years an established fact in the electric railway and lighting field. The hazard from this industry has been so present in the public mind that the officials of the companies have centered their attention on it to its practical elimination. In a street railway group employing 1000 men not more than fifty can really be said to be subject to any extra occupational hazard. The remaining 950 are not in touch with any department in their business that adds hazard as life insurance understands hazard, whereas the whole 1000 are held up to a standard of physical and mental fitness higher than is required in almost any other business. Among the relatively small percentage coming in contact with the wires or other elements of hazard every precaution is taken to reduce this hazard to an almost disappearing point. This is one of our most pleasant revelations. Our group policies are issued without medical examination but under conditions that give us favorable mortality because the risks are favorably selected by the employer, and in no industry does the employer's selection amount to more with us than in the street railway and allied industries."

SUCCESS OF GROUP INSURANCE

From the managing officials of the different industrial plants and public service corporations where the group insurance plan has been adopted there have come words of general approbation and appreciation of its good points. It is generally stated that the adoption of the plan has resulted in a closer union between the companies and the employees, and it is felt that the goodwill established among the employees has been more than sufficient compensation for the money expended. Moreover, the railway reaps added gain through the retention of experienced men in the service on account of such added inducements. In speaking of the experience of the Pittsburgh, Harmony, Butler & New Castle Railway, S. H. Waddell, secretary of the company, said: "While our experience in this welfare work extends over a period of less than eleven months, we are satisfied that it has been a good investment for us and has resulted in bringing the employer and the employee closer together and has stimulated a better, more thorough and more consistent service on the part of all employees."

SYSTEM OF TRAVELERS' INSURANCE COMPANY

The Travelers' Insurance Company of Hartford, which has insured the Third Avenue Railway, New York, has a group insurance plan somewhat similar to that of the Equitable Life Assurance Society. It has the same factor as the Equitable Life Assurance Society and its rate is slightly lower, but it does not return anything in the form of dividends. The Travelers' Insurance Company has a group insurance plan for life, health and accident insurance. If the insurance is taken out covering life there may be also insurance for health, or for both health and accident insurance. The life rate is figured on the basis of $1,000, but employers figure on the basis of a certain percentage of the payroll. The accident insurance rate is figured as a payroll percentage. The Travelers' Insurance Company makes a preliminary investigation of all proposed risks and examines new employees. Changes in rates caused by changes in wages are adjustable at the beginning of the following month. Some of the questions that the company looks into in its preliminary examination are as follows: the number of each nationality represented among the employees when more than 10 per cent of the whole; the location, construction and sanitary condition of the plant; the provisions and equipment for treating accidents and illness at the plant; the examinations given to an employee before and after beginning service, the amount of welfare work done, the average salary per year, the proportion of employees having a yearly vacation with continuance of salary during that time, the working hours, the maximum and minimum ages of employees, and special hazards in the business.

OTHER SYSTEMS

The group insurance plan has also been adopted by the Aetna Life Insurance Company, the New York Life Insurance Company, the Metropolitan Life Insurance Company and the Connecticut General Life Insurance Company. The activities of these companies have been entirely along industrial lines, however, no policies being written for electric railways. Hence what provisions these companies would make for group insurance on electric railways could only be determined by an examination of individual groups.

Objections to Government Ownership

Address by W. J. Clark Before New England Street Railway Club Last Week

Government ownership was the subject of the evening at the regular monthly meeting of the New England Street Railway Club at the American House, Boston, on Oct. 22, the speaker being W. J. Clark, manager of the heavy electric traction department General Electric Company, New York. President John T. Conway occupied the chair and a large and enthusiastic audience listened to the reading of the paper, which is abstracted below:

The greatest possible value which can be derived from electric railway organizations is to so qualify their members that they at all times can intelligently, diplomatically and yet militantly set forth as quasi-public servants and as good citizens the maximums of economic truth on public utility questions. A moral obligation rests upon us to impart to the public the results of our experience obtained in its service. No one can foretell how soon it will become impossible to cause the masses of the people to think straight on public utility issues, until they have later on paid the penalties of government ownership, toward which they have secured a long start through improper leadership and misunderstanding. This agitation is very much alive and presents perhaps the most important economic problem confronting America to-day. The inauguration of public ownership would be an economic calamity to the entire country and to all citizens not so fortunate as to secure highly remunerative positions at public expense. It is most important to avoid establishing a precedent in the realization of this propaganda. Immediate danger confronts the industry, as the executives of two extensive systems have in a preliminary way been forced to cooperate with those favoring municipal ownership, in the working out of plans under which their properties may be taken over by the cities in which they are located. Sooner or later any or all of us may be forced into a like position when we can no longer consistently advise the public as to its real interests. If we do not enlighten the public, a portion at least of the responsibility is ours.

It is the duty of the industry to dispense the gospel of economic truth. There is scarcely a street railway in the country which has not been forced through unjust public pressure to make far greater capital investments, betterments and unprofitable extensions than were ever contemplated. The establishment of a flat 5-cent fare was a financial blunder from which the public has profited enormously. The monetary benefits of street railways to the public cannot be estimated, and these have been reaped without the slightest financial burdens being imposed upon the latter. There are those who would withhold from the companies the benefits of those increases in real estate and similar values which have been created by their operations alone. There is no such thing as an "unearned increment," for every increase in value is produced by human effort.

In every form of public utility effort America surpasses all other countries. Taking into consideration the comparative prices of labor, the initial cost of such facilities and the services rendered, the cost to the public is lower here than anywhere else. Wherever government ownership has been extensively undertaken the results have been unsatisfactory, fundamentally because of legislative methods and practice, which virtually prevent publicly owned enterprises being gaged by the same standards as economically owned undertakings of a similar character. The recent Congressional legislation for government railroads in Alaska exempts the roads from complying with the Interstate Commerce Commission's system of accounts. Experience with state-owned railroads in Pennsylvania and with state-owned canals in New York is most illuminating to the opponent of government ownership, which should be vigorously opposed in the interests of both public and private welfare.

Pamphlet on Needs of Latin-American Countries

A pamphlet giving the statements made by representatives of Latin-American countries at a trade conference with American bankers and business men in Washington recently, has been issued by the Bureau of Foreign and Domestic Commerce and is available for general distribution. The conference was called by the Secretary of State and the Secretary of Commerce to obtain a clear statement of the commercial needs of both the United States and the Latin-American countries and the facilities for co-operation in supplying those needs. The statements made by the Latin-American representatives set forth the conditions in their respective countries and the particulars in which the assistance of interests in the United States is desired. The opening statement by William Jennings Bryan, Secretary of State, and an address by William C. Redfield, Secretary of Commerce, are also included. The pamphlet may be obtained from the superintendent of documents, Government Printing Office, Washington, D. C., for 5 cents.

Dangers of Boycott in England

In England, since the beginning of the war, retaliatory measures have been suggested against local German-owned concerns. Recently, according to *Engineering*, a letter signed by twelve trade unionists in the employ of Siemens Brothers Dynamo Works has been sent to the press calling attention to the fact that 2000 men are engaged at the works, of whom only 4 per cent are foreigners, and not all these are Germans. If, as has been suggested, there should be a boycott of the firm these 2000 men would suffer an immediate loss of work. The town of Stafford would feel the withdrawal of some $500,000 a year now paid in wages, and for this there could be no compensation to be found in migration. The firm of Siemens Brothers, of which the Stafford firm is an off-shoot, was founded in 1847 by William Siemens.

Claim Agents' Papers and Discussions

Abstracts of Papers Presented at the Recent Atlantic City Convention of the American Electric Railway Claims Association, Together with Digests of the Printed Discussions on the Same Topics

The American Electric Railway Claims Association has just released for publication the papers and printed discussions thereon presented at the recent convention in Atlantic City, Oct. 12-16. These are in addition to the running reports of the association proceedings published in the ELECTRIC RAILWAY JOURNAL daily issues of Oct. 14, 15 and 16. Abstracts of these papers and discussions are published below.

LEGAL CONDUCT OF INVESTIGATIONS

BY E. P. WALSH, ATTORNEY UNITED RAILWAYS OF ST. LOUIS, ST. LOUIS, MO.

The foundation for a claim for damages and a suit at law is laid the moment an accident occurs. The foundation for a successful defense, if such is possible, against a claim for damages and a suit at law may also be laid at the same time if the trainmen intelligently and alertly obtain the names of the injured and of witnesses most favorably located to see what actually occurred, and also if the trainmen calmly exercise their powers of observation in order that they may afterwards relate intelligently all details of the accident. The success with which this work is done depends in great measure upon the ability of the employing officer to select proper material for trainmen and upon the instruction and training later given.

Under normal conditions, with the accident reported and the names of witnesses secured, it becomes the task of the claim department to handle the matter in the most efficacious way. If the accident is one where liability is certain, the necessity of speedy adjustment is readily apparent. The greater the delay the more danger there is of an exaggerated idea of the injuries as well as of the demands to be made. Yet from a legal standpoint it is not always safe to urge a speedy settlement for a serious accident, for the courts sometimes inquire carefully into such contracts because of the possibie inability of the injured person to comprehend fully the extent of the injury.

During the necessary interval between injury and settlement, however, whether long or short, the claim department must make an effort to ascertain all pertinent facts in connection with the accident and the injured person, such as the identity of the attending physician and facts concerning the claimant's business, his social and even his religious associations. At the outset a statement should be secured from the claimant as to the physical details of the accident, the extent of the injury itself, the previous suffering of similar or other injuries, prior claims against the company concerned or others, and the carrying of accident or liability insurance. This statement should be signed by the claimant and if possible attested before a notary public. It is desirable in large companies to have directly attached to the claim department several men possessing notary public commissions to do work of this kind.

The claimant should be examined at the earliest possible moment by the company's surgeon. If the claimant's doctor will not extend courtesies of this character or is forbidden to do so by the claimant, there is reason for suspecting the motives of both doctor and patient. The claim department must then try by its own efforts to ascertain the true situation. It is often better to risk a law suit and rely upon the time necessary to bring it to trial as giving opportunity for a more complete investigation. If it has not been possible to secure a medical examination of the claimant prior to the filing of the suit, a request should then be made as early as possible that the court compel the plaintiff to submit to an examination by some disinterested physician appointed by it. From this the defendant can determine whether it is desirable to adjust the claim or proceed with the trial.

As soon as suit is filed the plaintiff's deposition should be taken by a lawyer experienced in damage suits and not by young lawyers recently graduated from school. Depositions taken by the latter frequently contain nothing enlightening, although in importance they are equal, if not superior, to the actual cross-examinations of plaintiffs.

The particular methods the claim agent will pursue rest largely with the individual claim agent and his facilities. Expert investigators, however, should be trained for all branches of the work within the department itself, especially in companies in large cities, because their efforts are more efficacious, if later it is necessary to put them upon the witness stand, than if they were employed by agencies entirely separate from the claim department.

Within a reasonably short time after a serious accident in which a contest is apprehended, the motorman and conductor should be sent to the claim department and a very careful and comprehensive statement should be taken, acknowledged and signed before a notary public. The reported witnesses should be interviewed, their signed statements in writing taken, and, if possible, their affidavits secured. Efforts should be made to ascertain if they know witnesses whose names were not secured by the trainmen, for excellent witnesses for the defense are thus sometimes brought to light.

Employees as witnesses, in their desire to combat the attacks of opposing counsel on cross-examination, are quite likely to undo all the good work accomplished. Hence they should understand that their sole duty is to answer truthfully the questions asked. They should be reasoned with as to speed and distances, for their powers of observation are so undeveloped that if called upon suddenly to explain operating points they cannot do so with any degree of particularity. The lawyer, therefore, should be familiar with the operation of a car and the conditions accompanying the accident, and, in talking to the men before the trial, should be able to elicit from them all the facts and at the same time instill into their minds an ability to relate those facts so that the jurors may have a correct picture of the entire occurrence.

In large cities a police officer is usually present very shortly after an accident occurs and generally secures the names of the witnesses. Written and signed statements should be taken as early as possible from the witnesses whose names appear upon the police report, because this becomes public property and is generally the first source of information consulted by the "ambulance chaser." If the defense anticipates these men, there is some likelihood that a fair and impartial statement will be given.

In cases of apparently fraudulent or exaggerated claims, any sort of espionage that furnishes information as to the claimant's conduct and mode of living is valuable in determining what should be done by way of adjustment, but such espionage to be of value in the trial must be so conducted that its results can be shown to the jury. For instance, a system of photography has been used with splendid results, because at the trial pictures were shown of the claimant actively engaged in business or pleasure at times when his testimony declared him to be in bed or crippled.

The knowledge that a claimant has or has had accident or liability insurance is important as enabling the claim department to ascertain the extent of injury claimed under that policy and also to learn whether or not the company has a history of previous accidents. In this connection the index bureau is one of the most valuable sources of information, and it is to be regretted that all companies have not taken advantage of it.

The adjustment and defense of damage claims are becoming more strenuous propositions every day, as well as more expensive. The work reduces itself to a play of wits between the claimant and the claim agent, and the latter is often made a victim of unscrupulous, malingering fakirs and dishonest lawyers and doctors. A claim agent is hardly to blame if at times in repelling such assaults he meets fire with fire. The adjustment of the claim of the honest claimant is a simple proposition, but the quack, the fraud and the pettifogger cause the real troubles of the claim agent.

DISCUSSION BY MR. HOFFMAN

L. S. Hoffman, general attorney Public Service Railway, Newark, N. J., agreed with Mr. Walsh that the ability of an employee to discover flaws in the foundation of the lawsuit goes back to his selection by the employing officer. At the same time good work can be, and is, accomplished by calling to the attention of employees of average intelligence the great importance of obtaining all possible information before leaving the scene of an accident. It is particularly important to locate the exact spot and, if feasible, to call it to the notice of disinterested witnesses.

In Mr. Hoffman's opinion, the mere fact that the injured party does not comprehend the full extent of his injuries does not prevent the meeting of the minds of the parties so as to make a binding contract. Yet, if a physician employed by the defendant should either mistakenly or wilfully underrate the present extent of the injury, or disparage the future results, there would be ground for setting aside a release. A release would also be set aside where there was a mutual mistake of an actually existing fact, but a mistaken opinion as to the outcome of a known injury forms no ground for setting aside a release.

The usual excuse given when signed statements contain matter materially different from the testimony given in court is that they were signed without being read. In order to close this gap the Public Service Railway has adopted a practice of asking the signer of a paper to write above his signature, "I have read the above statement and it is correct," or words to a similar effect. Witnesses are usually quite willing to do this.

Mr. Hoffman called attention to one danger in taking depositions before trial. When the plaintiff's deposition is taken by the defendant, the defendant makes the plaintiff its witness, the result being that the plaintiff's lawyer has a right to cross-examine his client. The advantage of such a cross-examination to the plaintiff outweighs the advantage to be gained from the deposition by the defendant. In New Jersey the practice is to serve the plaintiff with interrogatories covering matters pertaining to the defense and sometimes a bill of particulars is also demanded, so that considerable information is secured which could have been obtained by taking the deposition of the claimant.

Mr. Hoffman said that his company very seldom used any secret service investigators except occasionally in criminal matters, but he considered the results of secret investigations very often important when used for the purpose of cross-examination. As to the advisability of having the court compel the plaintiff to submit to a physical examination by some disinterested physician appointed by the court, he deemed such a course of procedure not by any means satisfactory. When the claimant will not submit to a physical examination, there is usually something crooked about his claim, and a physician who is not accustomed to making physical examinations of claimants in accident cases is no match for a malingering claimant backed by the instructions of his physician and his attorney. The only proper physician to examine an unwilling claimant is an expert who, through experience, knows all the tests to be applied to determine malingering. Much depends upon the practice of the court, however, in appointing experienced men, and this can be known only through experience. It is often efficacious to bring out at the trial the request and the refusal for a physical examination, and follow this up by making a motion that the plaintiff submit himself then and there to a physical examination by a physician of the company's selection who is present. Very few attorneys dare risk refusing such a request because it would prejudice their case before the jury.

DISCUSSION BY MR. MUIR

According to Wallace Muir, assistant counsel Kentucky Traction & Terminal Company, Lexington, Ky., it is difficult to distinguish between investigating an accident from the standpoint of defense and investigating the same from the standpoint of adjustment. The object of investigating an accident is to determine legal liability. In order to determine this, the facts under which the person, or property, was injured must be fully and truthfully obtained, after which the law determines the question of responsibility and liability. Ordinarily no case should be adjusted where the company is not legally responsible for the injury inflicted, and when a case is once prepared so that a proper conclusion may be reached for the purpose of adjustment, the case should be in such a condition that it can be filed away and be ready for trial with but little additional work. In other words, preparation for adjustment is preparation for defense.

Mr. Muir drew one distinction, however, between preparation for adjustment and for defense. In adjustment the location of the accident is familiar to those concerned. In a trial before a jury all the jurors are not familiar with the surroundings, such as the character and grade of the street, its width, the position of the car tracks and the character of the car. Often it is essential that these points be brought out forcefully to a jury by photographs, diagrams and miniature constructions, and in some cases the jury may be taken to view the place of accident.

Mr. Muir emphasized the need of tact in trying to secure signed statements. The securing of a signed statement from the injured while in pain or in a semiconscious condition is of little benefit and often dangerous. The statement of a child, although bright and intelligent, should be taken in the presence of its parents, one of kin or someone closely connected with the injured. The investigator should have each person giving a statement read it over in the presence of another, the third party to witness the signature unless it is sworn to. It is not an advantage, however, as Mr. Walsh says, to have a statement sworn to before a notary public who is a claim agent or investigator of the company. The claim agent and investigator, as far as possible, should be kept in the background at the trial, for a verdict is often rendered against a company solely upon the ground of some supposed misconduct on the part of the claim agent.

In a certain character of accidents, such as when there is no question as to liability, it is very essential to see the injured as soon as possible and effect compromise. Every courtesy and attention should be extended to the injured party, frequent visits being made without any talk of compromise until the proper time arrives. The question of compromise or the merits of the case should not be discussed in the presence of any disinterested person, for in nearly every case the outsider is the one who puts the extravagant figure in the mind of the injured.

CLAIMS DEPARTMENT POLICIES AND PRINCIPLES

BY CECIL G. RICE, SUPERINTENDENT CLAIMS DEPARTMENT
PITTSBURGH RAILWAYS, PITTSBURGH, PA.

Upon my entrance into the claim business I was not particularly impressed with the attitude of the public toward the ordinary claim agent, but I concluded that something could be done to change this opinion of the public, through imitation, through trial and error or through reasoning. Not knowing where to find the thing I desired to imitate, I started by trial and error and finally took up the reasoning process. From scientific management and business efficiency, I realized there were five things to do: First, to investigate and standardize; second, to form an organization that would carry these standards into effect; third, to get the men to form the organization; fourth, to provide proper compensation for the men, and fifth, to get a relay of men so that when one left the vacancy could be filled immediately.

We changed the department into five separate and distinct bureaus—clerical, investigation, adjustment, medical and litigation. Each of these bureaus was put in charge of a chief, who was responsible for the work. When an accident occurs it is reported to the claim department and goes to each of the bureaus with the exception of the litigation bureau. This bureau has absolutely nothing to do with the adjustment of a claim. The investigation bureau is charged with getting the facts, whether favorable or unfavorable. The clerical bureau has to do with the records. The medical bureau is charged with learning the facts from a medical viewpoint and making and arranging examinations. The adjustment bureau takes care of the actual adjustment after the clerical bureau has made its records. If, after all the facts have been filed, an adjustment is not possible and suit is entered, the papers are turned over to the litigation bureau for the purpose of preparing a defense or making a settlement.

Every Saturday afternoon the different chiefs meet with myself for discussion. Each of these chiefs should know as much about all the departments as the superintendent. Once a month there is a meeting of all of the members of the departments with papers or discussions. Once a week each bureau has a meeting to talk over the details of its work. In this way every man in the department is supposed to be a claim agent, a superintendent or chief claim agent. The chiefs regard their own individual men as assistants to them, and in that way it is possible to develop men who are better acquainted with the business of claims.

In connection with office kinks, some trouble is often experienced in locating files where there is more than one office. This is overcome by a "cherry card." This must be made out and go to the central file showing the minute the file moves from one person to another, from one room to another. We have used as many as 500 cards a day, and a check for three months has shown only six errors in handling all those cases.

As to fixed principles, we have adopted for our own guidance the following six slogans: maximum accuracy, utmost expediency, absolute fairness, persistent courtesy, minimum consistent expenditures, and perfected co-operation and efficiency. By maximum accuracy we mean incontrovertible facts unearthed from all available sources. Utmost expediency means the promptest action in accord with propriety and correctness. Absolute fairness embraces a fixed, irrevocable policy of dealing with justice to all concerned. Persistent courtesy may be defined as constant politeness combined with kindliness. Minimum consistent expenditures are disbursements proportionate to all the facts, and perfected co-operation and efficiency mean working in harmony to produce the most satisfactory results with the least expenditure of time and effort.

These principles have been in use in our department for five years. In October, 1912, we had a very serious accident in which ninety-six people were injured. We started to give our principles a test on that particular case. One of the first men settled with was paid $50 for two broken ribs. When the adjuster told me how much he had paid, I sent him back with a letter and an additional $50. The man happened to be the president of the board of trade of that particular district, and he was so impressed with what he thought was an unprecedented act of courtesy that he, without any solicitation on our part, used his efforts to help us out in his territory. We built from that case right on up. Every man we went to see we told about the last man with whom we had settled, and we paid from $50 to $15,000. Despite the efforts of attorneys we disposed of every one of those ninety-six cases without a single suit being entered, at a cost of $104,000. They were handled throughout with this idea of fixed principles, which we advertised to everybody.

In addition to constantly and persistently dwelling upon these fixed principles, the chiefs of the different bureaus use the following seven guiding principles:

1. Street railway transportation companies do not insure passengers or pedestrians against injury or damage. It is wholly unreasonable to suppose all persons injured in connection with a street car are entitled to damages.

2. If an accident occurs the principal should not depend solely upon the conductor to make a report but should secure the number of the car or the number of the motorman or conductor, the exact location, and the exact time.

3. If any personal injury or property damage results for which the principal was not to blame and feels justified in making a claim, he should frankly report the details of the occurrence to the claim department, together with the names of the witnesses, and give every possible assistance in making an unprejudiced investigation of all the facts and circumstances. Only dishonest claimants object to a thorough inquiry being made to corroborate the facts.

4. A claim is purely a business proposition, not a matter of law, and should be presented and handled on the same basis as any other allegation of indebtedness. Proving a claim is the same as proving a bill for work done or goods furnished.

5. Any legitimate claimant making a reasonable request for reimbursement can secure a satisfactory disposition of his claim without the expense of assistance. Since a claim is the same as a bill it is bad judgment for a claimant to employ an attorney or enter into the embarrassment, delay and uncertainty of a suit without first presenting his proof of indebtedness direct to those whom he believes owe him.

6. Only three classes of people bring suits for damages against railways, viz: (*a*) prejudiced persons unacquainted with the principles governing the handling of claims; (*b*) persons entitled to something but who want more than they are entitled to; and (*c*) persons entitled to nothing but who want something regardless of their right to it.

7. Citizens who encourage litigation, whether "ambulance chasers," neighborhood gossips, misinformed friends, or someone seeking to profit from another's misfortune, should remember that in so doing they add a burden to every taxpayer, as the expense of the courts is assessed against them.

In addition to the above principles the company uses certain psychological processes in its claim work. The first is to overcome prejudice, the second to inspire confidence, the third to analyze and reduce to a business basis, the fourth to create a desire, the fifth to cause a determination, and the sixth is to close the transaction. By overcoming prejudice we endeavor to show by logical argument that what is true is right. To inspire confidence we mean both to trust and to rely, causing others to believe in us and realize that we are sincere in our desire to deal equitably with everyone. By analyzing and reducing to a business basis we mean to prove by calculation the weight of the facts and pay according to their value. By creating a desire we mean to bring into existence a desire for what will reasonably compensate claimants for their losses, considering the degree of such losses. To cause a determination we bring a man's mind to the opinion that he will exchange his claim for a fair price for the damage done or loss sustained. To close the transaction satisfactorily is to make amends for the injury and then satisfactorily terminate the matter.

One psychological point may well be emphasized. A person will believe anything that may be said to him unless some negative idea comes up in his mind. In order to prohibit a negative idea a positive idea must be injected, and in order to inspire a positive idea a negative idea must be prohibited. For instance, an adjuster says to a woman: "Will you submit to an examination?" or "Will you allow us to have an examination made?" or "Will you undergo an examination?" These questions immediately put a negative idea into her mind on account of the objectionable thought of undergoing or submitting to anything. In our company when an examination has been refused, declined or not granted, we write a letter simply instructing the claimant to arrange through his doctor with our doctor for an examination, without even suggesting the possibility of his being able to refuse such a request. Thus far in the list of cases handled, only one refusal to this plan has been made.

We even go so far as to prepare the claimant before he gets on the department floor. When he comes into the reception room there are many things to attract his attention and divert his mind from his real or fancied injury. There are pictures of President Taft and several local notables at a ball game in Pittsburgh, cartoons of "Mutt and Jeff" making claims, and the old picture of the cow with men at her horns and her tail pulling in opposite directions and an attorney milking—in other words, getting the cream while the claimant and the claim agent are fighting. These pictures have actually been known to turn people back to an offer already made.

The American Association has decided to adopt fixed principles and policies in order to appeal to the public. If the parent association finds this advisable, why would not the Claims Association also find it advisable? There is nothing in the principles enumerated that a company should not desire. Claim agents should assume that the public does know that there is such a thing as a claim department and that claims for damages are paid, and they should appeal to the public and put them on their honor until they do something dishonorable.

DISCUSSION BY MR. TICHENOR

In commenting upon the paper by Mr. Rice, William Tichenor, claim agent Terre Haute, Indianapolis & Eastern Traction Company, Indianapolis, Ind., said that all communities contain many excellent people in all professions and callings, and that if all men, including claimants against railroad companies, were of this character, the public would be entitled to be treated with absolute courtesy, fairness, frankness and firmness, being given full credit for truthfulness and honesty. Unfortunately, however, the portion of the public met by the claim agent and dealt with by the claim department of the present day is not composed of this kind of people. The claim agent comes in contact with only a very small fraction of the public, and a very large part of that fraction seems to be seeking something for nothing without being over-particular as to the source of supply or the method of obtainment. This class is seemingly growing larger and less scrupulous as time moves on.

It appears to be the policy of some companies to treat lawyers and doctors with great courtesy, taking care of their bills, especially the doctor's bills, for the purpose of inducing them in some way to change their methods and give the company a square deal instead of rendering all assistance possible to prosecute "fake" claims. Mr. Tichenor mentioned the case of one company that had a great number of unsettled lawsuits. In this instance the plaintiffs' lawyers were taken into the company's confidence and were treated so courteously in the settlement of the suits that the company now seldom has a suit filed against it and has not lost a suit in three years. If claim agents and claim departments generally could pursue the same policy with the same sort of success, it would be well for such a policy to be widely adopted.

In another case the claim agent of a city and interurban line said it had become such a custom with him to visit the doctor, direct him to take care of the patient until recovery and then present his bill for payment, that it really might be counted as the policy of the company. Both of the above men, the friend of the lawyer and the friend of the doctor, evidently were successful with the policy of dealing with the public in the way suggested, but Mr. Tichenor felt that the experience of claim agents has not been such as to justify the adoption of such customs as a general policy of claim departments.

Mr. Tichenor believed that while a particular claim department may adopt particular policies and principles and adhere to them more or less religiously, general policies on "the relation of claim departments to the public," "the psychology of claim adjustments," "efficiency in claim department work," or "office kinks in claim departments," are wholly impractical, if not impossible. If a general policy were adopted by the association in order to meet the exigencies of any particular case, it would necessarily have to be so modified and reconstructed to meet the peculiar circumstances and conditions of particular cases that it would not be recognized by its author.

DISCUSSION BY MR. HANDLON

J. H. Handlon, claim agent United Railroads of San Francisco, San Francisco, Cal., noted the change in the attitude of the claim departments of street railways to the public within the last few years. Many street railway claim agents early in the field prided themselves to such an extent on their detective ability that they became dominated by their suspicions and grew to consider every person dishonest who had the temerity to file a claim against their employers. They treated the claimants accordingly. Not only was it morally wrong, however, for claim agents to do so, but experience has shown that it was not good business judgment, for unfair settlements are always extensively advertised and to-day jurymen often cite such instances as their excuse for penalizing companies by awarding excessive verdicts.

The successful claim agent realizes that there are honest claimants and that the good-will of the claimant, and particularly of all attorneys and physicians with whom he has business relations, is a personal asset. Moreover, he strives to secure this good-will without any other consideration than fair and courteous treatment.

Certain electric railways are now required to pay unreasonable sums in settlement of personal injury claims owing to the fact that competitive companies are very liberal in their settlements. Other claim agents are unable to reduce their settlements to a fair basis for the reason that their predecessors, in their generosity, educated the public to expect to profit materially from street car injuries. It is very difficult under these circumstances for a conscientious claim agent to instill in the minds of claimants the fact that accidents are regrettable, that the company is adopting every reasonable precaution to prevent them, and that claimants should not seek to profit thereby.

Mr. Handlon said that it is often wise to relieve attorneys of the necessity of visiting the office of the claim agent until the claim is ready for adjustment. This can be done by having a representative gather all available facts from the attorney at his office, or, if he consents, to visit the claimant at his residence. By accommodating the attorney in this respect he is often induced to file the claim rather than litigate a case.

DISCUSSION OF CLAIMS PUBLICITY

BY JOHN J. REYNOLDS, CLAIM ATTORNEY BOSTON (MASS.) ELEVATED RAILWAY

Mr. Reynolds in his written discussion said no substantial ground exists for believing that claim departments have been benefited by publicity of accidents and the sensational illustration of fake, fraudulent, or exaggerated claims, upon which money has been paid or awarded. Claim agents should not allow themselves to be borne away, far beyond the bounds of reason, by a sudden passion to see their fake cases dramatized in story. Such publicity gives specific suggestions with examples of their application and hence serves as a guide to aid the fakir to improve on existing methods and lessen the danger of discovery. That efficiency in claim department work is made more difficult by publicity is unquestionable, and it may well be doubted whether such publicity, beyond imparting to the public the underlying principles that have actuated claim fakirs, has really accomplished the object sought. Most states have publicity laws regarding accidents, under which the public is informed, sufficiently, of all important cases.

Mr. Reynolds at this point introduced numerous newspaper stories to illustrate the reporters' method of "playing up" or "featuring" accidents, with a resulting handicap to the claim department. In his opinion, if newspapers request information concerning accidents, they should be referred to the operating department, and only in the most serious accidents, where persons are injured and removed to hospitals, should the newspapers be given the names and addresses of the injured. Such a course is the proper one for the best results of the claim department, and it is not at all inconsistent with the propagation of that necessary and desirable co-operative relation between the railways and the public.

With regard to magazine publicity claim agents should always be careful to keep in mind the distinction between publicity regarding serious accidents, and publicity concerning the methods of the accident fakir and the methods of the claim department in circumventing him. Take, for instance, said Mr. Reynolds, the magazine publication of the methods by which claim department detectives procured photographs of a farmer plaintiff at work during the haying season. While the evidence procured was of paramount importance to the claim department and perfectly proper to be used either in that department or as evidence in court, such publicity is wholly ineffectual in assisting claim agents to prevent dishonest persons from presenting fraudulent claims. It equips such persons beforehand with an accurate knowledge of what they can do to defeat the most carefully laid plans to trap them. Even admitting the interesting and entertaining character of the numerous fakir stories in magazines, Mr. Reynolds maintains that they are not helpful to claim departments, nor do they help the average citizen to realize that his individual interests, represented by minimum fares and maximum service, are menaced every time the fakir's ill-gotten gains come out of the treasury of the public service company.

To deny such publicity, however, does not mean that these fakirs should not be punished. Mr. Reynolds believes that they should be punished to the limit, but, in so doing, all things should be avoided that may offer suggestions to would-be fakirs. The sort of publicity that will help the claim department is immediate attention to complaints; prompt betterment of service conditions when they can be bettered, and the employment of trainmen who will try to please the public, who will answer inquiries as they should, who will be careful to stop cars when signals are given and who will not jostle people unnecessarily. Publicity of the fact that those essentials are not observed is bound to be felt in the claim department.

It is no exaggeration to say that the claim department of the future will be benefited by publicity. This, said Mr. Reynolds, will be caused not by publicity of accidents and claims, but primarily by the sweeping changes which will have taken place in methods of education in vogue at the present time. That a comprehensive plan of educational publicity is considered necessary to set forth the problems confronting the railways is seen in the parent association's plan for establishing a publicity bureau. A well-organized bureau should be maintained for the purpose of correcting authoritatively and publishing widely all misstatements of fact as fast as they appear. Except in cases of flagrant fraud which are prosecuted in court and which in consequence receive advertisement in that way, the claim department should be kept out of publicity schemes. Expense for publicity should be directed rather toward education along the line of preventive methods.

The accident prevention campaign which is now being seriously conducted by many electric railways is undoubtedly reaching a large portion of the public with excellent results, and claim agents should do every reasonable thing necessary to the end that no longer shall the educational leader hesitate to recognize the widespread demand for a curriculum which will better fit pupils to avoid accidents. Care, however, is to be constantly exercised to keep suggestive matter in the background.

No inexorable rule to be followed blindly under all circumstances should be laid down for claim department publicity. The point to be emphasized is the unwisdom of a pronounced tendency in the matter of claim publicity. What may be justifiable in a given case may be unjustifiable or even pernicious as a general practice. The ultimate adoption of a distinct policy in favor of education is most desirable.

With regard to publicity between claim departments of various roads, there are two general objects to be kept in mind: First, to carry on as widely as possible, with the aid of the index bureaus, a consistent campaign of education through interchange of information relative to claimants reported by the Hooper Holmes or other bureaus. Second, to assist by special work through the local index bureaus in keeping track of claimants that do an interstate business or those whose operations seem to be exceptionally active and extensive. If claim agents at all times keep in touch with this aspect of the business, they will be developing a publicity that will prove a real and permanent benefit to their departments.

NEWSPAPER PUBLICITY DISCUSSED

BY J. S. KUBU, CLAIM AGENT NEW YORK STATE RAILWAYS, UTICA, N. Y.

There is a limit to publicity in connection with claim departments just as to anything else, according to Mr. Kubu's written discussion. The real objection to the general policy of full publicity is the "ambulance chaser," who sometimes creates embarrassing situations. How much embarrassment the claim agent is put to depends a good deal on the efficiency of the department. If the claim agent takes his time and allows the "chaser" to obtain possession of the facts of a case before he himself knows them, the company will find it unprofitable in dollars and cents and will have to bear an additional burden in defending a law suit. Unfortunately, the greatest difficulty is the foreigner who cannot read and does not understand the language, for there are plenty of "ambulance chasers" who speak the foreign languages and have no difficulty in securing clients.

There ought to be a cordial co-operation between the newspapers and the claim department. When an accident occurs which has news value, the claim agent should get in touch with the newspapers and give them definite information that will correct any and all rumors. Very often it will save the city editor the task of assigning a reporter to a job. This line of work in the company should be assigned to one man. News of all accidents and litigation should reach him first and he can then use his discretion in communicating such information to the newspapers. He must, however, know how, and when, to act, and aim at the right kind of publicity rather than at more publicity.

Mr. Kubu remarked that in the matter of litigation the public records are open to inspection and it is a very easy matter to get a copy of a petition or a complaint. When an action at law has just been brought out and is called to the attention of the newspaper man, he will, if he is friendly to the company, get in communication with it and give it a chance to defend itself before publishing the case.

The "safety first" campaigns have been given great publicity by the newspapers throughout the states, and their liberal support has contributed greatly toward the success of such campaigns. This only emphasizes the great interest which newspapers have in the subject and makes clearer the value of the co-operation which should exist between newspapers and railway companies in connection with accident publicity.

Changes In New York Subway Track Practice

At the Oct. 16 meeting of the New York Railroad Club, O. O. Dixon, assistant engineer Interborough Rapid Transit Company, read a paper describing the changes that have been made in the track standards of the subway division since its opening Oct. 27, 1904.

The ballast of ¾-in. trap rock 5 in. deep has been retained, but the 5-in. x 8-in. x 8-ft. ties are renewed with 6-in. x 8-in. x 8-ft. timbers, and on curves the tie spacing has been reduced from 22-in. to 18-in centers.

Originally the inclined guard rail on curves was bolted to the low rail about every 3 ft., using adjustable cast-iron separators to take up the wear. It was soon found that the inclined guard rail was so flexible that it concentrated the pressure on bolts, causing frequent breakages. When the bolts held the wheels were allowed to side slip between the bolts, due to the flexibility of the guard rail, and much corrugation was so caused. This guard rail has been replaced by another of the same section as the running rail, having one flange sheared off, and the adjustable separators were replaced by a one-piece separator to give the correct flangeway. The gage has been widened from 4 ft. 8½ in. to 4 ft. 8¾ in. for curves between 200 ft. and 500 ft. and to 4 ft. 9 in. for curves less than 200 ft. radius.

The first 100 lb. A. S. C. E. rails were manufactured by the bessemer process of the following composition: Carbon, 0.58 to 0.63 per cent; manganese, 1 to 1.10 per cent; phosphorus, 0.09 per cent; sulphur, 0.05 per cent; silicon, 0.07 per cent. However, the specifications were gradually changed to higher carbon rails to get better wear. At present the company specifies carbon 0.75 to 0.90 per cent with an average of not less than 0.90 and manganese 0.60 to 0.90 per cent. Since 1909 the side of the rail head has been sloped to conform more closely to the shape of the wheel. Thus the vertical wear has been slightly increased and the horizontal wear decreased, thereby increasing the life of the rail. A comparison of the life of the rails and tonnage passing over a curve, which has a radius of 220 ft. and a grade of 1.15 per cent down and over which the average speed is 18 m.p.h., shows that in comparing bessemer and open hearth rails the wear is about 1 to 2 in favor of open hearth. The ratio of wear of manganese to bessemer is 1 to 9 and the ratio of wear of manganese to open hearth is 1 to 4½. The soft bessemer rails have proved more liable to corrugation than the harder rails. The manganese rail was satisfactory except that, like all other rails, it was liable to corrugate. Manganese rails are being used on most of the important curves with somewhat varying results, but the company believes that it pays to use manganese if the price is not too high, because less renewals are required.

Switches have been reinforced and the high speed switches lengthened from 16 ft. 6 in. to 24 ft. Where the former bessemer switch point gave a service of three weeks, cast manganese gives about thirty weeks, and in frogs and crossings about five times that of bessemer. Rolled manganese stock rails help greatly to increase the life of the switch points and are in general use.

The ballast in front of stations is renewed about every two years at express stations and every five years at local stations. Few ties have been renewed except at switches and on curves where they have split, due to frequent rail renewals, also where they were decayed due to dry rot. In making the renewals one rail is removed and new ties complete are installed for a rail length.

Screw spikes have not been used much because of the changes they would require and also because of the difficulty they would involve in making rapid renewals of rails.

Railway Electrical Engineers' Convention

Electric Headlights and Electrification Were Among the Subjects Discussed

The seventh annual convention of the Association of Railway Electrical Engineers opened at the Hotel LaSalle, Chicago, with a reception and dance on the evening of Oct. 26. Electrical manufacturers made exhibits in thirty-five booths and in the hotel ballroom. On Tuesday morning the first regular session was opened by President C. R. Gilman, Chicago, Milwaukee & St. Paul Railroad, who reviewed the history of the association and referred with pride to the work accomplished by it since it was formed six years ago. Following his address, Secretary J. A. Andreucetti, Chicago & Northwestern Railway, reported the association in a flourishing condition with a membership exceeding 500.

Reports of the committees on loose-leaf binders for filing specifications on reciprocal relations, and on specifications for wire crossings were brief and indicated progress. The report of the committee on data and information consisted of a tabulation of car-lighting statistics, shop and station equipment and motors for traveling cranes. On the latter topic the committee reported a chaotic condition in the matter of motor sizes, and this will probably be a subject for standardization during the coming year.

On Wednesday morning the report of the committee on standards was received and was followed by the report of the committee on electric headlights. The latter report discussed types of machine, location of generator, voltage adjustment, cab lamps, reflectors, wiring and repair parts. On the question of incandescent headlights, it was stated that while all railroads have been experimenting for some time with Mazda, tungsten and nitrogen lamps for headlights, there was none on the market with a concentrated filament, high candle-power and sufficiently long life to justify its use. The committee, however, was of the opinion that such a lamp would be produced within the next few months, as many manufacturers are now working along that line. It was predicted that when these lamps were a commercial article, the arc lamp would be a relic of the past on engines, as well as for shop and yard lighting. The report also called attention to the battery headlights which are being used with good results on the Southern Pacific Railroad. These lamps are 140-cp nitrogen-filled tungstens and require 13 amp at 6 volts.

At the Wednesday afternoon session the committee on industrial trucks recommended a standard capacity, a standard speed, a standard for tires and wheel sizes and a standard potential of 24 volts for general industrial truck service.

REPORT ON ELECTRIC TRACTION

This was followed by the report of the committee on electric traction, which was a description of existing railroad electrifications. This report was of a preliminary nature and further data, particularly as to operating costs, will be supplied in subsequent reports. Among the topics covered this year was a review of the different electric traction systems, including low-voltage and high-voltage direct current and the three different types of alternating-current systems. Regarding the choice of system, the committee states that it will depend on the extent of electrification, character of traffic and local conditions, but that it will be principally an engineering determination. The report also discusses the reasons for electrification, and the benefits to be derived from the electrification.

Upon the question of electrification of single-track roads the report states that it is a demonstrable fact that more traffic can be handled electrically than by steam on account of the facility of train movement and that it is possible to maintain higher schedule speeds without increasing the maximum speed. It can be shown in the case of a single-track road operating at full capacity, that electrification will enable it to handle additional traffic, thus postponing double tracking. The fixed charges saved on the cost of double tracking for this period may properly be credited to the electrification annual expense in calculating the economics. Other points of interest discussed included the electrification of passenger and freight yards, the sources of power supply, the construction costs and annual expense, locomotive maintenance and the economics of electric traction.

The Wednesday afternoon session closed with a report of the committee on wire specifications which was devoted to improving this association's specifications to make them conform with latest engineering practice.

New National City Bank Publication

The National City Bank of New York has this month begun the publication of a magazine called *The Americas* in the hope of bringing the business men of the United States and South America closer together and providing an instrument for the interchange of ideas regarding the aims and projects of Pan-American commerce. The October issue contains articles on the following subjects: "The Opportunities and Responsibilities of Trade Expansion," by Frank A. Vanderlip, president National City Bank; "A Message from the Argentine Republic," by Enrique Carbo, minister of finance; "The Government Work for Trade Expansion," by William C. Redfield, Secretary of Commerce; "Advantages of Direct Foreign Exchange," by John E. Garden, vice-president National City Bank, and miscellaneous articles regarding the new South American branches of the National City Bank, trade and finanical conditions and requirements in South America and also South American traveling, shipping rates and general statistics.

The National Associations and the Educational Institutions

In connection with the suggestion made by the committee on public relations of the American Electric Railway Association that lectures should be given in educational centers by leaders in the industry it is interesting to note that the National Electric Light Association has a committee on relations with educational institutions of which John F. Gilchrist, vice-president Commonwealth Edison Company, Chicago, is chairman. This committee has just announced the plan of its work for the coming year and has appointed four sub-committees on lectures, employment of graduates and undergraduates, courses and curriculums, and supplying information to economic departments, respectively. Each of these sub-committees is under the chairmanship of a prominent educator and the vice-chairmanship of a prominent electric lighting company executive. The membership of the sub-committees is made up of men conspicuously identified with lighting and educational interests.

The Peoria (Ill.) Railway has been appealing to the public and especially to lady passengers to observe carefully the right and the wrong ways of leaving a car. An advertisement is being carried in the Peoria papers showing two women leaving a car, one of whom steps in the direction the car is moving and alights in safety, while the second woman steps in the opposite direction to the motion of the car and falls into the street.

Signal Maintenance on the New York Subway

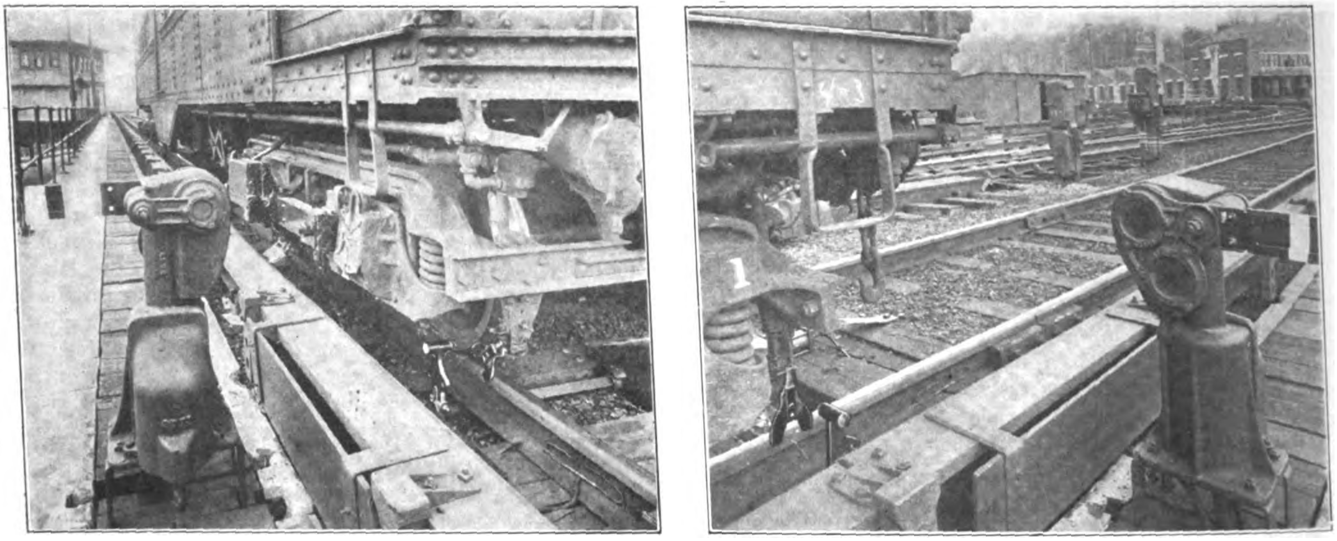
The Methods and Organization of the Signal Maintenance Department of This High-Speed Rapid Transit Line are Described in Detail and Statistics Covering the Number of Signal Failures on the Line are Given

The automatic block signals on the New York Subway, which is operated by the Interborough Rapid Transit Company, undoubtedly exercise a more potent influence on traffic than those of any other railway system in the world. A practically unlimited number of additional trains could be filled with passengers if they could be operated upon the line, but there is no possibility for the installation of additional tracks. In consequence, an extraordinary premium is placed upon any means whereby traffic can be accelerated, and the subway is now handling actually twice the traffic for which it was originally designed. The large part that signals have played in accomplishing this result may be judged by the fact that the rush-hour train headway has been reduced from 124 seconds to 100 seconds. In addition it should be noted that since the subway was built more than 2,000,000,000 passengers have been carried without a single serious collision between trains.

The signal installation by which this extraordinary result has been accomplished consists of 1233 automatic block signals, of which the majority are of the light-signal type owing to the fact that they are installed in the covered section of the subway tube. In addition there are 561 automatic stops of the mechanical trip type, one of these being placed at every main-line signal mast. All of these signals are controlled by a single-rail-return track-circuit system which was installed in 1903 by the Union Switch & Signal Company. Naturally the organization by which this apparatus is maintained is of unusual importance, especially in view of the fact that on account of the short headway any delay causes a blockade of serious proportions.

In general the signal department is made up of two organizations that report to the signal engineer, J. M. Waldron, one of them having to do only with the construction of new work and the other being responsible for the maintenance and operation of all signals, automatic stops, transformers, motor-generators, storage batteries, air compressors, signal wiring and interlocking plants that are actually installed. The interlocking plants are an important feature in the general scheme of operation, as they are located not only at points where shifting movements normally take place, but also at several points along the line where crossovers are installed to provide for emergencies that require trains to be turned back before reaching a terminal.

All maintenance work is carried on by employees classed as signal maintainers and helpers, the line being divided into a series of sections, on each of which at least one man is stationed during every hour of the day. On each section is provided a cabin for the signal maintainer in charge, and these cabins are generally located at interlocking plants so that the maintainers can operate the interlocking machines in case of blockades. The cabins are usually placed on the station platforms giving the signal maintainers ready opportunity to consult with motormen of passing trains, so that they can be called upon to do emergency repair work upon any part of the subway equipment should occasion demand it.



NEW YORK SUBWAY SIGNALS—VIEW OF DWARF SIGNAL AND AUTOMATIC STOP, SHOWING AIR-BRAKE VALVE ON TRUCK BEFORE AND AFTER RUNNING BY TRACK-TRIP

METHODS OF INSPECTION

The inspections of each section by the signal maintainers to whom it is assigned are not made at any set intervals, owing to the fact that the amount of attention required at different points varies from day to day; but, in general, all apparatus is inspected at least once in every twenty-four hours. Some of the signals are, however, regularly inspected twice daily, and the prevalence of iron dust, the difficulty of pumping sewage and the requirements of track maintenance may even involve practically continuous attention to certain signals or to a certain part of the section for several days at a time. Stuck signal relays, which prevent a signal from clearing after the train which has set it has left the block, are of rare occurrence. However, the rule is in force that, in automatic territory whenever a stop signal is encountered, the train may proceed under control after a wait of one minute. In such cases the automatic stop, which would normally prevent the passage of a train, is held in clear position by the conductor, who is provided with a special key for unlocking the stop, and the train is thus enabled to pass it. After "keying by" a stop signal, if the next signal is found to show that the track ahead is clear, it is obvious that the signal passed has displayed an improper indication. In such cases the motorman gives a whistle signal when he comes into the next station where there is a signal maintainer. The signal maintainer upon receipt of the whistle signal goes back along the track until he finds the signal that is in bad order.

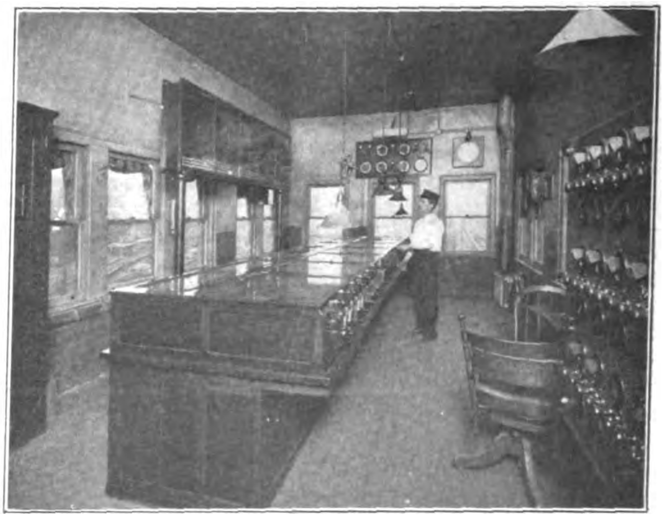
As an example of the results that can be obtained by the continual application of this close attention to the maintenance of the signals a statement of signal failures on the subway is reproduced in Table 1.

TABLE I—SIGNAL FAILURE RECORD ON NEW YORK SUBWAY

	1911-1912	1912-1913
Number of signals	1,212	1,233
Number of stops	552	561
Total	1,764	1,794
Total number of signal failures	273	173
Total number of stop failures	240	163
Total mechanism failures	513	336
Total number of signal movements	109,504,253	124,333,070
Total number of stop movements	66,683,176	70,800,273
Number of signal movements per signal failure	401,115	718,688
Number of stop movements per stop failure	277,846	434,357
Number of failures per signal per year	0.225	0.140
Number of failures per stop per year	0.435	0.291
Number of failures per mechanism per year	0.284	0.186

By this is shown that a large decrease in the number of failures of signal apparatus characterized the year 1912-1913, the fiscal year of the Interborough Rapid Transit beginning July 1 and ending June 30 of the following year. This large decrease was principally due to the work of fire protection which had been done on the signal system during the year 1911-1912. The record of over 700,000 signal movements per signal failure undoubtedly establishes a high record even for lines where intensive traffic is carried on. In the table the term "signal failure" is used in its broadest sense and is understood to mean any stoppage of a train for reasons other than that of a train in the block beyond. Cases of outside interference, such as where a bundle of newspapers is dropped from a passing train upon a track trip, and where motormen improperly report a signal out of order are, of course, not included.

NEW YORK SUBWAY SIGNALS—TRAIN STOPPED BY MAIN-LINE SIGNAL, TRACK-TRIP AT STOP IN FOREGROUND



NEW YORK SUBWAY SIGNALS—INTERIOR OF TYPICAL INTERLOCKING TOWER

An analysis of the signal failures occurring during the year 1912-1913 is also published in Table II. This divides the failures into various classes of defects and shows the number of each kind of failure that occurred during each of the twelve calendar months. It will be seen that only two of the signal failures occurring during the year were due to unknown causes. The five cases of signal failures charged to "broken or defective grid resistances" were due to defects in the resistance which is installed in series with the track relays in order to prevent the return propulsion current from passing through the relay and thus burning it out. This is necessitated by the fact that the installation is of the single insulated rail type in which the operation of the signals and the compressed-air valves for the switches and interlockers is effected by d.c. relays, the alternating current being used only for controlling the track relays and for the signal lights. The solenoid signals referred to in the table are of a home-made type in which the usual slot coil is replaced by a solenoid that operates the semaphore blade directly.

ARRANGEMENT OF MAINTENANCE FORCE

As mentioned before, each section is inspected complete every day, but as the main-line sections are ap-

proximately 1½ miles in length the difficulties of transportation are negligible. The section length of 1½ miles is maintained quite closely except in the case of certain complicated places, such as the terminals and at the points of diverging routes like the Ninety-sixth Street junction. The number of signals in each section varies approximately between forty and eighty with about half as many automatic stops, and under normal conditions three signal maintainers keep in repair all of the apparatus on each section. These three signal men, however, work in three ten-hour shifts, the attention to signals, therefore, being continuous. The ten-hour shifts are so arranged that the overlap comes during the early morning hours, because all of the heavy work is done between 1 a. m. and 7 a. m., this being the only period when the traffic is relatively light, the train headway on the local tracks being increased to 7½ minutes during this period.

At the points where interlocking plants are kept normally in continuous operation and where there are air compressors, storage batteries and transformers, each signal maintainer is provided with a helper, and it is from this force of helpers that the signal maintainers are developed. Owing to the fact that the main-line sections are of an approximately constant length and are arranged almost regardless of the number of signals, certain of the sections are considerably easier to maintain than others. On the easy sections the less experienced men are placed and they are advanced to the more difficult positions as their experience becomes extended. Ordinarily, the helpers serve in that position for about two years, after which time they are generally capable of maintaining some of the easier sections. In general, the force of helpers is recruited from construction gangs, as a certain amount of construction work is being carried on all the time.

The signal maintainers do no actual repair work to damaged parts of signal apparatus, the replacement method of field work being carried out in all cases and the maintainer being required only to make the necessary replacements and adjustments. Practically all repairs to damaged apparatus are made at a central repair shop that is located at one end of the line. Here three repair men are employed continually in rewinding coils and in doing other heavy repair work on apparatus that has been sent to the shop. In addition an extra signal maintainer is kept at work in the repair shop during normal conditions so that in case of the failure of any one of the regular signal maintainers to report for duty the spare man can be called upon to take the temporary vacancy. Practically no repair work has to be sent to the signal manufacturers, and, as shown by the number of repair shop men employed in proportion to the number of signals and automatic stops that are maintained, the repair work is normally very light.

No lightning damage has been experienced even in the case of the outlying sections of the subway that run upon an elevated structure. This unusual condition is ascribed to the fact that an iron fence is run along the entire length of the elevated structure and is grounded to the steel framing.

A plan has been formed to construct new carshops in south Russia, and negotiations are going on for the organization of a stock company. The originator of the plan is said to be a well-known banker and manufacturer. It has been reported that the manager of the Compagnie Centrale de Construction Haine-St. Pierre, the largest car and locomotive works in Belgium, has gone to south Russia to determine the location of the proposed works.

COMMUNICATIONS

Operation Without Train Orders

THE SOUTHWESTERN ELECTRICAL & GAS ASSOCIATION
DALLAS, TEX., Oct. 10, 1914.

To the Editors:

Referring to the article in the Oct. 3 issue of the ELECTRIC RAILWAY JOURNAL entitled "A New Method of Traffic Acceleration" and to your editorial on the same subject, the writer operated one of the early interurbans twenty years ago and introduced somewhat the same plan as that used by the Scranton & Binghamton railroad. On this line the question of operating under signals or under train orders was discussed, and while the signals of that time were rather crude, cumbersome and somewhat unreliable, they seemed, in conjunction with the time-card and a delay-time-limit, strictly enforced, to be able to eliminate a great deal of waste time, and would also tend to increase vigilance and accuracy on the part of the trainmen.

The interurban road was about 15 miles long, and very often it ran trains of two cars, having at times heavy rush traffic. It was divided into six signal sections, approximately equal in length, but some allowance was made on certain sections for the delaying action of curves and grades and the sections were really divided more by a question of time than by exact distance. The trainmen were made to equip themselves with standard watches, which were inspected weekly and compared with a standard clock at the starting point at the office on every trip, and they were thoroughly trained in the observance of the delay-time-limit principle.

The practice was that a car, on time at a regular passing point, waited for a scheduled meet for the length of time that it would take the opposing car to run from the turnout in advance. It then started on its way with caution, that is to say, at danger points, such as curves or where the meeting car could not be seen at a fair distance, the car was brought under control for immediate stop. Signals were accepted at their face value and the signal system was so arranged that any failure on its part to act resulted in a caution indication. No stop signal was instituted, the signals showed either that the block was certainly clear in front or that it supposedly was not. In the former case the signal governed, in the latter case the delay-time-limit governed.

Where a car broke down between turnouts, say centrally between them, there was a certain amount of delay, but as each car on both sides of that broken-down car followed the same rules, the final result was that they soon came up on each side of it, transferred their passengers around it and from it and returned on the schedule time of the next, or succeeding car.

Every car or train going over the road had its train number and each motorman was daily furnished with a group of printed cards giving the scheduled time of arrival and departure, at termini and at each turnout, of every car or train on the schedule for the day, and in case of a break-down certain of the interurban cars would temporarily lose their train place so far as the schedule was concerned. Every car had on the front of it, on the left side, a plate carrying its train number for the day, the plate being illuminated at night. On regular schedule, with no accidents or delays, every motorman knew the number of the train that should meet him at each turnout, and the instructions to motormen were that, when they met with a car or train carrying some other train number than that which should be at the turnout under normal schedule, immediate inquiry should be made and information given by the other car crew as to the reason for this. This tended to make the man who was on schedule time more careful, as he was then informed that the regular schedule was broken and that extra caution was necessary and, also, that extra exertion was desired so that the regular schedule might be again resumed as quickly as possible.

These orders and operations, in conjunction with the block signals, allowed the road to be operated at what was, at that time, a very high speed, that is to say, with some six or eight stops the cars averaged over 30 m.p.h. with some heavy grades and some curves of small radius. During one year's operation of this road, with very heavy traffic, there was only one collision, and that was caused by absolute wilful disregard of the rules.

It is surprising even on a road of considerable length and many passing points, how soon the trainmen become habituated to the system if proper supervision is given and the watches strictly checked. There is also an astonishing amount of time saved by this system over that of train orders, especially on rush days. The writer has, since that time, operated roads under the dispatcher system simply because that system had been installed from the beginning, everyone was used to it and it seemed unwise or undesirable to change it. But in starting to operate a new road of this character it should most decidedly be operated entirely by block signals and proper delay and cautionary rules. With the same check and supervision given to each one, the chances of accident are greater with the dispatcher system than with the other, and there is very much less delay and a better opportunity to straighten out the schedule when it becomes temporarily disorganized.

It may be that, under the best arrangement of the block system, more turnouts will be necessary than with the dispatcher system, but this is a matter in which the original cost and maintenance may be definitely fixed and known, whereas the added risk and the delay consequent upon the dispatcher system is an unknown quantity. There may, also, be interurban lines so situated that they are compelled to depend upon individual dispatching, but in a trip made a few years ago over most of the high-speed electric interurban roads in the country, with this particular point in view among others, the conclusion of the writer was that there was not one of all the roads visited in which schedule and safety could not be bettered by abolishing the dispatcher, as a dispatcher, and leaving him merely as a "trouble man" who could be communicated with at every turnout but who, except under extraordinary conditions —provided for in the rules—would not interfere with the movements of the cars, or with the schedule for the day.

It should be said that only a very few rules are needed to cover such a system for the reason that these rules need only govern the contingencies. Once the men are trained into the principle of the system, ordinary operation goes on like clockwork and the new men absorb the idea, by practice, in a very short time. It is being more and more appreciated that the human element is a vital factor in producing both safety of operation and perfection of schedule, and that the nearer the trainmen approach the condition of automatons or dummies the less the good results, as a whole. While, under the signal and delay-time-limit system there are rigid rules that are concerned mostly with absolute safety of operation, yet the matter of maintenance and resumption of schedule after delay or accident is largely in the hands of the trainmen.

The writer has not given this matter much attention the last few years and really was not aware that so little had been done in the line which the Scranton & Binghamton has taken up. He is not very well acquainted with the latest modern systems of block signaling, but from what he has read and observed it should certainly be much more easy and more safe to operate at this time with the improved and more reliable signal systems, than it was twenty years ago with the rather crude and imperfect systems that were then in use.

H. S. COOPER.

ILLINOIS TRACTION SYSTEM

SPRINGFIELD, ILL., Oct. 10, 1914.

To the Editors:

We have read your description of train operation on the Scranton & Binghamton Railroad and your editorial commenting on it in the issue of Oct. 3. This is particularly of interest because we have 175 miles of interurban equipped with track-circuit-controlled automatic block signals of the semaphore type.

We note that movements of trains on the Scranton & Binghamton road are governed entirely by signal indications, and that trains are operated regardless of time-card meeting points and are not under the jurisdiction or handling of a train dispatcher. You have evidently given but a small part of the requirements or duties of the train crews or the method of operation. What happens when a signal or signals are not in operative condition? It appears to me that, in the absence of a train dispatcher, this would create a situation of too much importance to be covered by operating rules or left to the judgment of the trainmen. We note that sidings average 1 mile apart, which requires an approximate running time of three minutes from one to the other, and that there cannot be delay of more than three minutes to any train.

We admire block signals not only for the increased safety they afford but, in addition to this, for the increased confidence which they give to the trainmen, especially in bad weather. In consequence, we think that you are unduly severe when you state that block signals hinder rather than accelerate interurban high-speed traffic and that they comprise merely a safeguard superimposed upon the structure of operating rules. We operate hourly service through signaled territory and we are very frank in saying that the installation of the signals did not in any way hinder operation. On the contrary, we feel that operation has been helped and that it is easier to keep our trains on time since the installation of the signals. In connection with this, however, it should be said that the performance of our block signal is practically perfect, showing a percentage of 99.97 perfect operation. We note your query whether high-speed interurban roads can take full advantage of signal equipment unless they accept signal indications at their face value and run on signals rather than orders, but we are not able to see how the high-speed interurban lines of the north central states, which are now equipped with signals, could operate in the manner which you suggest. The procedure involved in changing the method of operation to provide for the acceptance of signal indications at their face value so that trains can proceed in accordance with signal indications regardless of time-card meeting points is a situation confronted by many physical obstacles on our property and also, I think, on every other high-speed interurban line in the Central States.

Some of the things which I believe absolutely necessary of attainment before this method of operation could ever be considered for our lines include the following: The continuous track circuit would have to be extended from one end of the road to the other, exceptionally thorough inspection of the signal system would be necessary, siding locations would have to be adjusted, time-card would have to be laid out for the new scheme of operation, and trainmen would have to be educated and trained with that end in view.

Not being familiar with all of the existing operating rules of the Scranton & Binghamton Railroad we do not feel capable of making a statement as to the success or failure of the operation of that road on signals alone, yet we do feel that, after all of the things that have above been enumerated have been done, we would not want to undertake the operation of our road through its signaled territory depending on the signals alone to govern the movement of trains. We believe that we would prefer to give the train movements close supervision, provide the best of inspection for equipment, and control the movement of the trains by train dispatcher rather than to undertake and be responsible for operations depending wholly upon block signals. We are basing our opinion in this regard upon the fact that automatic signals have been known to give clear indications when they should give stop indications, and, with service as frequent as every fifteen minutes and trains operating under block signal control, you can readily see what a false clear indication would mean. You can also see what a bad order signal would mean without telephone communication or control of movement by train dispatcher.

Please understand we are not criticising the operation of the Scranton & Binghamton Railroad as a railroad. We are taking exception only to your statement that high-speed interurban roads should take advantage of signal equipment by running their trains under signal control alone, and in doing this we are giving our opinions so that more may be brought out about the real operation of this road which is depending entirely upon its signals for train movements.

C. F. HANDSHY, Assistant General Manager.

Insert Special Work Failures

UNION TRACTION COMPANY OF INDIANA
ANDERSON, IND., Oct. 16, 1914.

To the Editors:

In reading the various articles that have appeared in the ELECTRIC RAILWAY JOURNAL on the subject of insert special work it has seemed to me that what I might write would be simply a repetition to a considerable extent of what has already been written, and a good many of the points discussed are what engineers, or at least some of them, have known for some time. On the other hand, to further this work, I want to add these remarks:

Concerning insert special work, I believe that the construction giving the longest life is that having the machined bed as a bearing. I find that spelter eventually will come out, although I have some frogs that have been in service for seven or eight years where the spelter has come out around the sides but the insert is not yet loose. Of course at these points the traffic has not been as heavy nor the wheelage as great as it has at some other points. The completely machined-fit, bolted-down type appears to be giving the best service and the longest life.

It is folly to expect that any kind of an insert will last forever. The raising of flangeways, for instance, I do not think is going to increase indefinitely the life of a frog or a mate, but I think it is a step toward lengthening the life. All of the photographs that have appeared in the articles showing the floors of frogs and mates cut down by flangewear, are simply the result of natural wear, since these flanges riding on the throatway floors will evidently wear out the material, no matter what it is. On the other hand, I believe we are getting better manganese from the manufacturers now than we did a few years ago. They have learned about the manufacture of this material as well as the engineers have about the use of it.

The cause of inserts becoming loose, I believe, is nothing more nor less than the rolling of the wheels over these inserts. Inasmuch as they are not a part of the casting, the vibration and the impact, due to the wheels, gradually loosens the insert from the material which is holding it in place. The nearer you can bind the insert to the casting itself, or approach making the insert a part of the casting by providing machined bearings and bolts which transmit the stress through the bearings, the better will this insert resist impact and remain firm. Whether or not a solid manganese piece is warranted, I believe depends upon the special conditions of traffic in any given city. I do not believe that with us the expenditure is warranted, but in other cities with more frequent service and greater wheelage, it might be found to be economical to use solid manganese frogs and mates.

With reference to the loose arms in cast-iron bound work, some manufacturers, I believe, make the rail arm in the casting too short. On the other hand, if the joint at the end of the arm hasn't the proper support, it is liable to break. I have never had a frog arm break outside of the casting, but I have had a good many of them come loose in the casting. This leads me to believe that the bond between the rail and the casting is not what it should be. Moreover, we cannot always get first-class joints at the end of the arm in special work, any more than we can at other places, so that a certain factor of safety must be added to the grip area to improve the bond for these contingencies.

L. A. MITCHELL, Superintendent of Roadway.

Effect of Car Wheel Diameter on Motors

LEWISTON, AUGUSTA & WATERVILLE STREET RAILWAY
LEWISTON, MAINE, Oct. 9, 1914.

To the Editors:

I have read with interest the article by H. J. Parks in the ELECTRIC RAILWAY JOURNAL of Oct. 3, 1914, on the "Effect of Car Wheel Diameter on Motors," but do not fully agree with him regarding this effect. As the speed of a railway motor is governed by the load it is carrying, I do not believe that the difference of ¼ in. in the diameter of the wheels on a two or four-motor equipment will make any material difference in the load on the motors. I have made numerous tests in the past few years and have failed to find any difference in the temperature of the motors operating on axles with different size wheels.

With cars on which cast-iron wheels are used, it frequently becomes necessary to change a pair of wheels which are not entirely worn out; and if new wheels are installed the difference in diameter is sure to be ½ in. or more. In these cases I have made tests with the results stated. I have had under my observation cars operating with steel wheels with 33-in. diameter when new. It became necessary to change one pair of these wheels on account of flange wear when the diameter was reduced to 32¼ in. A new pair of wheels was installed, but careful tests failed to show any noticeable difference in the temperature of the motors. I have also had installed under the same conditions turned wheels which were 1⅛ in. smaller than the other three pair, and I still failed to find any difference in the temperature of motors. I do not, however, recommend operating wheels with such a difference in diameter.

When making these tests the motors on several cars operating under the same conditions should be tested in order to make a fair comparison, as many complications might arise to cause the overheating of a particular motor or set of motors. I should like very much to hear from other experienced men on this subject, as I believe it is a benefit to exchange ideas.

C. H. NOTTAGE, Master Mechanic.

OHIO ELECTRIC RAILWAY
COLUMBUS, OHIO, Oct. 10, 1914.

To the Editors:

I feel that I must challenge the statement of brother Parks from East St. Louis in your Oct. 3 issue, page 623, where he writes that a difference of ¼ in. in the diameter of his car wheels caused two armatures to burn out.

I do not question the sincerity of Mr. Parks nor the accuracy of his statement of fact, but I cannot agree with his conclusions. It is possible that this is a typographical error and that 1¼ in. was meant, in which case I would be inclined to think Mr. Parks had some grounds for his belief that this was the cause of the burn-outs.

This question of the effect of different diameters of wheels on motor load has been one of great interest to me for some years, and I have been hoping for some time that someone would come forward with a demonstration. That a difference in the diameter of the wheels on the same car will cause unequal loading of the motors is an accepted fact, but just how much this is I have never been able to find out. I have even appealed to the experts of one of the best-known companies making railway motors and equipment for a solution of this problem, but received only an evasive answer.

On the property that I represent it is a rule to keep the diameter of wheels on any car within 1 in. of each other, but cases have been known where we have found wheels differing as much as 2 in. In one particular case a careful test of temperature rise was made on motors on a car with wheels differing by more than 2 in. While a difference of temperature rise was shown, the expert making the test could not say how much of this was due to the difference in diameter and how much to other causes, such as different ventilation, etc.

Mr. Parks does not give the diameter of the wheels used, so that it is impossible to compute the percentage of difference, but assuming that his wheels were only 30 in. in diameter, which is about the limit for city cars, we would get for ¼ in. a difference of 0.8 per cent in diameter, which I cannot by any stretch of imagination conceive as the cause of the armature burn-outs.

There is one fact that possibly may not be well known in this connection, namely, that on interurban cars, or cars that run at fair speed, the rear motor of a four-motor equipment will always show the greatest temperature rise. For this reason, if it is necessary to use wheels of different diameters, the longer wheels should be placed in the front end of car and the small ones at the rear so that the motor doing the most work will have the best ventilation.

This subject is of great interest to me and I believe that a practical solution would be of great value, since if we know about what the effect of different diameters is we will be in position to decide how much expense will be justified in keeping the diameters of wheels within certain limits.

This communication has not been written in a spirit of criticism, but rather in the hope that it will bring out discussion and further facts.

F. J. FOOTE, Master Mechanic.

ASSOCIATION NEWS

PUBLIC SERVICE COMPANY SECTION MEETING

At the meeting of the Public Service Company Section of the association, held in Newark, N. J., on Oct. 29, papers were delivered by W. J. Clark, manager heavy traction department General Electric Company, and Martin Schreiber, engineer maintenance of way Public Service Railway. Mr. Clark spoke on "European Public Utility Conditions" and gave a wealth of data showing the comparative results of public and private operation and ownership of utilities in Europe and the United States. His paper was illustrated with numerous charts projected on the screen. Mr. Schreiber described in considerable detail, with the aid of lantern slides, the plans of the Newark terminal, now under construction. He traced the development of the enterprise from its inception less than two years ago and concluded by showing interesting progress pictures of construction. He stated that at the present time a considerable proportion of the caissons for the column footings have been sunk. The operation of sinking the caissons was explained with the aid of a diagram prepared especially for the purpose and adding materially to the value of the paper.

After the addresses the annual election of officers of the section was held and the following were unanimously elected: President, P. F. Maguire, chief clerk maintenance of way department; vice-president, W. R. Ricker, shop foreman mechanical department; secretary, A. T. Warner, traffic investigator transportation department; treasurer, D. H. Roszel, division engineer engineering department; director (one-year term), Thomas Leahey, general foreman distribution department; director (two-year term), George L. Walsh, claim agent Passaic division.

DENVER TRAMWAY COMPANY SECTION NOTES

The Denver Tramway Company Section is now entering upon its third year of work, having been organized Sept. 19, 1912, with a charter membership of forty-eight. The meetings are held in a fine auditorium with a seating capacity of 500, provided by the company at the company's building in Denver.

The opening meeting of the current year was mentioned in the issue of the ELECTRIC RAILWAY JOURNAL for Oct. 10. At this meeting, which was devoted to safety matters, the value of section work was illustrated most effectively. The section first heard an account of the safety work of the Union Pacific Railroad. It was learned that during the preceding two years 3000 recommendations were received by the safety bureau of that company from employees, and 90 per cent of these recommendations were acted upon favorably. The discussion of local problems under the lead of Vice-President John A. Beeler brought out clearly how strenuously the Tramway Company is endeavoring to reduce the number of accidents. An effort was made to connect the accident efficiency of the men with their coasting records, recording fare-register records, etc., but it was found that valuable as these and other mechanical devices are the personal element remains the controlling factor. Mr. Beeler said that the Denver Tramway was the first company in the United States to adopt the center-entrance car and was one of the first to adopt the automotoneer, the straight air brake with emergency feature and other devices. He pointed out a record on one line of 54,000 car-miles per accident, including those of the most trivial character, and stated that a record of 100,000 car-miles would soon be reached. He also showed how proper training with the coasting recorder can produce remarkable results. H. G. Munkhenk is the secretary of the section.

among the employees when more than 10 per cent of the whole; the location, construction and sanitary condition of the plant; the provisions and equipment for treating accidents and illness at the plant; the examinations given to an employee before and after beginning service, the amount of welfare work done, the average salary per year, the proportion of employees having a yearly vacation with continuance of salary during that time, the working hours, the maximum and minimum ages of employees, and special hazards in the business.

OTHER SYSTEMS

The group insurance plan has also been adopted by the Aetna Life Insurance Company, the New York Life Insurance Company, the Metropolitan Life Insurance Company and the Connecticut General Life Insurance Company. The activities of these companies have been entirely along industrial lines, however, no policies being written for electric railways. Hence what provisions these companies would make for group insurance on electric railways could only be determined by an examination of individual groups.

Objections to Government Ownership

Address by W. J. Clark Before New England Street Railway Club Last Week

Government ownership was the subject of the evening at the regular monthly meeting of the New England Street Railway Club at the American House, Boston, on Oct. 22, the speaker being W. J. Clark, manager of the heavy electric traction department General Electric Company, New York. President John T. Conway occupied the chair and a large and enthusiastic audience listened to the reading of the paper, which is abstracted below:

The greatest possible value which can be derived from electric railway organizations is to so qualify their members that they at all times can intelligently, diplomatically and yet militantly set forth as quasi-public servants and as good citizens the maximums of economic truth on public utility questions. A moral obligation rests upon us to impart to the public the results of our experience obtained in its service. No one can foretell how soon it will become impossible to cause the masses of the people to think straight on public utility issues, until they have later on paid the penalties of government ownership, toward which they have secured a long start through improper leadership and misunderstanding. This agitation is very much alive and presents perhaps the most important economic problem confronting America to-day. The inauguration of public ownership would be an economic calamity to the entire country and to all citizens not so fortunate as to secure highly remunerative positions at public expense. It is most important to avoid establishing a precedent in the realization of this propaganda. Immediate danger confronts the industry, as the executives of two extensive systems have in a preliminary way been forced to cooperate with those favoring municipal ownership, in the working out of plans under which their properties may be taken over by the cities in which they are located. Sooner or later any or all of us may be forced into a like position when we can no longer consistently advise the public as to its real interests. If we do not enlighten the public, a portion at least of the responsibility is ours.

It is the duty of the industry to dispense the gospel of economic truth. There is scarcely a street railway in the country which has not been forced through unjust public pressure to make far greater capital investments, betterments and unprofitable extensions than were ever contemplated. The establishment of a flat 5-cent fare was a financial blunder from which the public has profited enormously. The monetary benefits of street railways to the public cannot be estimated, and these have been reaped without the slightest financial burdens being imposed upon the latter. There are those who would withhold from the companies the benefits of those increases in real estate and similar values which have been created by their operations alone. There is no such thing as an "unearned increment," for every increase in value is produced by human effort.

In every form of public utility effort America surpasses all other countries. Taking into consideration the comparative prices of labor, the initial cost of such facilities and the services rendered, the cost to the public is lower here than anywhere else. Wherever government ownership has been extensively undertaken the results have been unsatisfactory, fundamentally because of legislative methods and practice, which virtually prevent publicly owned enterprises being gaged by the same standards as economically owned undertakings of a similar character. The recent Congressional legislation for government railroads in Alaska exempts the roads from complying with the Interstate Commerce Commission's system of accounts. Experience with state-owned railroads in Pennsylvania and with state-owned canals in New York is most illuminating to the opponent of government ownership, which should be vigorously opposed in the interests of both public and private welfare.

Pamphlet on Needs of Latin-American Countries

A pamphlet giving the statements made by representatives of Latin-American countries at a trade conference with American bankers and business men in Washington recently, has been issued by the Bureau of Foreign and Domestic Commerce and is available for general distribution. The conference was called by the Secretary of State and the Secretary of Commerce to obtain a clear statement of the commercial needs of both the United States and the Latin-American countries and the facilities for co-operation in supplying those needs. The statements made by the Latin-American representatives set forth the conditions in their respective countries and the particulars in which the assistance of interests in the United States is desired. The opening statement by William Jennings Bryan, Secretary of State, and an address by William C. Redfield, Secretary of Commerce, are also included. The pamphlet may be obtained from the superintendent of documents, Government Printing Office, Washington, D. C., for 5 cents.

Dangers of Boycott in England

In England, since the beginning of the war, retaliatory measures have been suggested against local German-owned concerns. Recently, according to *Engineering*, a letter signed by twelve trade unionists in the employ of Siemens Brothers Dynamo Works has been sent to the press calling attention to the fact that 2000 men are engaged at the works, of whom only 4 per cent are foreigners, and not all these are Germans. If, as has been suggested, there should be a boycott of the firm these 2000 men would suffer an immediate loss of work. The town of Stafford would feel the withdrawal of some $500,000 a year now paid in wages, and for this there could be no compensation to be found in migration. The firm of Siemens Brothers, of which the Stafford firm is an off-shoot, was founded in 1847 by William Siemens.

Claim Agents' Papers and Discussions

Abstracts of Papers Presented at the Recent Atlantic City Convention of the American Electric Railway Claims Association, Together with Digests of the Printed Discussions on the Same Topics

The American Electric Railway Claims Association has just released for publication the papers and printed discussions thereon presented at the recent convention in Atlantic City, Oct. 12-16. These are in addition to the running reports of the association proceedings published in the ELECTRIC RAILWAY JOURNAL daily issues of Oct. 14, 15 and 16. Abstracts of these papers and discussions are published below.

LEGAL CONDUCT OF INVESTIGATIONS

BY E. P. WALSH, ATTORNEY UNITED RAILWAYS OF ST. LOUIS, ST. LOUIS, MO.

The foundation for a claim for damages and a suit at law is laid the moment an accident occurs. The foundation for a successful defense, if such is possible, against a claim for damages and a suit at law may also be laid at the same time if the trainmen intelligently and alertly obtain the names of the injured and of witnesses most favorably located to see what actually occurred, and also if the trainmen calmly exercise their powers of observation in order that they may afterwards relate intelligently all details of the accident. The success with which this work is done depends in great measure upon the ability of the employing officer to select proper material for trainmen and upon the instruction and training later given.

Under normal conditions, with the accident reported and the names of witnesses secured, it becomes the task of the claim department to handle the matter in the most efficacious way. If the accident is one where liability is certain, the necessity of speedy adjustment is readily apparent. The greater the delay the more danger there is of an exaggerated idea of the injuries as well as of the demands to be made. Yet from a legal standpoint it is not always safe to urge a speedy settlement for a serious accident, for the courts sometimes inquire carefully into such contracts because of the possibie inability of the injured person to comprehend fully the extent of the injury.

During the necessary interval between injury and settlement, however, whether long or short, the claim department must make an effort to ascertain all pertinent facts in connection with the accident and the injured person, such as the identity of the attending physician and facts concerning the claimant's business, his social and even his religious associations. At the outset a statement should be secured from the claimant as to the physical details of the accident, the extent of the injury itself, the previous suffering of similar or other injuries, prior claims against the company concerned or others, and the carrying of accident or liability insurance. This statement should be signed by the claimant and if possible attested before a notary public. It is desirable in large companies to have directly attached to the claim department several men possessing notary public commissions to do work of this kind.

The claimant should be examined at the earliest possible moment by the company's surgeon. If the claimant's doctor will not extend courtesies of this character or is forbidden to do so by the claimant, there is reason for suspecting the motives of both doctor and patient. The claim department must then try by its own efforts to ascertain the true situation. It is often better to risk a law suit and rely upon the time necessary to bring it to trial as giving opportunity for a more complete investigation. If it has not been possible to secure a medical examination of the claimant prior to the filing of the suit, a request should then be made as early as possible that the court compel the plaintiff to submit to an examination by some disinterested physician appointed by it. From this the defendant can determine whether it is desirable to adjust the claim or proceed with the trial.

As soon as suit is filed the plaintiff's deposition should be taken by a lawyer experienced in damage suits and not by young lawyers recently graduated from school. Depositions taken by the latter frequently contain nothing enlightening, although in importance they are equal, if not superior, to the actual cross-examinations of plaintiffs.

The particular methods the claim agent will pursue rest largely with the individual claim agent and his facilities. Expert investigators, however, should be trained for all branches of the work within the department itself, especially in companies in large cities, because their efforts are more efficacious, if later it is necessary to put them upon the witness stand, than if they were employed by agencies entirely separate from the claim department.

Within a reasonably short time after a serious accident in which a contest is apprehended, the motorman and conductor should be sent to the claim department and a very careful and comprehensive statement should be taken, acknowledged and signed before a notary public. The reported witnesses should be interviewed, their signed statements in writing taken, and, if possible, their affidavits secured. Efforts should be made to ascertain if they know witnesses whose names were not secured by the trainmen, for excellent witnesses for the defense are thus sometimes brought to light.

Employees as witnesses, in their desire to combat the attacks of opposing counsel on cross-examination, are quite likely to undo all the good work accomplished. Hence they should understand that their sole duty is to answer truthfully the questions asked. They should be reasoned with as to speed and distances, for their powers of observation are so undeveloped that if called upon suddenly to explain operating points they cannot do so with any degree of particularity. The lawyer, therefore, should be familiar with the operation of a car and the conditions accompanying the accident, and, in talking to the men before the trial, should be able to elicit from them all the facts and at the same time instill into their minds an ability to relate those facts so that the jurors may have a correct picture of the entire occurrence.

In large cities a police officer is usually present very shortly after an accident occurs and generally secures the names of the witnesses. Written and signed statements should be taken as early as possible from the witnesses whose names appear upon the police report, because this becomes public property and is generally the first source of information consulted by the "ambulance chaser." If the defense anticipates these men, there is some likelihood that a fair and impartial statement will be given.

In cases of apparently fraudulent or exaggerated claims, any sort of espionage that furnishes information as to the claimant's conduct and mode of living is valuable in determining what should be done by way of adjustment, but such espionage to be of value in the trial must be so conducted that its results can be shown to the jury. For instance, a system of photography has been used with splendid results, because at the trial pictures were shown of the claimant actively engaged in business or pleasure at times when his testimony declared him to be in bed or crippled.

The knowledge that a claimant has or has had accident or liability insurance is important as enabling the claim department to ascertain the extent of injury claimed under that policy and also to learn whether or not the company has a history of previous accidents. In this connection the index bureau is one of the most valuable sources of information, and it is to be regretted that all companies have not taken advantage of it.

The adjustment and defense of damage claims are becoming more strenuous propositions every day, as well as more expensive. The work reduces itself to a play of wits between the claimant and the claim agent, and the latter is often made a victim of unscrupulous, malingering fakirs and dishonest lawyers and doctors. A claim agent is hardly to blame if at times in repelling such assaults he meets fire with fire. The adjustment of the claim of the honest claimant is a simple proposition, but the quack, the fraud and the pettifogger cause the real troubles of the claim agent.

DISCUSSION BY MR. HOFFMAN

L. S. Hoffman, general attorney Public Service Railway, Newark, N. J., agreed with Mr. Walsh that the ability of an employee to discover flaws in the foundation of the lawsuit goes back to his selection by the employing officer. At the same time good work can be, and is, accomplished by calling to the attention of employees of average intelligence the great importance of obtaining all possible information before leaving the scene of an accident. It is particularly important to locate the exact spot and, if feasible, to call it to the notice of disinterested witnesses.

In Mr. Hoffman's opinion, the mere fact that the injured party does not comprehend the full extent of his injuries does not prevent the meeting of the minds of the parties so as to make a binding contract. Yet, if a physician employed by the defendant should either mistakenly or wilfully underrate the present extent of the injury, or disparage the future results, there would be ground for setting aside a release. A release would also be set aside where there was a mutual mistake of an actually existing fact, but a mistaken opinion as to the outcome of a known injury forms no ground for setting aside a release.

The usual excuse given when signed statements contain matter materially different from the testimony given in court is that they were signed without being read. In order to close this gap the Public Service Railway has adopted a practice of asking the signer of a paper to write above his signature, "I have read the above statement and it is correct," or words to a similar effect. Witnesses are usually quite willing to do this.

Mr. Hoffman called attention to one danger in taking depositions before trial. When the plaintiff's deposition is taken by the defendant, the defendant makes the plaintiff its witness, the result being that the plaintiff's lawyer has a right to cross-examine his client. The advantage of such a cross-examination to the plaintiff outweighs the advantage to be gained from the deposition by the defendant. In New Jersey the practice is to serve the plaintiff with interrogatories covering matters pertaining to the defense and sometimes a bill of particulars is also demanded, so that considerable information is secured which could have been obtained by taking the deposition of the claimant.

Mr. Hoffman said that his company very seldom used any secret service investigators except occasionally in criminal matters, but he considered the results of secret investigations very often important when used for the purpose of cross-examination. As to the advisability of having the court compel the plaintiff to submit to a physical examination by some disinterested physician appointed by the court, he deemed such a course of procedure not by any means satisfactory. When the claimant will not submit to a physical examination, there is usually something crooked about his claim, and a physician who is not accustomed to making physical examinations of claimants in accident cases is no match for a malingering claimant backed by the instructions of his physician and his attorney. The only proper physician to examine an unwilling claimant is an expert who, through experience, knows all the tests to be applied to determine malingering. Much depends upon the practice of the court, however, in appointing experienced men, and this can be known only through experience. It is often efficacious to bring out at the trial the request and the refusal for a physical examination, and follow this up by making a motion that the plaintiff submit himself then and there to a physical examination by a physician of the company's selection who is present. Very few attorneys dare risk refusing such a request because it would prejudice their case before the jury.

DISCUSSION BY MR. MUIR

According to Wallace Muir, assistant counsel Kentucky Traction & Terminal Company, Lexington, Ky., it is difficult to distinguish between investigating an accident from the standpoint of defense and investigating the same from the standpoint of adjustment. The object of investigating an accident is to determine legal liability. In order to determine this, the facts under which the person, or property, was injured must be fully and truthfully obtained, after which the law determines the question of responsibility and liability. Ordinarily no case should be adjusted where the company is not legally responsible for the injury inflicted, and when a case is once prepared so that a proper conclusion may be reached for the purpose of adjustment, the case should be in such a condition that it can be filed away and be ready for trial with but little additional work. In other words, preparation for adjustment is preparation for defense.

Mr. Muir drew one distinction, however, between preparation for adjustment and for defense. In adjustment the location of the accident is familiar to those concerned. In a trial before a jury all the jurors are not familiar with the surroundings, such as the character and grade of the street, its width, the position of the car tracks and the character of the car. Often it is essential that these points be brought out forcefully to a jury by photographs, diagrams and miniature constructions, and in some cases the jury may be taken to view the place of accident.

Mr. Muir emphasized the need of tact in trying to secure signed statements. The securing of a signed statement from the injured while in pain or in a semi-conscious condition is of little benefit and often dangerous. The statement of a child, although bright and intelligent, should be taken in the presence of its parents, one of kin or someone closely connected with the injured. The investigator should have each person giving a statement read it over in the presence of another, the third party to witness the signature unless it is sworn to. It is not an advantage, however, as Mr. Walsh says, to have a statement sworn to before a notary public who is a claim agent or investigator of the company. The claim agent and investigator, as far as possible, should be kept in the background at the trial, for a verdict is often rendered against a company solely upon the ground of some supposed misconduct on the part of the claim agent.

In a certain character of accidents, such as when there is no question as to liability, it is very essential to see the injured as soon as possible and effect compromise. Every courtesy and attention should be extended to the injured party, frequent visits being made without any talk of compromise until the proper time arrives. The question of compromise or the merits of the case should not be discussed in the presence of any disinterested person, for in nearly every case the outsider is the one who puts the extravagant figure in the mind of the injured.

CLAIMS DEPARTMENT POLICIES AND PRINCIPLES

BY CECIL G. RICE, SUPERINTENDENT CLAIMS DEPARTMENT
PITTSBURGH RAILWAYS, PITTSBURGH, PA.

Upon my entrance into the claim business I was not particularly impressed with the attitude of the public toward the ordinary claim agent, but I concluded that something could be done to change this opinion of the public, through imitation, through trial and error or through reasoning. Not knowing where to find the thing I desired to imitate, I started by trial and error and finally took up the reasoning process. From scientific management and business efficiency, I realized there were five things to do: First, to investigate and standardize; second, to form an organization that would carry these standards into effect; third, to get the men to form the organization; fourth, to provide proper compensation for the men, and fifth, to get a relay of men so that when one left the vacancy could be filled immediately.

We changed the department into five separate and distinct bureaus—clerical, investigation, adjustment, medical and litigation. Each of these bureaus was put in charge of a chief, who was responsible for the work. When an accident occurs it is reported to the claim department and goes to each of the bureaus with the exception of the litigation bureau. This bureau has absolutely nothing to do with the adjustment of a claim. The investigation bureau is charged with getting the facts, whether favorable or unfavorable. The clerical bureau has to do with the records. The medical bureau is charged with learning the facts from a medical viewpoint and making and arranging examinations. The adjustment bureau takes care of the actual adjustment after the clerical bureau has made its records. If, after all the facts have been filed, an adjustment is not possible and suit is entered, the papers are turned over to the litigation bureau for the purpose of preparing a defense or making a settlement.

Every Saturday afternoon the different chiefs meet with myself for discussion. Each of these chiefs should know as much about all the departments as the superintendent. Once a month there is a meeting of all of the members of the departments with papers or discussions. Once a week each bureau has a meeting to talk over the details of its work. In this way every man in the department is supposed to be a claim agent, a superintendent or chief claim agent. The chiefs regard their own individual men as assistants to them, and in that way it is possible to develop men who are better acquainted with the business of claims.

In connection with office kinks, some trouble is often experienced in locating files where there is more than one office. This is overcome by a "cherry card." This must be made out and go to the central file showing the minute the file moves from one person to another, from one room to another. We have used as many as 500 cards a day, and a check for three months has shown only six errors in handling all those cases.

As to fixed principles, we have adopted for our own guidance the following six slogans: maximum accuracy, utmost expediency, absolute fairness, persistent courtesy, minimum consistent expenditures, and perfected co-operation and efficiency. By maximum accuracy we mean incontrovertible facts unearthed from all available sources. Utmost expediency means the promptest action in accord with propriety and correctness. Absolute fairness embraces a fixed, irrevocable policy of dealing with justice to all concerned. Persistent courtesy may be defined as constant politeness combined with kindliness. Minimum consistent expenditures are disbursements proportionate to all the facts, and perfected co-operation and efficiency mean working in harmony to produce the most satisfactory results with the least expenditure of time and effort.

These principles have been in use in our department for five years. In October, 1912, we had a very serious accident in which ninety-six people were injured. We started to give our principles a test on that particular case. One of the first men settled with was paid $50 for two broken ribs. When the adjuster told me how much he had paid, I sent him back with a letter and an additional $50. The man happened to be the president of the board of trade of that particular district, and he was so impressed with what he thought was an unprecedented act of courtesy that he, without any solicitation on our part, used his efforts to help us out in his territory. We built from that case right on up. Every man we went to see we told about the last man with whom we had settled, and we paid from $50 to $15,000. Despite the efforts of attorneys we disposed of every one of those ninety-six cases without a single suit being entered, at a cost of $104,000. They were handled throughout with this idea of fixed principles, which we advertised to everybody.

In addition to constantly and persistently dwelling upon these fixed principles, the chiefs of the different bureaus use the following seven guiding principles:

1. Street railway transportation companies do not insure passengers or pedestrians against injury or damage. It is wholly unreasonable to suppose all persons injured in connection with a street car are entitled to damages.

2. If an accident occurs the principal should not depend solely upon the conductor to make a report but should secure the number of the car or the number of the motorman or conductor, the exact location, and the exact time.

3. If any personal injury or property damage results for which the principal was not to blame and feels justified in making a claim, he should frankly report the details of the occurrence to the claim department, together with the names of the witnesses, and give every possible assistance in making an unprejudiced investigation of all the facts and circumstances. Only dishonest claimants object to a thorough inquiry being made to corroborate the facts.

4. A claim is purely a business proposition, not a matter of law, and should be presented and handled on the same basis as any other allegation of indebtedness. Proving a claim is the same as proving a bill for work done or goods furnished.

5. Any legitimate claimant making a reasonable request for reimbursement can secure a satisfactory disposition of his claim without the expense of assistance. Since a claim is the same as a bill it is bad judgment for a claimant to employ an attorney or enter into the embarrassment, delay and uncertainty of a suit without first presenting his proof of indebtedness direct to those whom he believes owe him.

6. Only three classes of people bring suits for damages against railways, viz: (*a*) prejudiced persons unacquainted with the principles governing the handling of claims; (*b*) persons entitled to something but who want more than they are entitled to; and (*c*) persons entitled to nothing but who want something regardless of their right to it.

7. Citizens who encourage litigation, whether "ambulance chasers," neighborhood gossips, misinformed friends, or someone seeking to profit from another's misfortune, should remember that in so doing they add a burden to every taxpayer, as the expense of the courts is assessed against them.

In addition to the above principles the company uses certain psychological processes in its claim work. The first is to overcome prejudice, the second to inspire confidence, the third to analyze and reduce to a business basis, the fourth to create a desire, the fifth to cause a determination, and the sixth is to close the transaction. By overcoming prejudice we endeavor to show by logical argument that what is true is right. To inspire confidence we mean both to trust and to rely, causing others to believe in us and realize that we are sincere in our desire to deal equitably with everyone. By analyzing and reducing to a business basis we mean to prove by calculation the weight of the facts and pay according to their value. By creating a desire we mean to bring into existence a desire for what will reasonably compensate claimants for their losses, considering the degree of such losses. To cause a determination we bring a man's mind to the opinion that he will exchange his claim for a fair price for the damage done or loss sustained. To close the transaction satisfactorily is to make amends for the injury and then satisfactorily terminate the matter.

One psychological point may well be emphasized. A person will believe anything that may be said to him unless some negative idea comes up in his mind. In order to prohibit a negative idea a positive idea must be injected, and in order to inspire a positive idea a negative idea must be prohibited. For instance, an adjuster says to a woman: "Will you submit to an examination?" or "Will you allow us to have an examination made?" or "Will you undergo an examination?" These questions immediately put a negative idea into her mind on account of the objectionable thought of undergoing or submitting to anything. In our company when an examination has been refused, declined or not granted, we write a letter simply instructing the claimant to arrange through his doctor with our doctor for an examination, without even suggesting the possibility of his being able to refuse such a request. Thus far in the list of cases handled, only one refusal to this plan has been made.

We even go so far as to prepare the claimant before he gets on the department floor. When he comes into the reception room there are many things to attract his attention and divert his mind from his real or fancied injury. There are pictures of President Taft and several local notables at a ball game in Pittsburgh, cartoons of "Mutt and Jeff" making claims, and the old picture of the cow with men at her horns and her tail pulling in opposite directions and an attorney milking—in other words, getting the cream while the claimant and the claim agent are fighting. These pictures have actually been known to turn people back to an offer already made.

The American Association has decided to adopt fixed principles and policies in order to appeal to the public. If the parent association finds this advisable, why would not the Claims Association also find it advisable? There is nothing in the principles enumerated that a company should not desire. Claim agents should assume that the public does know that there is such a thing as a claim department and that claims for damages are paid, and they should appeal to the public and put them on their honor until they do something dishonorable.

DISCUSSION BY MR. TICHENOR

In commenting upon the paper by Mr. Rice, William Tichenor, claim agent Terre Haute, Indianapolis & Eastern Traction Company, Indianapolis, Ind., said that all communities contain many excellent people in all professions and callings, and that if all men, including claimants against railroad companies, were of this character, the public would be entitled to be treated with absolute courtesy, fairness, frankness and firmness, being given full credit for truthfulness and honesty. Unfortunately, however, the portion of the public met by the claim agent and dealt with by the claim department of the present day is not composed of this kind of people. The claim agent comes in contact with only a very small fraction of the public, and a very large part of that fraction seems to be seeking something for nothing without being over-particular as to the source of supply or the method of obtainment. This class is seemingly growing larger and less scrupulous as time moves on.

It appears to be the policy of some companies to treat lawyers and doctors with great courtesy, taking care of their bills, especially the doctor's bills, for the purpose of inducing them in some way to change their methods and give the company a square deal instead of rendering all assistance possible to prosecute "fake" claims. Mr. Tichenor mentioned the case of one company that had a great number of unsettled lawsuits. In this instance the plaintiffs' lawyers were taken into the company's confidence and were treated so courteously in the settlement of the suits that the company now seldom has a suit filed against it and has not lost a suit in three years. If claim agents and claim departments generally could pursue the same policy with the same sort of success, it would be well for such a policy to be widely adopted.

In another case the claim agent of a city and interurban line said it had become such a custom with him to visit the doctor, direct him to take care of the patient until recovery and then present his bill for payment, that it really might be counted as the policy of the company. Both of the above men, the friend of the lawyer and the friend of the doctor, evidently were successful with the policy of dealing with the public in the way suggested, but Mr. Tichenor felt that the experience of claim agents has not been such as to justify the adoption of such customs as a general policy of claim departments.

Mr. Tichenor believed that while a particular claim department may adopt particular policies and principles and adhere to them more or less religiously, general policies on "the relation of claim departments to the public," "the psychology of claim adjustments," "efficiency in claim department work," or "office kinks in claim departments," are wholly impractical, if not impossible. If a general policy were adopted by the association in order to meet the exigencies of any particular case, it would necessarily have to be so modified and reconstructed to meet the peculiar circumstances and conditions of particular cases that it would not be recognized by its author.

DISCUSSION BY MR. HANDLON

J. H. Handlon, claim agent United Railroads of San Francisco, San Francisco, Cal., noted the change in the attitude of the claim departments of street railways to the public within the last few years. Many street railway claim agents early in the field prided themselves to such an extent on their detective ability that they became dominated by their suspicions and grew to consider every person dishonest who had the temerity to file a claim against their employers. They treated the claimants accordingly. Not only was it morally wrong, however, for claim agents to do so, but experience has shown that it was not good business judgment, for unfair settlements are always extensively advertised and to-day jurymen often cite such instances as their excuse for penalizing companies by awarding excessive verdicts.

The successful claim agent realizes that there are honest claimants and that the good-will of the claimant, and particularly of all attorneys and physicians with whom he has business relations, is a personal asset. Moreover, he strives to secure this good-will without any other consideration than fair and courteous treatment.

Certain electric railways are now required to pay unreasonable sums in settlement of personal injury claims owing to the fact that competitive companies are very liberal in their settlements. Other claim agents are unable to reduce their settlements to a fair basis for the reason that their predecessors, in their generosity, educated the public to expect to profit materially from street car injuries. It is very difficult under these circumstances for a conscientious claim agent to instill in the minds of claimants the fact that accidents are regrettable, that the company is adopting every reasonable precaution to prevent them, and that claimants should not seek to profit thereby.

Mr. Handlon said that it is often wise to relieve attorneys of the necessity of visiting the office of the claim agent until the claim is ready for adjustment. This can be done by having a representative gather all available facts from the attorney at his office, or, if he consents, to visit the claimant at his residence. By accommodating the attorney in this respect he is often induced to file the claim rather than litigate a case.

DISCUSSION OF CLAIMS PUBLICITY

BY JOHN J. REYNOLDS, CLAIM ATTORNEY BOSTON (MASS.) ELEVATED RAILWAY

Mr. Reynolds in his written discussion said no substantial ground exists for believing that claim departments have been benefited by publicity of accidents and the sensational illustration of fake, fraudulent, or exaggerated claims, upon which money has been paid or awarded. Claim agents should not allow themselves to be borne away, far beyond the bounds of reason, by a sudden passion to see their fake cases dramatized in story. Such publicity gives specific suggestions with examples of their application and hence serves as a guide to aid the fakir to improve on existing methods and lessen the danger of discovery. That efficiency in claim department work is made more difficult by publicity is unquestionable, and it may well be doubted whether such publicity, beyond imparting to the public the underlying principles that have actuated claim fakirs, has really accomplished the object sought. Most states have publicity laws regarding accidents, under which the public is informed, sufficiently, of all important cases.

Mr. Reynolds at this point introduced numerous newspaper stories to illustrate the reporters' method of "playing up" or "featuring" accidents, with a resulting handicap to the claim department. In his opinion, if newspapers request information concerning accidents, they should be referred to the operating department, and only in the most serious accidents, where persons are injured and removed to hospitals, should the newspapers be given the names and addresses of the injured. Such a course is the proper one for the best results of the claim department, and it is not at all inconsistent with the propagation of that necessary and desirable co-operative relation between the railways and the public.

With regard to magazine publicity claim agents should always be careful to keep in mind the distinction between publicity regarding serious accidents, and publicity concerning the methods of the accident fakir and the methods of the claim department in circumventing him. Take, for instance, said Mr. Reynolds, the magazine publication of the methods by which claim department detectives procured photographs of a farmer plaintiff at work during the haying season. While the evidence procured was of paramount importance to the claim department and perfectly proper to be used either in that department or as evidence in court, such publicity is wholly ineffectual in assisting claim agents to prevent dishonest persons from presenting fraudulent claims. It equips such persons beforehand with an accurate knowledge of what they can do to defeat the most carefully laid plans to trap them. Even admitting the interesting and entertaining character of the numerous fakir stories in magazines, Mr. Reynolds maintains that they are not helpful to claim departments, nor do they help the average citizen to realize that his individual interests, represented by minimum fares and maximum service, are menaced every time the fakir's ill-gotten gains come out of the treasury of the public service company.

To deny such publicity, however, does not mean that these fakirs should not be punished. Mr. Reynolds believes that they should be punished to the limit, but, in so doing, all things should be avoided that may offer suggestions to would-be fakirs. The sort of publicity that will help the claim department is immediate attention to complaints; prompt betterment of service conditions when they can be bettered, and the employment of trainmen who will try to please the public, who will answer inquiries as they should, who will be careful to stop cars when signals are given and who will not jostle people unnecessarily. Publicity of the fact that those essentials are not observed is bound to be felt in the claim department.

It is no exaggeration to say that the claim department of the future will be benefited by publicity. This, said Mr. Reynolds, will be caused not by publicity of accidents and claims, but primarily by the sweeping changes which will have taken place in methods of education in vogue at the present time. That a comprehensive plan of educational publicity is considered necessary to set forth the problems confronting the railways is seen in the parent association's plan for establishing a publicity bureau. A well-organized bureau should be maintained for the purpose of correcting authoritatively and publishing widely all misstatements of fact as fast as they appear. Except in cases of flagrant fraud which are prosecuted in court and which in consequence receive advertisement in that way, the claim department should be kept out of publicity schemes. Expense for publicity should be directed rather toward education along the line of preventive methods.

The accident prevention campaign which is now being seriously conducted by many electric railways is undoubtedly reaching a large portion of the public with excellent results, and claim agents should do every reasonable thing necessary to the end that no longer shall the educational leader hesitate to recognize the widespread demand for a curriculum which will better fit pupils to avoid accidents. Care, however, is to be constantly exercised to keep suggestive matter in the background.

No inexorable rule to be followed blindly under all circumstances should be laid down for claim department publicity. The point to be emphasized is the unwisdom of a pronounced tendency in the matter of claim publicity. What may be justifiable in a given case may be unjustifiable or even pernicious as a general practice. The ultimate adoption of a distinct policy in favor of education is most desirable.

With regard to publicity between claim departments of various roads, there are two general objects to be kept in mind: First, to carry on as widely as possible, with the aid of the index bureaus, a consistent campaign of education through interchange of information relative to claimants reported by the Hooper Holmes or other bureaus. Second, to assist by special work through the local index bureaus in keeping track of claimants that do an interstate business or those whose operations seem to be exceptionally active and extensive. If claim agents at all times keep in touch with this aspect of the business, they will be developing a publicity that will prove a real and permanent benefit to their departments.

NEWSPAPER PUBLICITY DISCUSSED

BY J. S. KUBU, CLAIM AGENT NEW YORK STATE RAILWAYS, UTICA, N. Y.

There is a limit to publicity in connection with claim departments just as to anything else, according to Mr. Kubu's written discussion. The real objection to the general policy of full publicity is the "ambulance chaser," who sometimes creates embarrassing situations. How much embarrassment the claim agent is put to depends a good deal on the efficiency of the department. If the claim agent takes his time and allows the "chaser" to obtain possession of the facts of a case before he himself knows them, the company will find it unprofitable in dollars and cents and will have to bear an additional burden in defending a law suit. Unfortunately, the greatest difficulty is the foreigner who cannot read and does not understand the language, for there are plenty of "ambulance chasers" who speak the foreign languages and have no difficulty in securing clients.

There ought to be a cordial co-operation between the newspapers and the claim department. When an accident occurs which has news value, the claim agent should get in touch with the newspapers and give them definite information that will correct any and all rumors. Very often it will save the city editor the task of assigning a reporter to a job. This line of work in the company should be assigned to one man. News of all accidents and litigation should reach him first and he can then use his discretion in communicating such information to the newspapers. He must, however, know how, and when, to act, and aim at the right kind of publicity rather than at more publicity.

Mr. Kubu remarked that in the matter of litigation the public records are open to inspection and it is a very easy matter to get a copy of a petition or a complaint. When an action at law has just been brought out and is called to the attention of the newspaper man, he will, if he is friendly to the company, get in communication with it and give it a chance to defend itself before publishing the case.

The "safety first" campaigns have been given great publicity by the newspapers throughout the states, and their liberal support has contributed greatly toward the success of such campaigns. This only emphasizes the great interest which newspapers have in the subject and makes clearer the value of the co-operation which should exist between newspapers and railway companies in connection with accident publicity.

Changes In New York Subway Track Practice

At the Oct. 16 meeting of the New York Railroad Club, O. O. Dixon, assistant engineer Interborough Rapid Transit Company, read a paper describing the changes that have been made in the track standards of the subway division since its opening Oct. 27, 1904.

The ballast of ¾-in. trap rock 5 in. deep has been retained, but the 5-in. x 8-in. x 8-ft. ties are renewed with 6-in. x 8-in. x 8-ft. timbers, and on curves the tie spacing has been reduced from 22-in. to 18-in centers.

Originally the inclined guard rail on curves was bolted to the low rail about every 3 ft., using adjustable cast-iron separators to take up the wear. It was soon found that the inclined guard rail was so flexible that it concentrated the pressure on bolts, causing frequent breakages. When the bolts held the wheels were allowed to side slip between the bolts, due to the flexibility of the guard rail, and much corrugation was so caused. This guard rail has been replaced by another of the same section as the running rail, having one flange sheared off, and the adjustable separators were replaced by a one-piece separator to give the correct flangeway. The gage has been widened from 4 ft. 8½ in. to 4 ft. 8¾ in. for curves between 200 ft. and 500 ft. and to 4 ft. 9 in. for curves less than 200 ft. radius.

The first 100 lb. A. S. C. E. rails were manufactured by the bessemer process of the following composition: Carbon, 0.58 to 0.63 per cent; manganese, 1 to 1.10 per cent; phosphorus, 0.09 per cent; sulphur, 0.05 per cent; silicon, 0.07 per cent. However, the specifications were gradually changed to higher carbon rails to get better wear. At present the company specifies carbon 0.75 to 0.90 per cent with an average of not less than 0.90 and manganese 0.60 to 0.90 per cent. Since 1909 the side of the rail head has been sloped to conform more closely to the shape of the wheel. Thus the vertical wear has been slightly increased and the horizontal wear decreased, thereby increasing the life of the rail. A comparison of the life of the rails and tonnage passing over a curve, which has a radius of 220 ft. and a grade of 1.15 per cent down and over which the average speed is 18 m.p.h., shows that in comparing bessemer and open hearth rails the wear is about 1 to 2 in favor of open hearth. The ratio of wear of manganese to bessemer is 1 to 9 and the ratio of wear of manganese to open hearth is 1 to 4½. The soft bessemer rails have proved more liable to corrugation than the harder rails. The manganese rail was satisfactory except that, like all other rails, it was liable to corrugate. Manganese rails are being used on most of the important curves with somewhat varying results, but the company believes that it pays to use manganese if the price is not too high, because less renewals are required.

Switches have been reinforced and the high speed switches lengthened from 16 ft. 6 in. to 24 ft. Where the former bessemer switch point gave a service of three weeks, cast manganese gives about thirty weeks, and in frogs and crossings about five times that of bessemer. Rolled manganese stock rails help greatly to increase the life of the switch points and are in general use.

The ballast in front of stations is renewed about every two years at express stations and every five years at local stations. Few ties have been renewed except at switches and on curves where they have split, due to frequent rail renewals, also where they were decayed due to dry rot. In making the renewals one rail is removed and new ties complete are installed for a rail length.

Screw spikes have not been used much because of the changes they would require and also because of the difficulty they would involve in making rapid renewals of rails.

Railway Electrical Engineers' Convention

Electric Headlights and Electrification Were Among the Subjects Discussed

The seventh annual convention of the Association of Railway Electrical Engineers opened at the Hotel LaSalle, Chicago, with a reception and dance on the evening of Oct. 26. Electrical manufacturers made exhibits in thirty-five booths and in the hotel ballroom. On Tuesday morning the first regular session was opened by President C. R. Gilman, Chicago, Milwaukee & St. Paul Railroad, who reviewed the history of the association and referred with pride to the work accomplished by it since it was formed six years ago. Following his address, Secretary J. A. Andreucetti, Chicago & Northwestern Railway, reported the association in a flourishing condition with a membership exceeding 500.

Reports of the committees on loose-leaf binders for filing specifications on reciprocal relations, and on specifications for wire crossings were brief and indicated progress. The report of the committee on data and information consisted of a tabulation of car-lighting statistics, shop and station equipment and motors for traveling cranes. On the latter topic the committee reported a chaotic condition in the matter of motor sizes, and this will probably be a subject for standardization during the coming year.

On Wednesday morning the report of the committee on standards was received and was followed by the report of the committee on electric headlights. The latter report discussed types of machine, location of generator, voltage adjustment, cab lamps, reflectors, wiring and repair parts. On the question of incandescent headlights, it was stated that while all railroads have been experimenting for some time with Mazda, tungsten and nitrogen lamps for headlights, there was none on the market with a concentrated filament, high candle-power and sufficiently long life to justify its use. The committee, however, was of the opinion that such a lamp would be produced within the next few months, as many manufacturers are now working along that line. It was predicted that when these lamps were a commercial article, the arc lamp would be a relic of the past on engines, as well as for shop and yard lighting. The report also called attention to the battery headlights which are being used with good results on the Southern Pacific Railroad. These lamps are 140-cp nitrogen-filled tungstens and require 13 amp at 6 volts.

At the Wednesday afternoon session the committee on industrial trucks recommended a standard capacity, a standard speed, a standard for tires and wheel sizes and a standard potential of 24 volts for general industrial truck service.

REPORT ON ELECTRIC TRACTION

This was followed by the report of the committee on electric traction, which was a description of existing railroad electrifications. This report was of a preliminary nature and further data, particularly as to operating costs, will be supplied in subsequent reports. Among the topics covered this year was a review of the different electric traction systems, including low-voltage and high-voltage direct current and the three different types of alternating-current systems. Regarding the choice of system, the committee states that it will depend on the extent of electrification, character of traffic and local conditions, but that it will be principally an engineering determination. The report also discusses the reasons for electrification, and the benefits to be derived from the electrification.

Upon the question of electrification of single-track roads the report states that it is a demonstrable fact that more traffic can be handled electrically than by steam on account of the facility of train movement and that it is possible to maintain higher schedule speeds without increasing the maximum speed. It can be shown in the case of a single-track road operating at full capacity, that electrification will enable it to handle additional traffic, thus postponing double tracking. The fixed charges saved on the cost of double tracking for this period may properly be credited to the electrification annual expense in calculating the economics. Other points of interest discussed included the electrification of passenger and freight yards, the sources of power supply, the construction costs and annual expense, locomotive maintenance and the economics of electric traction.

The Wednesday afternoon session closed with a report of the committee on wire specifications which was devoted to improving this association's specifications to make them conform with latest engineering practice.

New National City Bank Publication

The National City Bank of New York has this month begun the publication of a magazine called *The Americas* in the hope of bringing the business men of the United States and South America closer together and providing an instrument for the interchange of ideas regarding the aims and projects of Pan-American commerce. The October issue contains articles on the following subjects: "The Opportunities and Responsibilities of Trade Expansion," by Frank A. Vanderlip, president National City Bank; "A Message from the Argentine Republic," by Enrique Carbo, minister of finance; "The Government Work for Trade Expansion," by William C. Redfield, Secretary of Commerce; "Advantages of Direct Foreign Exchange," by John E. Garden, vice-president National City Bank, and miscellaneous articles regarding the new South American branches of the National City Bank, trade and finanical conditions and requirements in South America and also South American traveling, shipping rates and general statistics.

The National Associations and the Educational Institutions

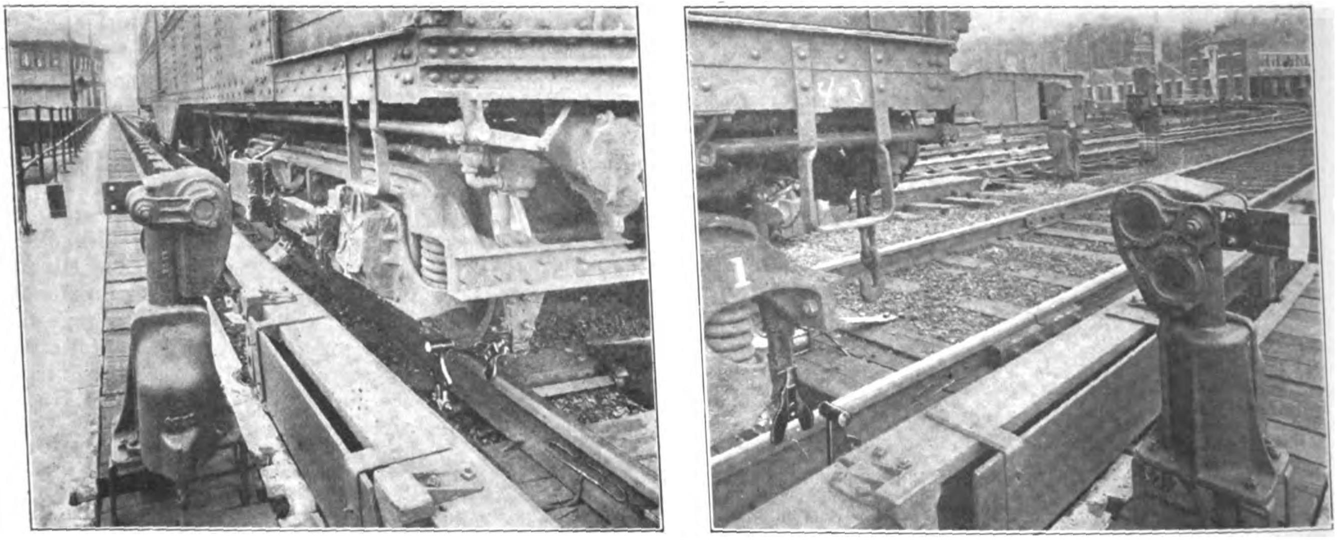
In connection with the suggestion made by the committee on public relations of the American Electric Railway Association that lectures should be given in educational centers by leaders in the industry it is interesting to note that the National Electric Light Association has a committee on relations with educational institutions of which John F. Gilchrist, vice-president Commonwealth Edison Company, Chicago, is chairman. This committee has just announced the plan of its work for the coming year and has appointed four sub-committees on lectures, employment of graduates and undergraduates, courses and curriculums, and supplying information to economic departments, respectively. Each of these sub-committees is under the chairmanship of a prominent educator and the vice-chairmanship of a prominent electric lighting company executive. The membership of the sub-committees is made up of men conspicuously identified with lighting and educational interests.

The Peoria (Ill.) Railway has been appealing to the public and especially to lady passengers to observe carefully the right and the wrong ways of leaving a car. An advertisement is being carried in the Peoria papers showing two women leaving a car, one of whom steps in the direction the car is moving and alights in safety, while the second woman steps in the opposite direction to the motion of the car and falls into the street.

Signal Maintenance on the New York Subway

The Methods and Organization of the Signal Maintenance Department of This High-Speed Rapid Transit Line are Described in Detail and Statistics Covering the Number of Signal Failures on the Line are Given

The automatic block signals on the New York Subway, which is operated by the Interborough Rapid Transit Company, undoubtedly exercise a more potent influence on traffic than those of any other railway system in the world. A practically unlimited number of additional trains could be filled with passengers if they could be operated upon the line, but there is no possibility for the installation of additional tracks. In consequence, an extraordinary premium is placed upon any means whereby traffic can be accelerated, and the subway is now handling actually twice the traffic for which it was originally designed. The large part that signals have played in accomplishing this result may be judged by the fact that the rush-hour train headway has been reduced from 124 seconds to 100 seconds. In addition it should be noted that since the subway was built more than 2,000,000,000 passengers have been carried without a single serious collision between trains.



NEW YORK SUBWAY SIGNALS—VIEW OF DWARF SIGNAL AND AUTOMATIC STOP, SHOWING AIR-BRAKE VALVE ON TRUCK BEFORE AND AFTER RUNNING BY TRACK-TRIP

The signal installation by which this extraordinary result has been accomplished consists of 1233 automatic block signals, of which the majority are of the light-signal type owing to the fact that they are installed in the covered section of the subway tube. In addition there are 561 automatic stops of the mechanical trip type, one of these being placed at every main-line signal mast. All of these signals are controlled by a single-rail-return track-circuit system which was installed in 1903 by the Union Switch & Signal Company. Naturally the organization by which this apparatus is maintained is of unusual importance, especially in view of the fact that on account of the short headway any delay causes a blockade of serious proportions.

In general the signal department is made up of two organizations that report to the signal engineer, J. M. Waldron, one of them having to do only with the construction of new work and the other being responsible for the maintenance and operation of all signals, automatic stops, transformers, motor-generators, storage batteries, air compressors, signal wiring and interlocking plants that are actually installed. The interlocking plants are an important feature in the general scheme of operation, as they are located not only at points where shifting movements normally take place, but also at several points along the line where crossovers are installed to provide for emergencies that require trains to be turned back before reaching a terminal.

All maintenance work is carried on by employees classed as signal maintainers and helpers, the line being divided into a series of sections, on each of which at least one man is stationed during every hour of the day. On each section is provided a cabin for the signal maintainer in charge, and these cabins are generally located at interlocking plants so that the maintainers can operate the interlocking machines in case of blockades. The cabins are usually placed on the station platforms giving the signal maintainers ready opportunity to consult with motormen of passing trains, so that they can be called upon to do emergency repair work upon any part of the subway equipment should occasion demand it.

METHODS OF INSPECTION

The inspections of each section by the signal maintainers to whom it is assigned are not made at any set intervals, owing to the fact that the amount of attention required at different points varies from day to day; but, in general, all apparatus is inspected at least once in every twenty-four hours. Some of the signals are, however, regularly inspected twice daily, and the prevalence of iron dust, the difficulty of pumping sewage and the requirements of track maintenance may even involve practically continuous attention to certain signals or to a certain part of the section for several days at a time. Stuck signal relays, which prevent a signal from clearing after the train which has set it has left the block, are of rare occurrence. However, the rule is in force that, in automatic territory whenever a stop signal is encountered, the train may proceed under control after a wait of one minute. In such cases the automatic stop, which would normally prevent the passage of a train, is held in clear position by the conductor, who is provided with a special key for unlocking the stop, and the train is thus enabled to pass it. After "keying by" a stop signal, if the next signal is found to show that the track ahead is clear, it is obvious that the signal passed has displayed an improper indication. In such cases the motorman gives a whistle signal when he comes into the next station where there is a signal maintainer. The signal maintainer upon receipt of the whistle signal goes back along the track until he finds the signal that is in bad order.

As an example of the results that can be obtained by the continual application of this close attention to the maintenance of the signals a statement of signal failures on the subway is reproduced in Table 1.

TABLE I—SIGNAL FAILURE RECORD ON NEW YORK SUBWAY

	1911-1912	1912-1913
Number of signals	1,212	1,233
Number of stops	552	561
Total	1,764	1,794
Total number of signal failures	273	173
Total number of stop failures	240	163
Total mechanism failures	513	336
Total number of signal movements	109,504,253	124,333,070
Total number of stop movements	66,683,176	70,800,273
Number of signal movements per signal failure	401,115	718,688
Number of stop movements per stop failure	277,846	434,357
Number of failures per signal per year	0.225	0.140
Number of failures per stop per year	0.435	0.291
Number of failures per mechanism per year	0.284	0.186

By this is shown that a large decrease in the number of failures of signal apparatus characterized the year 1912-1913, the fiscal year of the Interborough Rapid Transit beginning July 1 and ending June 30 of the following year. This large decrease was principally due to the work of fire protection which had been done on the signal system during the year 1911-1912. The record of over 700,000 signal movements per signal failure undoubtedly establishes a high record even for lines where intensive traffic is carried on. In the table the term "signal failure" is used in its broadest sense and is understood to mean any stoppage of a train for reasons other than that of a train in the block beyond. Cases of outside interference, such as where a bundle of newspapers is dropped from a passing train upon a track trip, and where motormen improperly report a signal out of order are, of course, not included.

NEW YORK SUBWAY SIGNALS—TRAIN STOPPED BY MAIN-LINE SIGNAL, TRACK-TRIP AT STOP IN FOREGROUND

NEW YORK SUBWAY SIGNALS—INTERIOR OF TYPICAL INTERLOCKING TOWER

An analysis of the signal failures occurring during the year 1912-1913 is also published in Table II. This divides the failures into various classes of defects and shows the number of each kind of failure that occurred during each of the twelve calendar months. It will be seen that only two of the signal failures occurring during the year were due to unknown causes. The five cases of signal failures charged to "broken or defective grid resistances" were due to defects in the resistance which is installed in series with the track relays in order to prevent the return propulsion current from passing through the relay and thus burning it out. This is necessitated by the fact that the installation is of the single insulated rail type in which the operation of the signals and the compressed-air valves for the switches and interlockers is effected by d.c. relays, the alternating current being used only for controlling the track relays and for the signal lights. The solenoid signals referred to in the table are of a home-made type in which the usual slot coil is replaced by a solenoid that operates the semaphore blade directly.

ARRANGEMENT OF MAINTENANCE FORCE

As mentioned before, each section is inspected complete every day, but as the main-line sections are ap-

TABLE II—CLASSIFICATION OF SIGNAL FAILURES FOR 1912-13, NEW YORK SUBWAY

Cause of Failure	July	August	September	October	November	December	January	February	March	April	May	June	Total
Scale on insulating joint	3	4	2	4	..	..	4	2	2	3	2	6	32

Defective or burnt out transformer	1	..	1	..	..	1	1	1	1	2	..	..	8
Total	17	20	9	17	16	14	16	16	14	14	13	7	173

proximately 1½ miles in length the difficulties of transportation are negligible. The section length of 1½ miles is maintained quite closely except in the case of certain complicated places, such as the terminals and at the points of diverging routes like the Ninety-sixth Street junction. The number of signals in each section varies approximately between forty and eighty with about half as many automatic stops, and under normal conditions three signal maintainers keep in repair all of the apparatus on each section. These three signal men, however, work in three ten-hour shifts, the attention to signals, therefore, being continuous. The ten-hour shifts are so arranged that the overlap comes during the early morning hours, because all of the heavy work is done between 1 a. m. and 7 a. m., this being the only period when the traffic is relatively light, the train headway on the local tracks being increased to 7½ minutes during this period.

At the points where interlocking plants are kept normally in continuous operation and where there are air compressors, storage batteries and transformers, each signal maintainer is provided with a helper, and it is from this force of helpers that the signal maintainers are developed. Owing to the fact that the main-line sections are of an approximately constant length and are arranged almost regardless of the number of signals, certain of the sections are considerably easier to maintain than others. On the easy sections the less experienced men are placed and they are advanced to the more difficult positions as their experience becomes extended. Ordinarily, the helpers serve in that position for about two years, after which time they are generally capable of maintaining some of the easier sections. In general, the force of helpers is recruited from construction gangs, as a certain amount of construction work is being carried on all the time.

The signal maintainers do no actual repair work to damaged parts of signal apparatus, the replacement method of field work being carried out in all cases and the maintainer being required only to make the necessary replacements and adjustments. Practically all repairs to damaged apparatus are made at a central repair shop that is located at one end of the line. Here three repair men are employed continually in rewinding coils and in doing other heavy repair work on apparatus that has been sent to the shop. In addition an extra signal maintainer is kept at work in the repair shop during normal conditions so that in case of the failure of any one of the regular signal maintainers to report for duty the spare man can be called upon to take the temporary vacancy. Practically no repair work has to be sent to the signal manufacturers, and, as shown by the number of repair shop men employed in proportion to the number of signals and automatic stops that are maintained, the repair work is normally very light.

No lightning damage has been experienced even in the case of the outlying sections of the subway that run upon an elevated structure. This unusual condition is ascribed to the fact that an iron fence is run along the entire length of the elevated structure and is grounded to the steel framing.

A plan has been formed to construct new carshops in south Russia, and negotiations are going on for the organization of a stock company. The originator of the plan is said to be a well-known banker and manufacturer. It has been reported that the manager of the Compagnie Centrale de Construction Haine-St. Pierre, the largest car and locomotive works in Belgium, has gone to south Russia to determine the location of the proposed works.

COMMUNICATIONS

Operation Without Train Orders

THE SOUTHWESTERN ELECTRICAL & GAS ASSOCIATION
DALLAS, TEX., Oct. 10, 1914.

To the Editors:

Referring to the article in the Oct. 3 issue of the ELECTRIC RAILWAY JOURNAL entitled "A New Method of Traffic Acceleration" and to your editorial on the same subject, the writer operated one of the early interurbans twenty years ago and introduced somewhat the same plan as that used by the Scranton & Binghamton railroad. On this line the question of operating under signals or under train orders was discussed, and while the signals of that time were rather crude, cumbersome and somewhat unreliable, they seemed, in conjunction with the time-card and a delay-time-limit, strictly enforced, to be able to eliminate a great deal of waste time, and would also tend to increase vigilance and accuracy on the part of the trainmen.

The interurban road was about 15 miles long, and very often it ran trains of two cars, having at times heavy rush traffic. It was divided into six signal sections, approximately equal in length, but some allowance was made on certain sections for the delaying action of curves and grades and the sections were really divided more by a question of time than by exact distance. The trainmen were made to equip themselves with standard watches, which were inspected weekly and compared with a standard clock at the starting point at the office on every trip, and they were thoroughly trained in the observance of the delay-time-limit principle.

The practice was that a car, on time at a regular passing point, waited for a scheduled meet for the length of time that it would take the opposing car to run from the turnout in advance. It then started on its way with caution, that is to say, at danger points, such as curves or where the meeting car could not be seen at a fair distance, the car was brought under control for immediate stop. Signals were accepted at their face value and the signal system was so arranged that any failure on its part to act resulted in a caution indication. No stop signal was instituted, the signals showed either that the block was certainly clear in front or that it supposedly was not. In the former case the signal governed, in the latter case the delay-time-limit governed.

Where a car broke down between turnouts, say centrally between them, there was a certain amount of delay, but as each car on both sides of that broken-down car followed the same rules, the final result was that they soon came up on each side of it, transferred their passengers around it and from it and returned on the schedule time of the next, or succeeding car.

Every car or train going over the road had its train number and each motorman was daily furnished with a group of printed cards giving the scheduled time of arrival and departure, at termini and at each turnout, of every car or train on the schedule for the day, and in case of a break-down certain of the interurban cars would temporarily lose their train place so far as the schedule was concerned. Every car had on the front of it, on the left side, a plate carrying its train number for the day, the plate being illuminated at night. On regular schedule, with no accidents or delays, every motorman knew the number of the train that should meet him at each turnout, and the instructions to motormen were that, when they met with a car or train carrying some other train number than that which should be at the turnout under normal schedule, immediate inquiry should be made and information given by the other car crew as to the reason for this. This tended to make the man who was on schedule time more careful, as he was then informed that the regular schedule was broken and that extra caution was necessary and, also, that extra exertion was desired so that the regular schedule might be again resumed as quickly as possible.

These orders and operations, in conjunction with the block signals, allowed the road to be operated at what was, at that time, a very high speed, that is to say, with some six or eight stops the cars averaged over 30 m.p.h. with some heavy grades and some curves of small radius. During one year's operation of this road, with very heavy traffic, there was only one collision, and that was caused by absolute wilful disregard of the rules.

It is surprising even on a road of considerable length and many passing points, how soon the trainmen become habituated to the system if proper supervision is given and the watches strictly checked. There is also an astonishing amount of time saved by this system over that of train orders, especially on rush days. The writer has, since that time, operated roads under the dispatcher system simply because that system had been installed from the beginning, everyone was used to it and it seemed unwise or undesirable to change it. But in starting to operate a new road of this character it should most decidedly be operated entirely by block signals and proper delay and cautionary rules. With the same check and supervision given to each one, the chances of accident are greater with the dispatcher system than with the other, and there is very much less delay and a better opportunity to straighten out the schedule when it becomes temporarily disorganized.

It may be that, under the best arrangement of the block system, more turnouts will be necessary than with the dispatcher system, but this is a matter in which the original cost and maintenance may be definitely fixed and known, whereas the added risk and the delay consequent upon the dispatcher system is an unknown quantity. There may, also, be interurban lines so situated that they are compelled to depend upon individual dispatching, but in a trip made a few years ago over most of the high-speed electric interurban roads in the country, with this particular point in view among others, the conclusion of the writer was that there was not one of all the roads visited in which schedule and safety could not be bettered by abolishing the dispatcher, as a dispatcher, and leaving him merely as a "trouble man" who could be communicated with at every turnout but who, except under extraordinary conditions —provided for in the rules—would not interfere with the movements of the cars, or with the schedule for the day.

It should be said that only a very few rules are needed to cover such a system for the reason that these rules need only govern the contingencies. Once the men are trained into the principle of the system, ordinary operation goes on like clockwork and the new men absorb the idea, by practice, in a very short time. It is being more and more appreciated that the human element is a vital factor in producing both safety of operation and perfection of schedule, and that the nearer the trainmen approach the condition of automatons or dummies the less the good results, as a whole. While, under the signal and delay-time-limit system there are rigid rules that are concerned mostly with absolute safety of operation, yet the matter of maintenance and resumption of schedule after delay or accident is largely in the hands of the trainmen.

The writer has not given this matter much attention the last few years and really was not aware that so little had been done in the line which the Scranton & Binghamton has taken up. He is not very well acquainted with the latest modern systems of block signaling, but from what he has read and observed it should certainly be much more easy and more safe to operate at this time with the improved and more reliable signal systems, than it was twenty years ago with the rather crude and imperfect systems that were then in use.

H. S. COOPER.

ILLINOIS TRACTION SYSTEM

SPRINGFIELD, ILL., Oct. 10, 1914.

To the Editors:

We have read your description of train operation on the Scranton & Binghamton Railroad and your editorial commenting on it in the issue of Oct. 3. This is particularly of interest because we have 175 miles of interurban equipped with track-circuit-controlled automatic block signals of the semaphore type.

We note that movements of trains on the Scranton & Binghamton road are governed entirely by signal indications, and that trains are operated regardless of time-card meeting points and are not under the jurisdiction or handling of a train dispatcher. You have evidently given but a small part of the requirements or duties of the train crews or the method of operation. What happens when a signal or signals are not in operative condition? It appears to me that, in the absence of a train dispatcher, this would create a situation of too much importance to be covered by operating rules or left to the judgment of the trainmen. We note that sidings average 1 mile apart, which requires an approximate running time of three minutes from one to the other, and that there cannot be delay of more than three minutes to any train.

We admire block signals not only for the increased safety they afford but, in addition to this, for the increased confidence which they give to the trainmen, especially in bad weather. In consequence, we think that you are unduly severe when you state that block signals hinder rather than accelerate interurban high-speed traffic and that they comprise merely a safeguard superimposed upon the structure of operating rules. We operate hourly service through signaled territory and we are very frank in saying that the installation of the signals did not in any way hinder operation. On the contrary, we feel that operation has been helped and that it is easier to keep our trains on time since the installation of the signals. In connection with this, however, it should be said that the performance of our block signal is practically perfect, showing a percentage of 99.97 perfect operation. We note your query whether high-speed interurban roads can take full advantage of signal equipment unless they accept signal indications at their face value and run on signals rather than orders, but we are not able to see how the high-speed interurban lines of the north central states, which are now equipped with signals, could operate in the manner which you suggest. The procedure involved in changing the method of operation to provide for the acceptance of signal indications at their face value so that trains can proceed in accordance with signal indications regardless of time-card meeting points is a situation confronted by many physical obstacles on our property and also, I think, on every other high-speed interurban line in the Central States.

Some of the things which I believe absolutely necessary of attainment before this method of operation could ever be considered for our lines include the following: The continuous track circuit would have to be extended from one end of the road to the other, exceptionally thorough inspection of the signal system would be necessary, siding locations would have to be adjusted, time-card would have to be laid out for the new scheme of operation, and trainmen would have to be educated and trained with that end in view.

Not being familiar with all of the existing operating rules of the Scranton & Binghamton Railroad we do not feel capable of making a statement as to the success or failure of the operation of that road on signals alone, yet we do feel that, after all of the things that have above been enumerated have been done, we would not want to undertake the operation of our road through its signaled territory depending on the signals alone to govern the movement of trains. We believe that we would prefer to give the train movements close supervision, provide the best of inspection for equipment, and control the movement of the trains by train dispatcher rather than to undertake and be responsible for operations depending wholly upon block signals. We are basing our opinion in this regard upon the fact that automatic signals have been known to give clear indications when they should give stop indications, and, with service as frequent as every fifteen minutes and trains operating under block signal control, you can readily see what a false clear indication would mean. You can also see what a bad order signal would mean without telephone communication or control of movement by train dispatcher.

Please understand we are not criticising the operation of the Scranton & Binghamton Railroad as a railroad. We are taking exception only to your statement that high-speed interurban roads should take advantage of signal equipment by running their trains under signal control alone, and in doing this we are giving our opinions so that more may be brought out about the real operation of this road which is depending entirely upon its signals for train movements.

C. F. HANDSHY, Assistant General Manager.

Insert Special Work Failures

UNION TRACTION COMPANY OF INDIANA
ANDERSON, IND., Oct. 16, 1914.

To the Editors:

In reading the various articles that have appeared in the ELECTRIC RAILWAY JOURNAL on the subject of insert special work it has seemed to me that what I might write would be simply a repetition to a considerable extent of what has already been written, and a good many of the points discussed are what engineers, or at least some of them, have known for some time. On the other hand, to further this work, I want to add these remarks:

Concerning insert special work, I believe that the construction giving the longest life is that having the machined bed as a bearing. I find that spelter eventually will come out, although I have some frogs that have been in service for seven or eight years where the spelter has come out around the sides but the insert is not yet loose. Of course at these points the traffic has not been as heavy nor the wheelage as great as it has at some other points. The completely machined-fit, bolted-down type appears to be giving the best service and the longest life.

It is folly to expect that any kind of an insert will last forever. The raising of flangeways, for instance, I do not think is going to increase indefinitely the life of a frog or a mate, but I think it is a step toward lengthening the life. All of the photographs that have appeared in the articles showing the floors of frogs and mates cut down by flangewear, are simply the result of natural wear, since these flanges riding on the throatway floors will evidently wear out the material, no matter what it is. On the other hand, I believe we are getting better manganese from the manufacturers now than we did a few years ago. They have learned about the manufacture of this material as well as the engineers have about the use of it.

The cause of inserts becoming loose, I believe, is nothing more nor less than the rolling of the wheels over these inserts. Inasmuch as they are not a part of the casting, the vibration and the impact, due to the wheels, gradually loosens the insert from the material which is holding it in place. The nearer you can bind the insert to the casting itself, or approach making the insert a part of the casting by providing machined bearings and bolts which transmit the stress through the bearings, the better will this insert resist impact and remain firm. Whether or not a solid manganese piece is warranted, I believe depends upon the special conditions of traffic in any given city. I do not believe that with us the expenditure is warranted, but in other cities with more frequent service and greater wheelage, it might be found to be economical to use solid manganese frogs and mates.

With reference to the loose arms in cast-iron bound work, some manufacturers, I believe, make the rail arm in the casting too short. On the other hand, if the joint at the end of the arm hasn't the proper support, it is liable to break. I have never had a frog arm break outside of the casting, but I have had a good many of them come loose in the casting. This leads me to believe that the bond between the rail and the casting is not what it should be. Moreover, we cannot always get first-class joints at the end of the arm in special work, any more than we can at other places, so that a certain factor of safety must be added to the grip area to improve the bond for these contingencies.

L. A. MITCHELL, Superintendent of Roadway.

Effect of Car Wheel Diameter on Motors

LEWISTON, AUGUSTA & WATERVILLE STREET RAILWAY
LEWISTON, MAINE, Oct. 9, 1914.

To the Editors:

I have read with interest the article by H. J. Parks in the ELECTRIC RAILWAY JOURNAL of Oct. 3, 1914, on the "Effect of Car Wheel Diameter on Motors," but do not fully agree with him regarding this effect. As the speed of a railway motor is governed by the load it is carrying, I do not believe that the difference of 1/4 in. in the diameter of the wheels on a two or four-motor equipment will make any material difference in the load on the motors. I have made numerous tests in the past few years and have failed to find any difference in the temperature of the motors operating on axles with different size wheels.

With cars on which cast-iron wheels are used, it frequently becomes necessary to change a pair of wheels which are not entirely worn out; and if new wheels are installed the difference in diameter is sure to be 1/2 in. or more. In these cases I have made tests with the results stated. I have had under my observation cars operating with steel wheels with 33-in. diameter when new. It became necessary to change one pair of these wheels on account of flange wear when the diameter was reduced to 32 1/4 in. A new pair of wheels was installed, but careful tests failed to show any noticeable difference in the temperature of the motors. I have also had installed under the same conditions turned wheels which were 1 1/8 in. smaller than the other three pair, and I still failed to find any difference in the temperature of motors. I do not, however, recommend operating wheels with such a difference in diameter.

When making these tests the motors on several cars operating under the same conditions should be tested in order to make a fair comparison, as many complications might arise to cause the overheating of a particular motor or set of motors. I should like very much to hear from other experienced men on this subject, as I believe it is a benefit to exchange ideas.

C. H. NOTTAGE, Master Mechanic.

OHIO ELECTRIC RAILWAY
COLUMBUS, OHIO, Oct. 10, 1914.

To the Editors:

I feel that I must challenge the statement of brother Parks from East St. Louis in your Oct. 3 issue, page 623, where he writes that a difference of ¼ in. in the diameter of his car wheels caused two armatures to burn out.

I do not question the sincerity of Mr. Parks nor the accuracy of his statement of fact, but I cannot agree with his conclusions. It is possible that this is a typographical error and that 1¼ in. was meant, in which case I would be inclined to think Mr. Parks had some grounds for his belief that this was the cause of the burn-outs.

This question of the effect of different diameters of wheels on motor load has been one of great interest to me for some years, and I have been hoping for some time that someone would come forward with a demonstration. That a difference in the diameter of the wheels on the same car will cause unequal loading of the motors is an accepted fact, but just how much this is I have never been able to find out. I have even appealed to the experts of one of the best-known companies making railway motors and equipment for a solution of this problem, but received only an evasive answer.

On the property that I represent it is a rule to keep the diameter of wheels on any car within 1 in. of each other, but cases have been known where we have found wheels differing as much as 2 in. In one particular case a careful test of temperature rise was made on motors on a car with wheels differing by more than 2 in. While a difference of temperature rise was shown, the expert making the test could not say how much of this was due to the difference in diameter and how much to other causes, such as different ventilation, etc.

Mr. Parks does not give the diameter of the wheels used, so that it is impossible to compute the percentage of difference, but assuming that his wheels were only 30 in. in diameter, which is about the limit for city cars, we would get for ¼ in. a difference of 0.8 per cent in diameter, which I cannot by any stretch of imagination conceive as the cause of the armature burn-outs.

There is one fact that possibly may not be well known in this connection, namely, that on interurban cars, or cars that run at fair speed, the rear motor of a four-motor equipment will always show the greatest temperature rise. For this reason, if it is necessary to use wheels of different diameters, the longer wheels should be placed in the front end of car and the small ones at the rear so that the motor doing the most work will have the best ventilation.

This subject is of great interest to me and I believe that a practical solution would be of great value, since if we know about what the effect of different diameters is we will be in position to decide how much expense will be justified in keeping the diameters of wheels within certain limits.

This communication has not been written in a spirit of criticism, but rather in the hope that it will bring out discussion and further facts.

F. J. FOOTE, Master Mechanic.

ASSOCIATION NEWS

PUBLIC SERVICE COMPANY SECTION MEETING

At the meeting of the Public Service Company Section of the association, held in Newark, N. J., on Oct. 29, papers were delivered by W. J. Clark, manager heavy traction department General Electric Company, and Martin Schreiber, engineer maintenance of way Public Service Railway. Mr. Clark spoke on "European Public Utility Conditions" and gave a wealth of data showing the comparative results of public and private operation and ownership of utilities in Europe and the United States. His paper was illustrated with numerous charts projected on the screen. Mr. Schreiber described in considerable detail, with the aid of lantern slides, the plans of the Newark terminal, now under construction. He traced the development of the enterprise from its inception less than two years ago and concluded by showing interesting progress pictures of construction. He stated that at the present time a considerable proportion of the caissons for the column footings have been sunk. The operation of sinking the caissons was explained with the aid of a diagram prepared especially for the purpose and adding materially to the value of the paper.

After the addresses the annual election of officers of the section was held and the following were unanimously elected: President, P. F. Maguire, chief clerk maintenance of way department; vice-president, W. R. Ricker, shop foreman mechanical department; secretary, A. T. Warner, traffic investigator transportation department; treasurer, D. H. Roszel, division engineer engineering department; director (one-year term), Thomas Leahey, general foreman distribution department; director (two-year term), George L. Walsh, claim agent Passaic division.

DENVER TRAMWAY COMPANY SECTION NOTES

The Denver Tramway Company Section is now entering upon its third year of work, having been organized Sept. 19, 1912, with a charter membership of forty-eight. The meetings are held in a fine auditorium with a seating capacity of 500, provided by the company at the company's building in Denver.

The opening meeting of the current year was mentioned in the issue of the ELECTRIC RAILWAY JOURNAL for Oct. 10. At this meeting, which was devoted to safety matters, the value of section work was illustrated most effectively. The section first heard an account of the safety work of the Union Pacific Railroad. It was learned that during the preceding two years 3000 recommendations were received by the safety bureau of that company from employees, and 90 per cent of these recommendations were acted upon favorably. The discussion of local problems under the lead of Vice-President John A. Beeler brought out clearly how strenuously the Tramway Company is endeavoring to reduce the number of accidents. An effort was made to connect the accident efficiency of the men with their coasting records, recording fare-register records, etc., but it was found that valuable as these and other mechanical devices are the personal element remains the controlling factor. Mr. Beeler said that the Denver Tramway was the first company in the United States to adopt the center-entrance car and was one of the first to adopt the automotoneer, the straight air brake with emergency feature and other devices. He pointed out a record on one line of 54,000 car-miles per accident, including those of the most trivial character, and stated that a record of 100,000 car-miles would soon be reached. He also showed how proper training with the coasting recorder can produce remarkable results. H. G. Munkhenk is the secretary of the section.

Equipment and Its Maintenance

Short Descriptions of Labor, Mechanical and Electrical Practices in Every Department of Electric Railroading

(Contributions from the Men in the Field Are Solicited and Will be Paid for at Special Rates.)

Types and Cost of Guard Rails

BY CARL H. FULLER, FORMERLY ENGINEER MAINTENANCE OF WAY MACON (GA.) RAILWAY & LIGHT COMPANY

The assertion is frequently made that it is cheaper to buy the raw material and work it up with company forces than to buy the finished product from the specialist. Hence the trackman is often compelled to economize in directions against which his instinct protests, but if he lacks the data to back up his better judgment, he is compelled to yield to the demands for "economy" from the man higher up.

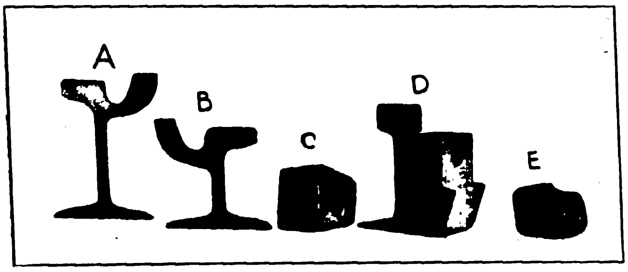

FIG. 1—RAIL SECTIONS AND BLOCKS FOR GUARD RAILS

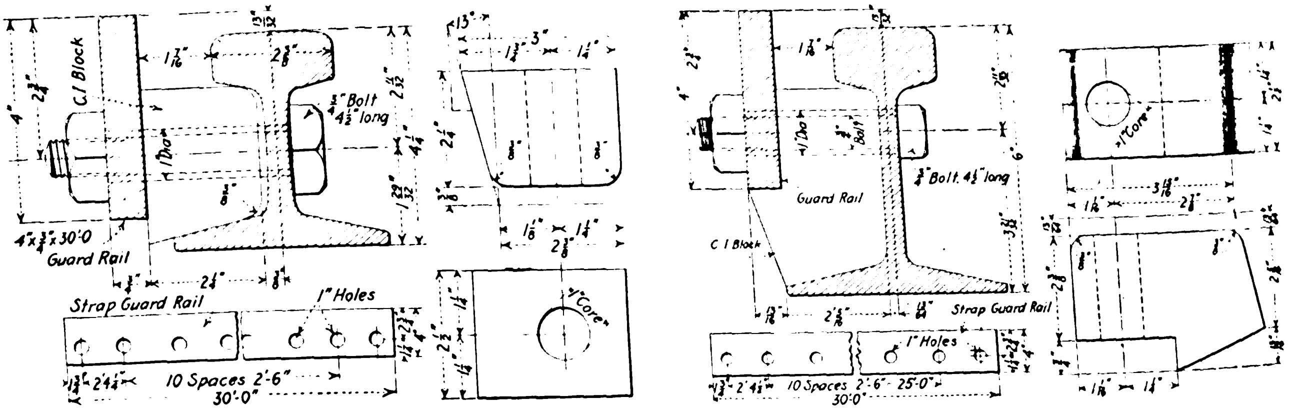
This point is one that comes up in such a matter as guard rails on curves. The writer has always believed that it was impossible to obtain the same satisfactory service and economy from the home-rolled curve. guarded with makeshift devices, as from the machine-rolled rail with the guard attached or made an integral part of the rail. (See *A* and *B* of Fig. 1.) During the past two years he has had an opportunity, not of his own selection, to make a comparison between the cost and mechanical qualities of the shop-rolled curve with guard attached and of the home-rolled kinds. The results of these observations are presented herewith. For the sake of comparison all data will be confined to the use of the standard 60-lb. A. S. C. E. rail section. All labor was paid $1.35 or $1.50 a day and $2.50 for the foreman. All drilling except that done in the shop was carried out with a Duntley electric track drill.



FIGS. 2, 3, 4 AND 5—APPLICATION AND DETAIL OF GUARD RAIL AND BLOCKS

In casting around for a substitute for the shop-rolled curve the writer found that the company had been using old rail or new bar iron bolted to the running rail. The old rail proved unsatisfactory in dirt roads because the working of dirt under its flanges caused the rail to rise until the wheel flanges severed the bolts, and no amount of spiking would hold it down. Further, the strap guard used was of various sizes and drillings, occasionally more than one size being used on the same curve and seldom more than 16 ft. long. In an effort to standardize the use of this material, details were drawn up for a 4-in. x ¾-in. bar-iron guard attached by cast-iron blocks and bolts to the 60-lb. and 72-lb. rail. (See Figs. 2, 3, 4, 5 for details and *C* and *D* of Fig. 1 for views of the finished blocks.) Patterns were made and the blocks cast in quantities at the local foundry for $0.12 and $0.155 respectively.

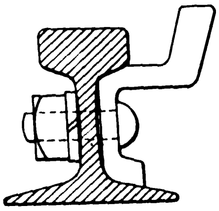


FIG. 6—MILL GUARD

The next step was to buy 2000 ft. of bar iron. The mill quoted $0.174 per ft. with $0.03 added for drilling. We ordered the plain bars and found that we could unload from the cars and carry to the shop, drill on power drill press and put in stores for $0.0291 per ft., or $0.0022 per lb., or $0.0515 per 13/16-in. hole. A second and a third order of the same material was handled for a shade less.

The bending of rails for curves was done on the job with an ordinary trackman's roller and a crew of five men and foreman. Accurate figures cannot be given for this work, but stop-watch observations indicate that owing to conditions it cost an average of $0.077 per ft. and upward.

The following figures for four jobs include the handling of the bars from the storeroom to the job, the drilling of the holes in the running rail with the track drill and the application of the bars, blocks and bolts.

Job 1,	268 ft., at	$0.0286 per ft.
Job 2,	236 ft., at	0.054 per ft.
Job 3,	1560 ft., at	0.0392 per ft.
Job 4,	400 ft., at	0.041 per ft.
Average total		$0.034 per ft.

Assembling our figures we find the inner rail of the curve cost as follows:

60-lb. rail	$0.300	per ft.
Labor bending rail	0.077	per ft.
4-in. x ¾-in. strap iron	0.193	per ft.
Drilling and applying	0.034	per ft.
Cast-iron blocks, bolts, etc.	0.095	per ft.
Total	$0.699	per ft.

Where the track is on private right-of-way where we did not have to contend with the working of dirt under the flange of the rail we used old 40-lb. rail for guard, having a scrap value of $10 per ton, which cost in place as follows:

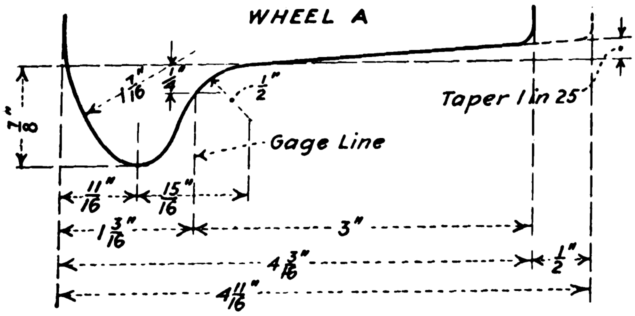

FIG. 7—CONTOUR OF STANDARD A. E. R. A. WHEEL FLANGE

60-lb. rail	$0.300	per ft.
40-lb. rail at $10 per ton	0.065	per ft.
Bending 60-lb. rail	0.077	per ft.
Drilling and applying guard	0.074	per ft.
Cast-iron blocks, bolts, etc.	0.106	per ft.
Total for inner rail	$0.622	per ft.

Recently there was an opportunity to install several curves in solid concrete paving where in order to get smoother riding curves, the mill guard shown in Fig. 6 was used at the following average cost:

60-lb. rail	$0.300	per ft.
Bending rail	0.077	per ft.
Mill guard, Fig. 6	0.533	per ft.
Labor applying guard	0.055	per ft.
Total	$0.965	per ft.

The guard rail section, *B* of Fig. 1, can be bought curved at the mill to a given radius with easements on each end of the curve and delivered on the job for $0.655 per lin. ft.

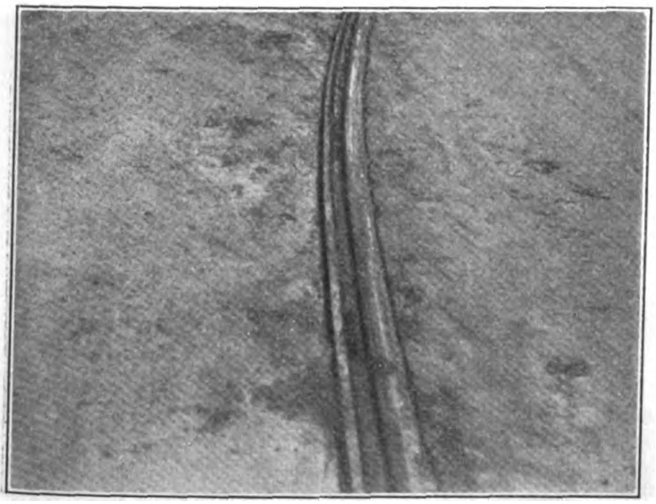

FIG. 8—EARLY STAGES OF WAVE ACTION IN STRAP-GUARD RAIL CONSTRUCTION

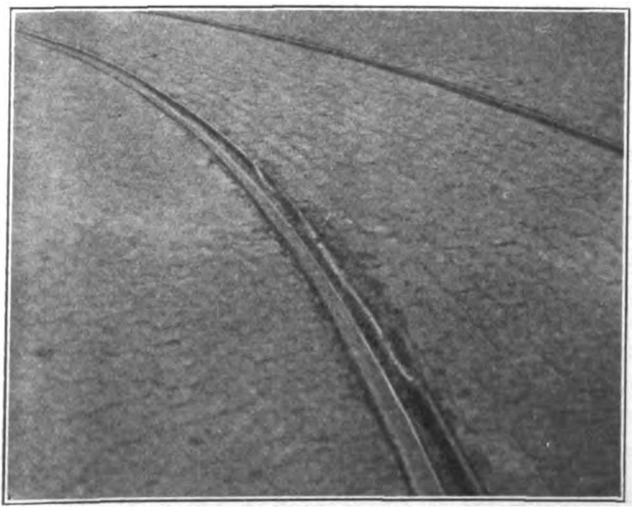

FIG. 9—ADVANCED STAGE OF TROUBLE WITH STRAP-GUARD RAIL CONSTRUCTION

Anyone who will study the contour of the standard A. E. R. A. wheel flange (Fig. 7) a few moments must admit that this rail section is better suited, mechanically, than the guards we have been considering for use on curves. Therefore, we will consider this section as 100 per cent efficient and make comparison of the cost of curves on this basis:

A—Solid guard rail section	$0.655	or	100	per cent
B—4-in. x ¾-in. strap guard	0.699	or	107	per cent
C—Rail guard	0.622	or	95	per cent
D—Mill guard	0.965	or	147	per cent

There is no doubt that the mill guard Fig. 6, is nearly though not quite as good as the solid rail section, *B* of Fig. 1, but it is attached with bolts. The home-rolled curve is bound to be inferior to the shop-rolled curve, and even ignoring the labor to apply it costs more than the solid guard. Consequently, the home-rolled curve cannot be recommended even on the basis of first cost. From the standpoint of cost the strap guard, Fig. 2, and the rail guard, both of which are makeshifts whose only reason for existence is economy of first cost, approach so close to the cost of the mill-rolled curve of solid guard rail that any advantage of initial economy might as well be dismissed.

But when we consider the matter of ultimate maintenance the solid guard with its solid lip is there to stay until it wears out. The mill guard is of good shape and gives an easy riding curve which requires little attention, but bolts will break occasionally where the service is rough on the track. When they do it is sometimes necessary to break out and replace every bolt in the piece owing to the invasion of dirt under it—an expensive and troublesome operation.

A rail section can be used to make a good stiff guard, but owing to its climbing proclivities the rail is unsuitable for use in dirt roads where it is covered up; nor is it suitable for very sharp curves where the bolts break with such annoying frequency that their entire renewal may be required every six months. With a scrap value of $10 per ton there is no economy in trying to use old rails for guards, and even with a still lower scrap value it is questionable if it is not cheaper in the long run to sell the rail and buy the mill-rolled solid guard-rail section.

As for the strap guard, this has proved the veriest makeshift without the argument of first cost to commend it. It will remain smooth for any length of time only on long flat curves. The sharper the curve the quicker does the strap guard develop wavy places, bulging outward under the action of the wheel between the bolts, owing to its lack of stiffness, until the nosing of the cars becomes an inherent feature of the curve. Fig. 8 shows a case where this wave action is beginning to develop. The mismatching of the joint is also noticeable—a trouble that is quickly accelerated by the breaking of a bolt and the possible derailment of a car. In the picture, which shows a curve in a street paved with solid concrete, we see the effect of vibration due to the rough riding of a guard which failed to wear smooth under the cutting action of the wheel. The pounding pulverized the adjacent concrete until the rail lay loose as in a slot.

In Fig. 9 we see the result of wear on the strap guard. First the guard is cut out until it approximates the shape of the mill guard and then it breaks through because of insufficient metal. The views of Figs. 8 and 9 were taken less than two years after this track was laid and on a section where car travel seldom exceeded eight cars an hour. An increase in the thickness of the strap to 7/8 in. or 1 in. only increases the life slightly at an appreciable increase in cost.

In addition the strap and rail guards require more attention from the track greaser than the solid and mill guards, while fully 100 per cent more grease is required, with most of it wasted. If curves of this type are numerous the expense of lubrication may easily become quite an item.

Commutator Slotter with Rotary Suction Fan

BY E. J. HAINES, ACTING ASSISTANT SUPERINTENDENT OF EQUIPMENT BAY STATE STREET RAILWAY, BOSTON, MASS.

The slotting of commutators on railway motors has overcome so many commutating and other motor troubles that it is now almost a universal practice.

Where commutators are not slotted, unless a highly abrasive brush is used the copper is worn away faster than the mica. The mica which then projects above the segment surface causes poor brush contact with the resulting sparking and flashing over. Flat commutators also result from the fact that the mica does not wear evenly at all points on the commutator. This trouble is entirely done away with by slotting the commutator. In addition to the elimination of troubles, a great saving is effected in maintenance costs by slotting commutators. A higher grade brush can be used, the brush-holder spring tension can be cut down and regulated with greater accuracy, and commutator wear can be reduced to a minimum. The brush tension, however, has to be closely followed, as track conditions play an important part, for too little tension will cause flashing on a rough rail.

BAY STATE STREET RAILWAY—DETAILS OF COMMUTATOR UNDERCUTTING ATTACHMENT

For a number of years the Bay State Street Railway has made it a practice to slot commutators, and for this purpose the commutator slotting device shown in detail on the accompanying drawings is used. This tool is mounted on the carriage of a lathe, the operator aligning and advancing the circular saw or miller by hand. The arbor on which the saw is mounted is driven by a 1½-in. belt, a friction pulley with counterweight keeping the belt tight throughout the operation.

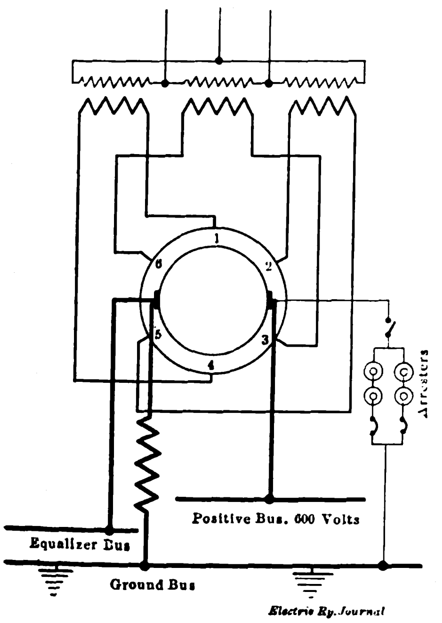
The saws used have twenty teeth, are 0.025 in. thick, and are made of special tempered steel. They can be purchased at very small cost, or manufactured in the shop, a large number being milled out on an arbor at one time and then tempered individually. As the copper dust and mica chips have proved troublesome, a small rotary suction fan has been installed. This fan gives very good protection to the operator.

On the average one man can slot one commutator an hour. After slotting care must be exercised to free the commutator from burrs and pieces of mica which, if not removed, would give a great deal of trouble. One saw will last approximately during the slotting of two to three commutators, depending on the hardness of the mica. It has been found that the use of a glass brush on slotted commutators, at every inspection of armatures in service, keeps the slots cleaned out and prevents carbon dust from accumulating, thus preventing a lot of trouble.

Aluminum Arresters Overcome Rotary Converter Flashovers

BY J. G. KOPPEL, ELECTRICAL SUPERINTENDENT OF BRIDGES, SAULT STE. MARIE, ONT.

In a newly-built substation, where the incoming voltage of 25,000 had to be stepped down and converted to 600 volts direct current, much difficulty arose due to flashovers from the positive to the negative brushes or to the frames of the three 500-kw six-phase diametrically-connected rotary converters. The exact cause of the disturbance was not determined, but it was observed that whenever a short-circuit occurred in the carhouse or repair shop, only 50 ft. distant from the substation, a big flashover followed on the rotaries. Sometimes these flashovers were so bad that we had to use a commutator stone to grind down the commutators to a smooth finish.



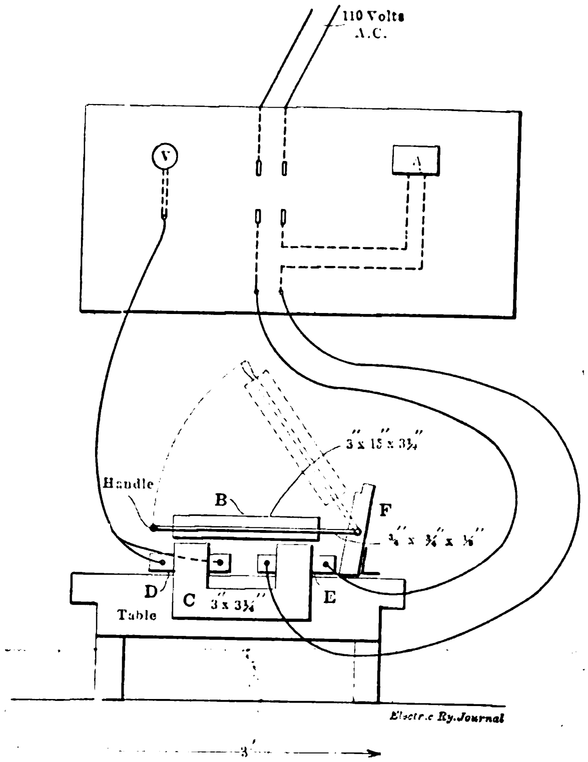
WIRING OF ROTARY CONVERTER SHOWING USE OF ARRESTERS TO OVERCOME FLASHOVERS

Our circuit breakers were of "Conduit" make with two trip coils. These breakers appeared to be in perfect order, and we thought that if a circuit-breaker was placed in the carhouse the troubles would stop. We did so, but the flashovers came as before. We then hit upon the plan of installing aluminum cell lightning arresters of the 300-volt type. The cells were connected between the positive terminal of each rotary and the ground bus, the connections being made as shown in the accompanying sketch.

We found that for a 500-kw unit the arrangement usually desirable was to employ four cells connected two in series with the two pairs of cells in multiple. A 30-amp fuse was inserted in series with each pair of cells in addition to the fuse between the ground bus and the parallel circuits formed by the cells. Since the installation of these arresters very little trouble has been experienced, and the only attention required is an occasional renewal of the arrester electrolyte. Their value is indicated by the phenomenon that during the operation of the rotaries a slight but almost continuous discharge may be observed between the two concentric plates of the arrester.

Field Coil Testing Apparatus

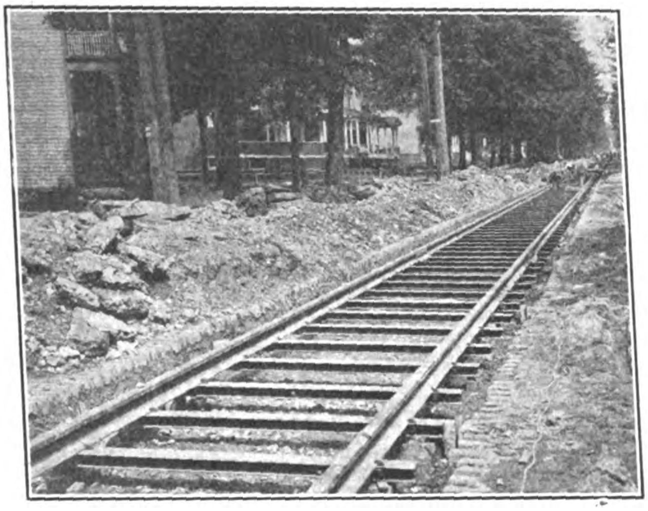
At the St. John Street shops of the Portland (Maine) Railroad Company, the field coil testing device shown in the accompanying drawing is in use, the apparatus having been made at the shops. A 110-volt, sixty-cycle, single-phase service is brought to a switch on a panel located on the wall, and an edgewise type ammeter is connected between one of the switch terminals and an exciting coil, *E*, which surrounds a laminated pole piece at the end of a core, *C*. The magnetic circuit is closed by letting an armature, *B*, drop upon the pole pieces after the coil to be tested, *D*, is dropped around the pole piece, as shown. This second coil is connected with a voltmeter, *V*, on the panel. If a coil is sound, full voltage according to a previously marked scale will appear on the voltmeter when the switch is closed, and the condition of the coil can also be detected by the sound of the laminations.



SKETCH OF FIELD AND TESTING DEVICE USED BY THE PORTLAND (MAINE) RAILROAD

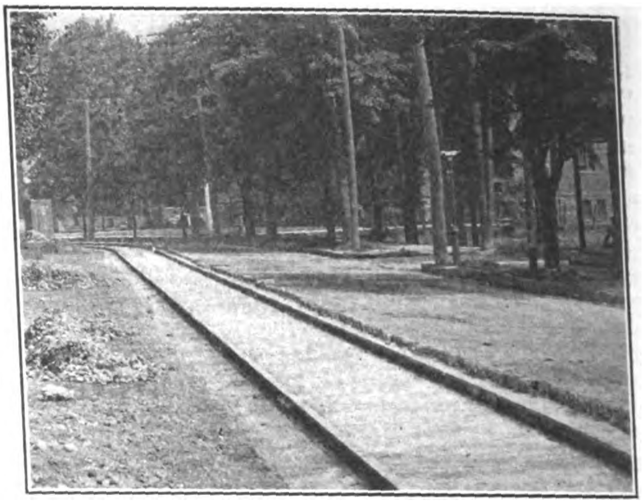
The Public Utilities Commission of Illinois has rendered an opinion to the effect that newspapers in Illinois cannot exchange advertising space for railroad transportation.

Steel Tie Construction at Buffalo



BUFFALO TRACK—READY FOR CONCRETE

The International Railway, New York, has recently completed 4¼ miles of single track with steel cross-ties throughout. The steel tie used is the Carnegie Steel Company's section M-24, I-beam shape, with base, 5 in.; narrow flange, 3 in.; depth, 3 in.; weight, 9½ lb. per foot. The ties were cut 6 ft. 6 in. long. The track was laid partly with 85-lb. A. S. C. E. rail and partly with Lorain section 116-434 girder rail. All mechanical joints were of continuous type. The tie fastening, which is known as the "Carnegie No. 25-A," is illustrated in an accompanying drawing. This fastening is simply a bolt with a head resembling a spike head, the nut and washer being secured to it under the flange of the tie. A fastening of this kind was used because the paving made it necessary to get all the depth possible.



BUFFALO TRACK—CONCRETED FOR BRICK PAVING

The spacing of the ties is 30 in. center to center, except at joints where it was reduced to 24-in. They were laid in a solid block of concrete, 8 ft. 6 in. wide to a depth of 8 in., or 5 in. under the bottom of the tie. The concrete mixture consisted of one part cement, three parts sand and eight parts gravel, mixed with a Foote 1-yd. mixer. This track was laid on Delaware Avenue, from the city line to Young Street, Tonawanda, N. Y., and on Ferry Street, Buffalo, N. Y., from Fillmore Avenue to Bailey Avenue. The latter section was laid with girder rails and welded joints. Of the three accompanying halftones, one shows the fastening, a second the track laid ready for concrete and a third the track concreted ready for paving, which was of brick throughout.

The work was designed and the construction was under direct charge of H. L. Mack, superintendent of track and lines, International Railway.

Comparison of Maintenance of Way Expenditures on the New Haven

Aggregate maintenance expenditures in the past year on the New York, New Haven & Hartford Railroad were $19,220,522, an increase of $1,726,764, or practically 10 per cent. It has been said that such expenditures as were made during the past year were needed to put the property in good shape physically. The ratio of maintenance to gross revenues was 28.86 per cent against 25.49 per cent in 1913 and 22 per cent in 1912. Expenditures on way per mile of road were the largest ever, amounting to $4,156, an increase of $517, or 13 per cent over 1913 figures. A four-year comparison of maintenance of way expenditures reduced to per mile of road and per mile of track follows:

	1914	1913	1912	1911
Maintenance of way...	$8,149,288	$7,238,113	$6,211,288	$6,398,854
Per mile of road......	4,156	3,639	3,122	3,215
Per mile of track.....	1,853	1,625	1,415	1,467

Shortage of Arc Lamps and Carbons in England

The *Engineer*, of London, says that the war has shown the extent to which England has depended upon Austria and Germany for its supply of arc lamps and carbons. Before the war began there was only one firm in Great Britain regularly engaged in this business. That firm built its carbon factory twelve years ago and "owing to persistent price cutting on the part of foreign competitors it has had on its own acknowledgment to face a loss of over £70,000." Since the war commenced the demand on the English factory has been enormous. In less than a week the firm could have sold a year's output.

Portable Concrete Houses

The growth of the use of reinforced concrete for small buildings, such as waiting stations, telephone booths, outhouses, switchmen's shelters and the like has been seriously handicapped in the past by the question of price, although the losses through incendiarism or rapid deterioration in the case of small unoccupied wooden buildings have been considerable. Recently, however, the manufacture of concrete houses on a large scale in specially-equipped factories has effected an astonishing reduction in the first cost, and this has now reached the point where the concrete structure with all its advantages of long life, absence of repair charges, neat appearance and fireproof construction, is actually cheaper than a similar wooden building.

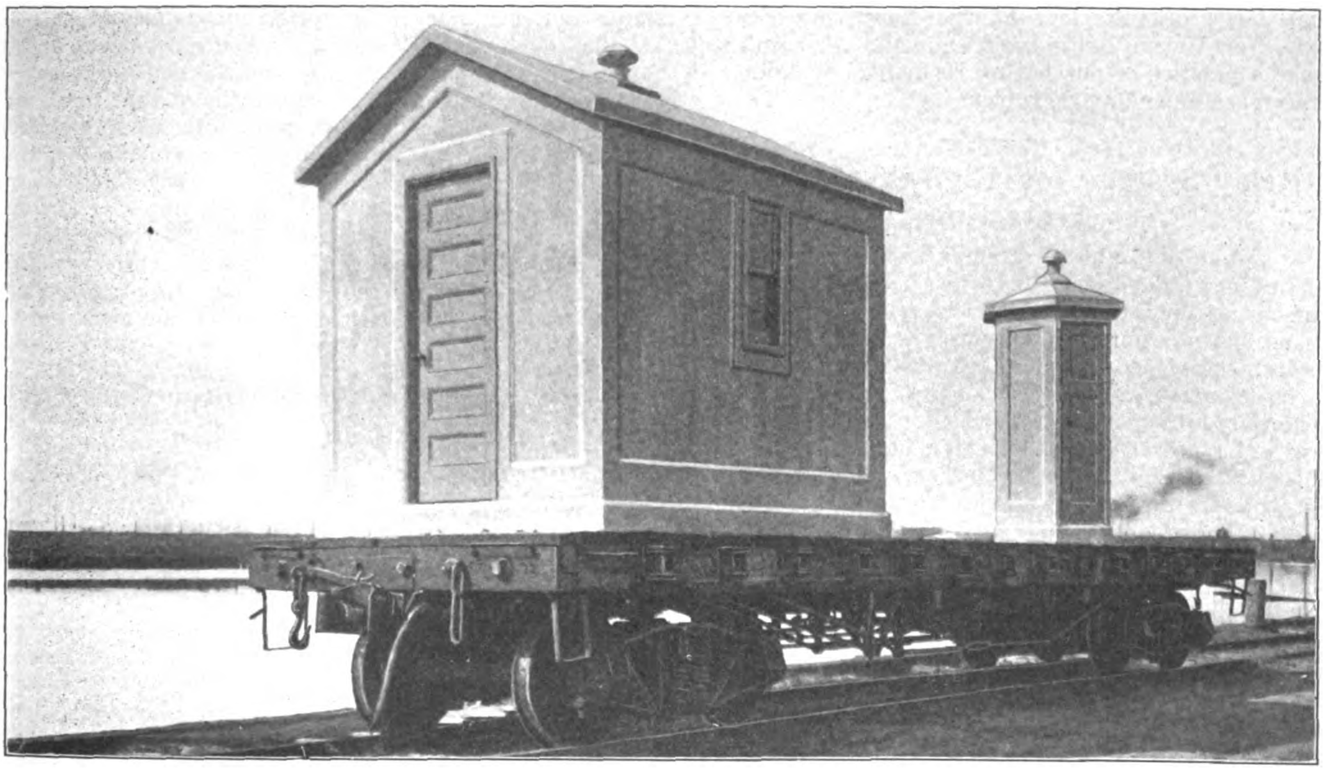
To cite an example: A well-built wooden waiting station, 8 ft. x 10 ft. in dimensions may be expected to cost, when built by a railway company, about $250 exclusive of overhead charges. A portable concrete house of the same size sells at the factory for $200, and as the latter structure is monolithic it can be unloaded from a freight car and leveled in position at any desired point with a minimum of labor. It is claimed that $25 should cover this expense under all ordinary circumstances, so that the use of concrete may be expected to effect a saving of about 10 per cent in first cost alone. The cost of freight is a negligible item as the houses are built in a dozen different parts of the country. The rate in the vicinity of Chicago, for example, is approximately 5 cents per hundredweight per 100 miles.

Among the electric railways which have been quick to grasp the economies resultant from the use of reinforced concrete for the numerous small buildings that are required for various purposes is the Lackawanna & Wyoming Valley Railroad, and the accompanying illustration shows two of the widely different types of portable concrete structures that have been purchased by the road.

One of the concrete structures is intended for housing a train-staff machine and the operator in charge at the end of a stretch of gauntlet track in a long tunnel. The other is intended for an outhouse. Both houses, as will be seen, have been loaded upon a flat car for shipment, and this illustrates one of the most remarkable features inherent in the design. The buildings are handled on and off the cars by a derrick or crane just as if they were solid, the line from the boom of the crane being passed through the hole for the ventilator in the middle of the roof and attached to a block of wood that distributes the strain along the ridge of the roof. The weight of the 8-ft. x 10-ft. house shown in the illustration is 20,000 lb., the small octagonal structure which is 4 ft. in diameter weighing 4400 lb.

As the houses are provided with floors that are homogeneous with the walls they may be set down anywhere without elaborate foundations, and they can be readily moved from place to place in case the necessity arises. The reinforcement, which consists of bars in the larger houses and bars and mesh in the small ones, is carried across the floor and roof so that there is no danger of cracks caused by uneven settlement. In general the roofs of rectangular buildings are made up of a grid of reinforcing bars, the octagonal houses, which are made in sizes ranging from 4 ft. up to 7 ft. 6 in. in diameter, having the reinforcement extend radially from a ring at the top of the roof.

No paint is applied either externally or internally nor is it ever necessary to paint these structures. The finish is made smooth and white in manufacture so that the appearance is exceptionally neat. Waterproofing is effected by using a rich mixture of concrete and in addition by introducing a special waterproofing compound while the mixing is going on. No leakage of water either through the roof or through the sides has been experienced. The walls of the large-size houses are approximately 4 in. thick, the floors being 3 in. thick and the roofs tapering from 4 in. down to 3 in. For the small houses these thicknesses are re-



MONOLITHIC CONCRETE STRUCTURES READY FOR SHIPMENT TO THE LACKAWANNA & WYOMING VALLEY RAILWAY duced in proportion, the sides approximating 2½ in. in thickness.

As mentioned above the cost of an 8-ft. x 10-ft. monolithic concrete house is about $200, but in the smaller sizes the costs are even lower in proportion. The price of the 4-ft. octagonal house shown in the illustration is only $65 and that of an octagonal house 7 ft. 6 in. across the flats, which is specially designed for interurban waiting stations, is $150. These prices include doors and windows, which can be made with metal frames if necessary, and any desired equipment may, of course, be installed, telephone booths, for example, being furnished with a shelf, a drawer for train orders, and suitable entrances for wires; oil houses having tanks and self-measuring pumps and watchmen's shelters being equipped with movable sash, a seat and a coal box. Practically any design of house can be supplied as the manufacturer, C. F. Massey Company, New York and Chicago, keeps a large variety of standard forms available for casting the buildings in monolithic form. It is interesting to note that even such large organizations as the New York Central, Erie, New Haven, Baltimore & Ohio and other railroads make a practice of purchasing ready-made buildings in preference to making their own.

Relay System for Highway Crossing Protection

A system of highway crossing signal protection involving new relay apparatus which may be adapted to a number of operating requirements in connection with an oscillating contactor attached to the rail has been recently developed by the Protective Signal Manufacturing Company, Denver, Col. The system meets four general requirements as follows: For single-track crossings, (1) no cut-out at crossing—highway bell permitted to ring out predetermined time, and (2) bell cut out when train reaches crossing. For double-track crossings, (1) movements only in direction of current of traffic, bell cut-out at crossing, and (2) movements in both directions on both tracks, bell cut out at crossing.

With a simple single-track crossing, when no cut-out at the crossing is desired and the highway bell is to be permitted to ring out a predetermined time, a train passing over either of the oscillators which are secured to the rail at the point from which the indication is desired opens the line circuit to the relay, de-energizing the relay coils and dropping its armature, which closes the bell circuit. The instant that circuit is closed through the bell magnet coils and the bell armature is drawn to its poles, the time element ratchet wheel is propelled around one tooth and through its contacts opens the line circuit to the relay and keeps the local or bell circuit closed. This continues until the time wheel has completed its set time and its contact cam is again brought in contact with the contact brush of the relay circuit, closing the line circuit and opening the bell circuit ready for another operation. Any desired ringing time can be given up to two minutes and forty seconds, the proper time being determined by speed and length of trains.

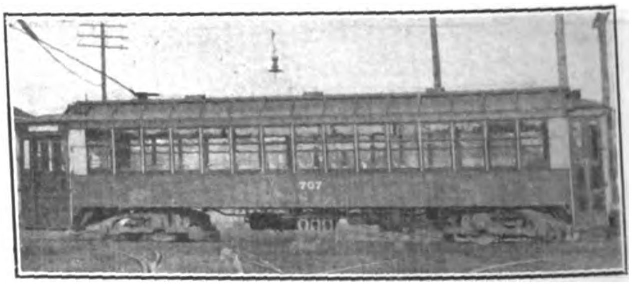
With a simple single-track crossing with a cut-out for the bell when the train reaches the crossing an additional cut-out oscillator at the crossing is connected direct to the terminal board and thence to the cut-out relay in the time unit. In this case the bell rings after the train passes over the first distant oscillator until it reaches and passes over the cut-out oscillator at the crossing, at which moment the cut-out relay in the time unit is de-energized and its armature drops, picking up the line relay and opening the bell circuit through the brush on the stick coil of the time relay. This causes all operations in the time unit to cease and the bell to stop ringing. As the train proceeds and passes over the distant oscillator on the other side of the crossing, for movement in the opposite direction, the vibration of the line oscillator again opens the line circuit to the line relay and its armature is again dropped. This action closes the circuit to the time relay which immediately continues its operation until the time wheel has completed its set time and restores the line relay ready for the next operation without causing the bell to ring. The reason for the non-ringing is that after the bell circuit is once broken through the stick coil of the time relay by the cut-out oscillator at the crossing, it is not again picked up until the time relay has reset.

With double-track crossings, when movements are only in the direction of the current of traffic and cutting the bell out at the crossing is desired, the crossing is protected by a relay system nearly similar to that last mentioned, except that each track has only one distant oscillator and each track is protected independently.

With double-track crossings, when movements are in both directions on both tracks and the bell is cut out at the crossing, the connections from the distant line oscillators are the same as with the ordinary single-track crossing, and the installation and operation of this equipment is the same as with single-track where a cut-out is used, excepting that one common line wire and one bell for the two tracks are used. The interior wiring of the time unit is also somewhat different. Otherwise this installation would be the same as two independent single-track crossings with cut-out at the crossing.

Seattle Single-End Two-Motor Cars On 7 Per Cent Grades

The Puget Sound Traction, Light & Power Company placed in service during August, 1914, twelve new single-end prepayment cars of the type illustrated. These cars weigh 40,300 lb. each fully equipped, are 49 ft. 2 in. long over all, and seat sixty passengers. The equipment per car includes two Westinghouse 310-C motors, K-35 control, and two Standard No. 0-36 maximum traction trucks. The company had previously been under the impression that it could not economically operate anything but a four-motor equipment in Seattle owing to the heavy grades. It still has a number of lines on which it cannot operate a maximum traction truck, but it has others on which a car equipped with maximum traction trucks will maintain the same schedule as a four-motor equipment. After trying one car with such trucks, it purchased ten more in 1913 and twelve this year, making a total of twenty-two. The company operates these cars over a 7 per cent maximum grade.



SEATTLE SINGLE-END TWO-MOTOR CAR OPERATED OVER 7 PER CENT GRADE

News of Electric Railways

REPORT ON TRANSIT CONDITIONS IN ST. LOUIS

Summary of Recommendations Made by Engineer Harrop to the Missouri Commission and Comment of General Manager McCulloch

J. L. Harrop, engineer for the Public Service Commission of Missouri, has filed with the commission his report regarding the adequacy of the service rendered by the United Railways and the near-future transportation requirements of the city of St. Louis. His definition of adequate service is that it means the operating of enough cars to carry all who desire to ride, with a maximum degree of safety to both the passengers and to the traffic on the street, with a maximum degree of comfort to passengers in well-heated and well-ventilated cars, with the highest speed consistent with safety, over the shortest practicable routes, for a single fare to any part of the city, with a reasonable return to the company. He says that unless operating or financial conditions render it impossible or impracticable, seats should be furnished for all who desire to ride during the non-rush hours. From personal experience he found the existing transfer system in St. Louis to be very satisfactory.

Other recommendations made by Mr. Harrop are as follows:

"That an ordinance be enacted making it a misdemeanor for vehicles to use the street railway tracks when there is sufficient room on the sides for their passage.

"That the city establish additional safety zones as a measure to promote safety and convenience of the people who use street cars.

"That the practice of pedestrians crossing street intersections diagonally be prohibited.

"That all of the company's cars be equipped with forced ventilation heaters or other equally satisfactory heating device ready for service during the winter of 1915-1916."

In answer to complaints that cars were unsanitary and dirty the report says:

"The examination of hundreds of cars in operation and just leaving the carhouses showed the cars to be in excellent sanitary condition."

The company is commended for its action in beginning to equip car platforms with sliding doors and folding steps so that the platform is completely closed while the car is under way.

With reference to the track conditions, Mr. Harrop says:

"A careful examination of all the tracks shows, in general, that their physical condition is good. There are, of course, and always will be on a system of this size, pieces of track that are in poor condition."

The practice of certain manufacturers of dismissing some of their departments at 5 p. m., others at 5:15 and others at 6 p. m. is strongly commended by Mr. Harrop as tending to lessen the congestion at the peak. Comparing the speed at which the United Railways cars are operated, Mr. Harrop finds that it is fully up to the standard maintained on the street railways in Cleveland, Detroit, Milwaukee, St. Paul and Minneapolis. He says that the cars of any street railway system should be operated at the highest speed consistent with safety. He finds that the average number of passengers carried monthly during 1912 was 29,800,000, in 1913 31,400,000 and during 1914 31,600,000. The service furnished during the months of the traffic survey—June, July and August—was found to be excellent, and the "safety first" movement recently inaugurated is highly commended. He finds that the "owl" car service, generally speaking, is entirely adequate. Observations in the downtown districts show that there is considerable congestion at some street intersections during the morning and evening rush-hour periods. To alleviate this condition additional loops are recommended for construction during 1915, 1916, 1917 and 1918. There are a number of proposed extensions which are not recommended, but which are set out in the report. For various reasons it is said that it is not deemed advisable to recommend them at this time.

Richard McCulloch, vice-president and general manager of the United Railways, is quoted in part as follows:

"The report of J. L. Harrop, the engineer of the Public Service Commission, gives evidence of the thoroughness with which the observations were conducted. Of course, I have not seen the official report as yet. The question of 'adequate service,' which we are compelled to maintain, depends on what is a car load.

"The very things Mr. Harrop recommends regarding the downtown loops we have had in mind for a long time. We have had the matter up with the Board of Public Improvements, but were denied the privilege of making the changes. The board held it could not issue the necessary permits to lay new tracks and could only give us permission to connect tracks with curves and switches when the tracks were already down. Now, with the recommendation from the State Board, I trust it will be a simple matter to obtain the necessary franchises. The plan for the loop of the Hodiamont line conforms exactly to what in my estimation would be the best thing possible. All of the changes which have been recommended in regard to the loops are for the better, and if we are permitted the privilege of carrying out the recommendation, the downtown congestion will be relieved."

NEW INCOME TAX RULE

The commissioner of internal revenue, with the approval of the Secretary of the Treasury, has amended the income tax regulations so as to enable corporations to make income tax returns for fiscal years under which they operate instead of for the calendar year. In order to take advantage of this ruling, a corporation must give notice in writing to the collector of internal revenue for the district in which the corporation is situated at least thirty days prior to March 1 that it has designated the last day of some month as the close of its fiscal year. The fiscal year so designated must cover a twelve-month period. The regulation on the subject issued by the commissioner of internal revenue to the collectors of internal revenue is as follows:

"Reference is made to Treasury Decision No. 2001, relative to the designation by corporations of a fiscal year other than a calendar year as a basis for making returns of annual net income.

"You are informed that every corporation amenable to the income tax law in existence at the close of the calendar year is required to file a return to cover all or any part of the preceding calendar year during which it may have been in existence on or before March 1, provided such corporation has not established or does not establish a fiscal year.

"In order to establish a fiscal year it is necessary for the corporation to give notice to you in writing designating the last day of some month as the close of its fiscal year. This notice must be filed not less than thirty days prior to March 1 of the year in which the fiscal year period of twelve months closes. A return for that portion of the calendar year preceding the commencement of the fiscal period of twelve months is required to be filed on or before March 1 of the year next following the calendar year of which it is a part, and the return for the first full fiscal year is required to be filed on or before the last day of the sixty-day period following the close of the fiscal year.

"Example: A corporation desiring to establish its fiscal year as ending on June 30, 1915, must file notice not less than thirty days prior to March 1, 1915, or on or before Jan. 29, 1915. A return for the period Jan. 1 to June 30, 1914, must then be filed on or before March 1, 1915, and a return for the first fiscal year period (July 1, 1914, to June 30, 1915), must be filed on or before Aug. 29, 1915.

"That portion of the year preceding the beginning of an established fiscal year is held to be a fractional part of the calendar year, and as the return of a calendar year is not required to be filed until on or before the first day of March next following, there is no provision of law whereby the return covering a fraction of a calendar year is required to be filed earlier than 'on or before' the next March first, though it is preferred that the return for this fraction shall be filed as early as possible after the close of the period.

"The above instructions are supplemental to Treasury Decision 2001, and rulings or decisions heretofore issued in conflict with the foregoing are hereby revoked."

ANNUAL NEW HAVEN MEETING

The Report Includes References to Costs of the Electrified Division, Increase in Power Station Capacity and Probability of Buying Central Station Energy

The annual meeting of the stockholders of the New York, New Haven & Hartford Railroad was held at New Haven, Conn., on Oct. 28. Benjamin Campbell, Frank W. Matteson, J. B. Russell, Eli Whitney and Harris Whittemore were elected directors to succeed William Rockefeller, George F. Baker, John L. Billard, Morton F. Plant and William Skinner.

At the meeting the report of the company for the year ending June 30, 1914, was presented. This report in pamphlet form contains 112 pages dealing with the activities of the company. The general remarks of Howard Elliot, chairman of the board of directors and president of the company, dealt with the related subjects of operating results, additions and betterments, the work of affiliated companies, the electrical department and the changes in the scheme of organization of the company. In addition a review was presented of the negotiations with the department of justice of the United States regarding the segregation of the various companies, and the results were appended of the court decree entered into between the company and the department of justice, as noted in the ELECTRIC RAILWAY JOURNAL of Oct. 24. Mr. Elliott said that in order to obtain a complete and thorough history of the charters, mortgages, leases and the character of the different securities of the company, a thorough investigation was made of all the papers and that a most complete history of this part of the system had been prepared for use as a basis during the coming year for drawing up a financial plan intended to permit the refunding of the companies' floating debt if the necesary legislation can be obtained. Mr. Elliot also referred to the change in the status of the electric railways and to their being given independent organizations separate from the New Haven with complete staffs of officials, all of whom gave their entire time and attention to their respective properties. He said that this was expected to result in greater efficiency. The summary of the earnings of the various electric railway properties as contained in the report was published in the ELECTRIC RAILWAY JOURNAL of Aug. 31. In referring to electrical department of the company Mr. Elliot said in part:

"Between New York and New Haven, including all yards and sidings, and the Cedar Hill yard at the latter point, the company has 518 miles of track equipped for electrical operation, excluding that part of the New York Central company between Woodlawn and Grand Central Terminal used under lease but maintained by that company. The volume of passenger and freight business moving between New Haven and New York is very heavy and the necessity for the most effective organization is very essential.

"The investment in the electrification between New York and Cedar Hill in power, locomotive, transmission lines, distributing system, electrical shops, when all the business is handled electrically, will be about $20,000,000.

"For the purpose of supervising closely and making the most effective use of these large investments and because the operation and maintenance of this extensive electrical installation is very technical, an electrical department was organized on March 18, 1914, consisting of a consulting electrical engineer, with necessary assistants, having advisory jurisdiction over matters pertaining to the engineering, construction and operation of the electrical system and equipment. Better results are being gradually obtained by having this new department act in co-operation with the divisional operating officers.

"The electrification of the Harlem River and Van Nest yards, including all freight sidings west of Stamford, has been completed and electric switching, including freight service, inaugurated in these yards.

"The installation of machinery in the shops at Van Nest was completed and the transfer of the heavy repair work on electrical equipment from Stamford to Van Nest was made in September, 1913. The increased facilities offered by these shops has resulted in a marked improvement in the maintenance of electric equipment, and should effect a decrease in costs.

"The electrification of main line tracks, the freight yards at South Norwalk and Bridgeport, and the sidings at intermediate points, has been completed and placed in operation, commercial passenger service having been inaugurated on June 22, 1914. At present forty passenger trains are being operated electrically between New Haven and New York, and approximately sixteen freight trains are being hauled daily by electric locomotives between Harlem River, Bridgeport and New Haven. This includes approximately 50 per cent of the passenger train service between Stamford and New Haven on week days and on Sundays the entire passenger train service.

"The present eastern terminus of the electric zone is at New Haven. The extension to Cedar Hill will be completed and put into service some time in October, when the transfer from steam to electric motive power will be made at Cedar Hill.

"The electric haulage of freight trains should result in increasing the capacity of this part of the road, and giving beetter service to the public.

"The new system of electric power distribution was inaugurated in January, 1914, resulting in the practical elimination of disturbances in the circuits of the telephone and telegraph companies paralleling the electric zone and in improved conditions of operation in the railway circuits.

"Power for operation in the New Haven's electrification zone is provided from the company's Cos Cob power station. The capacity of the Cos Cob power station has been increased from 15,000 kw to 35,000 kw, this work having been completed during the year. Steps are now being taken to increase the output at Cos Cob, and to purchase power from the New York Edison Company on such terms as will justify the company in deferring the outlay of capital for that purpose. With this additional power the maximum use of the electrical installation can be made with the electric locomotives now owned by the company."

The report also gives the first published figures on the cost of maintaining the electric locomotives used on the main line. This cost for 1914 covers 102 units which made runs totaling 2,913,000 revenue-miles, giving for 1914 a maintenance cost per electric locomotive-mile of 18.2 cents. The corresponding figures for 1913 were eighty-five units in service, which made 2,430,000 revenue-miles and were maintained at a cost per mile of 13.3 cents.

CONFERENCE OF MAYORS ON PUBLIC UTILITIES

The program has been issued for the conference of American mayors on public policies concerning municipal utilities to be held in Philadelphia on Nov. 12 to 14. The conference was called by Mayors Blankenburg of Philadelphia, Mitchel of New York, Harrison of Chicago, Baker of Cleveland and Shroyer of Dayton. A reception to visiting mayors will be held on the evening of Nov. 12 at the Bellevue-Stratford Hotel. Governor Tener of Pennsylvania is to make an address of welcome.

The first business session will be held at the Bellevue-Stratford Hotel at 10:30 a. m. on Friday, Nov. 13. The general subject is "Practical Utility Problems." Mayor Blankenburg will preside. The following addresses are on the program: "Fundamental Planks in a Public Utility Program," by Delos F. Wilcox, franchise expert, New York; "The Regulation of Municipal Utilities," by Nathaniel T. Guernsey, general counsel of the American Telephone & Telegraph Company, New York; "Philadelphia's Transit Problems," A. Merritt Taylor, director of city transit, Philadelphia; "Municipal Lighting Rates," by Ray Palmer, commissioner of gas and electricity, Chicago, Ill.; "Laborers' Interest in Public Utilities," open discussion.

The program for the afternoon session, on the general subject of "Regulation of Utilities," is as follows: "Some Present-Day Issues in Regulation," by Prof. Edward W. Bemis, board of supervising engineers Chicago Traction; "What Certain Cities Have Accomplished Without State Regulation," by Stiles P. Jones, secretary Voters' League, Minneapolis, Minn.; "A Constructive Policy for Public Service Corporations," by Charles Day, of Day & Zimmermann, Philadelphia; "What Regulation Must Accomplish if It Is to

Be Permanent," by John M. Eshleman, president of the Railroad Commission of California. The third session, under the auspices of the American Academy of Political and Social Science, is to be held at the Central High School at 8:15 p. m. on Nov. 13 and is to be devoted to local and state regulation of municipal utilities. Mayor Mitchel of New York is to preside, and addresses are to be heard from Halford Erickson, Railroad Commission of Wisconsin; Milo R. Maltbie, Public Service Commission of the First District of New York; Charles E. Merriam, professor of political science, University of Chicago, and Ira W. Straton, Mayor of Reading, Pa.

The fourth session is to be at the Bellevue-Stratford at 10:30 a. m. on Nov. 14 and is to be on municipal ownership and operation. Mayor Baker of Cleveland will preside. An address on "Municipal Ownership—the Testimony of Foreign Experience," will be made by Frederick C. Howe, commissioner of immigration, New York. Fifteen-minute reports will be heard from managers of typical municipal plants. There will be an open discussion led by Clarke M. Rosecrantz, of general counsel of The Milwaukee Electric Railway & Light Company, and Congressman Robert Crosser of Ohio. The fifth session, in the afternoon, will be executive and open only to mayors and delegates. There will be a round-table discussion on "elements in a constructive utility program."

The sixth session will be held at Witherspoon Hall under the auspices of the American Academy of Political and Social Science on the evening of Nov. 14 and will be devoted to holding companies and the public welfare. Secretary of the Interior Franklin K. Lane will preside. Addresses will be made by Francis T. Homer, of Betron, Griscom & Company, New York; Charles F. Mathewson, counsel of the Consolidated Gas Company, New York; James P. Goodrich, director of the National City Bank, Indianapolis, Ind., and Louis D. Brandeis, Boston.

So far the mayors of 124 cities have indicated their intention of attending the conference in person or by delegate. Delegations have also been appointed by civic organizations and public service commissions.

The program contains a reference to the Utilities Bureau, organized by the mayors who called the conference. The purposes of the bureau are given as follows: (1) To serve as a national agency through which American cities may co-operate in exchanging data as to rates, service standards and cost factors in municipal utilities; (2) to advise cities as to the best plans and methods for their utility campaigns; (3) to publish and disseminate information pertaining to service standards, rates, franchises, public contracts, and any and all other matters of interest and value to the public regarding the operation, construction, maintenance and regulation of public utilities; (4) to assist, upon request, in the proper and adequate presentation of the interests of the city and the public in hearings on utility matters before public service commissions or other regulative or judicial bodies. The trustees are Louis D. Brandeis, lawyer, Boston; Frederick A. Cleveland, political economist, New York; S. S. Fels, manufacturer, Philadelphia; Felix Frankfurter, professor of law, Harvard University; Charles F. Jenkins, proprietor of the *Farm Journal*, Philadelphia; Leo S. Rowe, professor of political science, University of Pennsylvania; Frederick W. Taylor, consulting engineer, Philadelphia, and Charles R. Van Hise, president of the University of Wisconsin.

STREET RAILWAY QUESTION AN ISSUE IN DETROIT

Notwithstanding that the Detroit (Mich.) United Railway is operating under a day-to-day arrangement with seven-for-a-quarter tickets and that an appraisal is now being conducted with a view to purchase by the city of the company's properties within the one-fare zone, the street railway question is again an issue in the Detroit municipal elections. Mayor Marx, under whose administration the seven-for-a-quarter agreement was made, is campaigning with the plea that the street railway patrons have been saved thousands of dollars. His opponent, F. F. Ingram, charges that the agreement was a betrayal of the city's municipal ownership program; that it gave the company new rights in the streets where its franchises have expired, and that the rate of fare is higher than in any offer which the company has made for a settlement within a number of years. Mr. Ingram also contends that the agreement made under Mayor Marx has caused to a very large extent the elimination of the eight-for-a-quarter tickets in workingmen's hours because of the inconvenience of handling two sets of tickets. The election is to be held on Nov. 3.

Corporation Counsel Lawson has advised the Detroit Street Railway Commission that the title to the pavement between the tracks of the Detroit United Railway rests unequivocally in the city and that no allowance for the same should be permitted in the appraisal now under way. The company, in its reproduction value inventory filed with the commission last December, set a value of $1,154,720 on the pavement between the tracks. Mr. Lawson, in his opinion, points out that the Michigan Supreme Court in the Fort Street rental case ordered that in the event the company was required by the Common Council to remove its tracks from the streets it must place the pavement in its proper condition, and he relies upon this decree to bear out his opinion that the pavement between the tracks belongs to the city.

Service on the Junction Avenue portion of the new Grand Belt line in Detroit was inaugurated by the Detroit United Railway on Oct. 28. This line runs from Fort Street to Warren Avenue and connects with the Michigan, Baker and Crosstown lines. Operation has been held up several months pending a court decision as to the right of the company to install a clearance curve at Junction and Dix Avenues. Judge Murphy of the Circuit Court held that the company had not received specific authority from the Common Council for the curve and therefore could not construct it. The Common Council, because the clearance curve cut into the curb and sidewalk, refused permission, but granted the right for a non-clearance curve, the construction of which, however, will be held in abeyance for the present. It is estimated that 100,000 people will be served by this one section of the proposed belt line. People have been endeavoring for years to have the line constructed because they were without any adequate facilities, but it was not until this year that the company had the right conferred on it to build the line under the day-to-day agreement of Aug. 7.

Inasmuch as a seven-for-a-quarter fare obtains to all the limits of the city, the Detroit United Railway and the city, through counsel, have obtained a postponement for one year of argument before the United States Supreme Court in the cases brought by the company to determine whether or not it should extend one-fare privileges to Fairview Village and a part of Greenfield Township, both of which were annexed by the city. The State Supreme Court held that the company's contract called for the inclusion in the one-fare zone of all territory within the city limits.

THE NEW UNION STATION IN KANSAS CITY

The last week has seen much rerouting of street cars in Kansas City in preparation for the formal opening of the new Union Station one minute after midnight on Nov. 1. While the formal arrangements for rerouting are not wholly complete, cars were run over many new tracks in the neighborhood of the station. One of these new tracks immediately serves the station, the cars turning west on Twenty-fourth Street from Grand to Main Street, then north over a viaduct which heretofore has never been used. The Metropolitan Street Railway has double tracked its line on Walnut Street between Eighteenth and Nineteenth Streets and on Nineteenth Street between Main and Walnut Streets. The board of control completed before Oct. 26 its plans for rerouting in view of station travel, and submitted recommendations to the City Council, which has the authority, by ordinance, to route and reroute street cars.

The Metropolitan Street Railway has completed the new special work at Eighteenth Street and Prospect Avenue which was necessary for the rerouting of the Indiana line. This line had previously reached the business district by way of Eighteenth Street, and its exit had been by way of Nineteenth Street; both in and out it ran through one district of negro business houses and tenements; the residents served by the suburban part of the line where good homes have been built in the past few years desired the change so that they could reach town through the better class surroundings of Fifteenth Street, which is an unusually wide and beautiful thoroughfare.

One feature of the new Union Station in which the Metropolitan Street Railway is at present a factor and which has not yet been completed is the mail service to and from the Kansas City post-office. The mails are now carried between the depots and the post-office on special street cars, but there is no track by which the Metropolitan Street Railway can enter the new station grounds for the purpose of getting or delivering mail to trains or to station post-office facilities. Negotiations are said to be temporarily suspended between the Terminal Company and the Metropolitan Street Railway over the lease of station ground on which a track for mail cars might be built. The post-office officials are said to be considering the matter of using trucks for transporting the mails between the station and the post-office.

PROPOSED CANADIAN HYDROELECTRIC RAILWAYS APPROVED

Eleven municipalities out of the thirteen voting on the project carried the by-laws submitted on Oct. 19 authorizing their respective Councils to enter into contracts with the Hydro-Electric Power Commission of Ontario for the construction of the proposed Hydro-Electric Municipal Railway from Toronto to Newmarket and Port Perry. Newmarket and Uxbridge Township were the only corporations which voted not to support the scheme. According to Sir Adam Beck the next move of the municipalities is to secure from the Canadian government an assurance that the federal subsidy taken into account by the engineers in making their estimates of the cost of the line will be available. The general impression has prevailed that while the administration at Ottawa had given no formal answer to the request of the municipalities for a subsidy, little risk was being taken in proceeding with the votes. It is stated now, however, that no such assurance has been received. That a second vote would be necessary if the subsidy was not obtained was intimated by Sir Adam Beck during the campaign. The only way out would be by the preparation of new plans that would permit construction without the need of the subsidy. The Council of Goderich, Ont., has decided to ask the Hydro-Electric Power Commission to take up the matter of operating the defunct West Shore Railway as a hydro radial line.

CLEVELAND RAILWAY MATTERS

At their regular meeting on Oct. 24 the directors of the Cleveland (Ohio) Railway decided that, with the approval of the Council, all the money found in the fare boxes on the day before Thanksgiving above the amount found on the same day last year be turned over to the Associated Charities to meet the $35,000 deficit that now exists. John J. Stanley, president of the company, said that this money will be given only in recognition of the peculiar position the organization occupies in the community and the exceptional demands that have been made and will be made upon it.

An indictment was returned by the Cuyahoga County Grand Jury on Oct. 21 against George A. DeGraff on the charge of obtaining money under false pretenses from the Cleveland Railway. He is charged with receiving $500 damages on the claim that his spine was fractured by a fall from a Cedar Avenue car last January. At the same time Dr. Sidney J. Havre and Dr. Charles D. Triester were placed under indictment on the allegation that they represented that the X-ray photograph of the fracture showed it to be a recent injury, whereas it is claimed by the prosecution that the injury was suffered eight years ago.

On Oct. 21 Judge Estep of the Common Pleas Court upheld the rule of the company prohibiting passengers from standing on the rear platform of cars. Joseph Nesper had brought suit against the company for $5,000 because he was ordered off the rear platform of a car by the conductor.

It seems likely that the arbitrators who are to pass on the demands made by the motormen and conductors of the Cleveland Railway will have some trouble in deciding upon the points at issue. Judge Willis Vickery, representing the men, says that the question of the eight-hour minimum work day is one of the points to be decided. Under the contract between the company and the union it is claimed this point cannot be raised. The company offered a nine-hour day and an increase in wages in order to meet the men half-way, but seemingly the contract, as viewed by the company, does not provide for raising this point in case of arbitration.

WESTERN MASSACHUSETTS TRANSPORTATION HEARINGS

At a continued hearing at Worthington, Mass., by the legislative commission on transportation facilities, Calvin Coolidge, president of the State Senate, expressed the hope that something might yet be done to secure electric railway extensions in the Berkshire district through the New York, New Haven & Hartford Railroad. The speaker said that in his opinion questions of monopoly could not be raised in the case of electric railway extensions into new territory for the purpose of feeding the existing steam railroad lines, and he suggested that an appeal be made to the New York, New Haven & Hartford Railroad to carry into effect its former plans with respect to electric railway extensions in the hill towns of western Massachusetts. Mr. Coolidge said that he believed that the federal government has no objection to the continued ownership of the Berkshire Street Railway by the New Haven company, and he advanced the view that the company would probably be willing to undertake the extensions in due course. The speaker condemned state buildings and ownership of short electric railway extensions. Another speaker, in pointing out the need of electric railway facilities, stated that it costs $4 a ton to ship freight by gasoline trucks over the highway from Cummington to Williamsburg, a distance of 10 miles. At present it is impossible to go to Springfield and return on the same day from that section of the Berkshires.

BOSTON TRANSPORTATION HEARINGS

Hearings were resumed during the week ended Oct. 31 by the Massachusetts Public Service Commission upon transportation service in the Boston metropolitan district. A general sentiment developed on behalf of the proposed consolidation of the Boston Elevated Railway and Bay State Street Railway. In order to counteract the impression that the consolidation would result in the extension of 5-cent fares to all parts of the district, Chairman McLeod informed representatives from Waltham, Watertown, Stoneham, Revere, Chelsea and other points wholly or partially outside the Boston Elevated system that there must be no delusion to the effect that the establishment of a single system would mean a straight 5-cent fare everywhere within its confines. He said that there is a limit beyond which passengers cannot profitably be carried for 5 cents. Regarding the traffic conditions at the Boston Elevated Dudley Street Station, Mr. McLeod said that the commission realized the importance of the transportation problem in the Dudley Street region, and that an engineer of the board has been assigned to study the conditions and report his findings. Discussing transportation facilities between Stoneham and Boston, A. S. Parker, of Stoneham, pointed out that since the establishment of through car service via Middlesex Falls and Sullivan Square by the Bay State and the Boston Elevated companies, most of the competing steam service of the Boston & Maine Railroad on the Stoneham branch has been withdrawn. A representation from the town of Arlington advocated the operation of surface cars in trains from Arlington to Boston via the Cambridge Subway and Dorchester tunnel upon the completion of the latter. The railway companies will be heard later.

Arbitration Board at Lexington.—The board of arbitration formed at Lexington, Ky., to pass on the dispute between the Kentucky Traction & Terminal Company and the carmen's union growing out of the discharge of Motorman Robert E. Walker has been completed by the appointment of Judge W. B. Smith, a lawyer of Richmond, Ky., by Governor James B. McCreary. George McLeod represents the company and Robert G. Ross the carmen.

Municipal Street Railway Inspectors.—The Civil Service Commission of San Francisco, Cal., has announced that an examination will be held on the evening of Oct. 31 to secure candidates for promotion by the San Francisco Municipal Railways from the ranks of motormen and conductors to the rank of inspector. The subjects of the examination and the relative weights on a scale of 100 are: general knowledge of duties, 50; writing of reports, 25; arithmetic, 10; experience, 5; ascertained merits, 10.

A Decade of Subway Operation in New York.—On Oct. 27, 1904, three special trains containing Mayor McClellan and other officials of Greater New York left the Brooklyn Bridge station for the initial trip through the New York subway preparatory to the first section of the system being placed in regular operation. On Jan. 9, 1908, the extension under the East River to Brooklyn was opened. Originally designed to carry 600,000 people a day the subway system now, ten years after its inception, is averaging more than 1,000,000 passengers a day.

The New Haven Grand Jury Inquiry.—The special Federal Grand Jury which has been investigating the affairs of the New York, New Haven & Hartford Railroad was excused at the end of its session on Oct. 26 until Nov. 1. The Grand Jury was summoned to investigate responsibility for the acts of the company, which according to the government amounted to a violation of the Sherman law by the railroad, its subsidiaries and its directors. Of the witnesses who have been called before the Grand Jury only one, Charles S. Mellen, former president, has ever been a director. No statement has been made in regard to the purpose of the Department of Justice at Washington with respect to the preparation of indictments in this case.

Proposed Rapid Transit Road at Cincinnati.—The Rapid Transit Commission, with the convention hall commission and representatives of the Cincinnati Traction Company, inspected the proposed route of the rapid transit road in Cincinnati on Oct. 20, in order that the commission might secure a better idea of the work it will be called upon to perform. Frank Krug, city engineer, and F. B. Edwards, a subway engineer, were also members of the party, while a rapid transit engineer, Mr. Drum, accompanied Walter A. Draper, vice-president of the Cincinnati Traction Company. The loop near Fountain Square will probably be placed underground and a combined station and convention hall will be built in this vicinity. The convention hall commission has thus become interested in the rapid transit proposition.

Suit in Tacoma Over Franchise Terms.—The Old Colony Trust Company, Boston, trustee under the mortgage securing the $1,500,000 of bonds of the Tacoma Railway & Power Company, a subsidiary of Puget Sound Traction, Light & Power Company, has secured from the federal court an order restraining the city of Tacoma from removing trolley wires and poles of the street railway company. A similar order asked by the Puget Sound Traction, Light & Power Company was denied. A controversy over the right of the company to occupy the streets with its poles and wires has existed for some time and a friendly suit was agreed upon to test the question. Within a day after the bringing of the suit the Council revoked the franchise of the company despite an agreement with the trustee for the bonds that the franchises would not be interfered with.

Municipal Operation Outside Corporate Limits.—Scott Z. Henderson, assistant attorney general of Washington, in an opinion to the State Bureau of Inspection holds that cities are not authorized to buy or operate street railway systems outside of their own corporate limits and that municipal corporations cannot legally levy a tax for such purposes. This opinion, it is announced, affects the Highland Park & Lake Burien Line, Division "C," of the Seattle Municipal Railway, as practically half of this road lies outside of the city limits of Seattle. Mayor Gill recently stated that it may be necessary for Seattle to go before the next Legislature to obtain permission to operate a street railway outside the city limits. The Lake Burien line extends from Riverside and California Avenue, west of the Duwamish drawbridge to Lake Burien, a distance of about 9 miles, 4½ of which is outside of the limits of the municipality.

Past-President Black Wins the Bag.—Those who attended the recent A. E. R. A. convention in Atlantic City are probably wondering who won the genuine walrus traveling mag offered by the National Tube Company to the person estimating the weight of its exhibit at the convention. The company now announces that the combined weight of its exhibit, boxed and ready for shipment, was 12,595 lb. The three nearest estimates were as follows: 12,600 lb., Charles N. Black, vice-president and general manager of the United Railroads of San Francisco; 12,585 lb., Charles E. Coleman, manager of the Mica Insulator Company, Chicago, Ill.; 12,575 lb., H. B. Chamberlain, salesman with the Transportation Utilities Company, New York. The bag was, therefore, awarded to Mr. Black, whose estimate was most nearly correct, winning over Mr. Coleman by a margin of 5 lb. Several hundred estimates were made.

Massachusetts Street Railway Association.—At the regular monthly meeting of the Massachusetts Street Railway Association at Young's Hotel, Boston, on Oct. 21, with President H. H. Crapo, New Bedford, in the chair, an informal address upon the signs of the times was delivered by W. J. Clark, manager of the heavy electric traction department of the General Electric Company. Mr. Clark delighted his audience by many personal reminiscences of the early days of electric traction, and after passing to present problems discussed the economic disadvantages of government ownership. The rest of the meeting was occupied with comments on the recent Atlantic City convention. Among the speakers were C. V. Wood, Springfield, Mass.; H. B. Potter, Boston; John T. Conway, Brockton, Mass., and Howard F. Eaton, Plymouth, Mass. The last speaker emphasized the importance to electric railways of following the tendencies in workingmen's compensation legislation during the coming winter.

Appreciative Editorial Tribute.—J. Brodie Smith, vice-president and general manager of the Manchester Traction, Light & Power Company, Manchester, N. H., who has recently resumed his duties, was the subject of the following editorial tribute in the Manchester *Union* recently: "The news of the restoration to health of J. Brodie Smith will be received with sincere rejoicing by the entire Manchester public. He has occupied a position of great responsibility for many years and has met its requirements so successfully that there is not only no serious controversy between a great public service corporation and the public which it serves, but a feeling of hearty co-operation, much of which is due to the unassuming but efficient management by that corporation's immediate representative. But Mr. Smith has been as quietly and unassumingly useful in many other ways. He has given of his time and effort to help forward the things which were destined to be of substantial benefit to the community which he has made his home for so many years, and because he has been so unassumingly but efficiently helpful, there is universal rejoicing at his return to health and to the work which still remains for him to do."

The Bus as an Adjunct.—George Gunther, a real estate dealer at the end of the Highland Park & Lake Burien line of the Seattle (Wash.) Municipal Railway, has made a proposition to the utilities committee of the City Council to provide two motor buses of a type and value to be approved by the board of public works of Seattle, the city to operate the vehicles as a connection between the two municipal railway lines. The buses are to be paid for with bonds bearing 5 per cent interest which are to be a lien on the earnings of the railway lines. Councilman George R. Cooley reported to the committee that property owners in the vicinity of Thirty-fifth Avenue S. W., are planning the operation of a motor-bus line over Thirty-fifth Avenue S. W., Avalon Way, and Spokane Street, into the city, a distance of about 9 miles. They will ask that the Council order the improvement of Thirty-fifth Avenue S. W. by paving 18 ft. in the center of the thoroughfare. At a meeting of the public utilities committee of the Council recently it developed that at least five members favor trying out the auto bus as a solution of the problem of extending and connecting the city's two railway lines. Mayor Gill has not yet taken a definite stand on the bus matter.

Financial and Corporate

RECENT FINANCIAL TENDENCY

Matters of importance in finance have developed more rapidly during the last week than for some time past, but none of the events that have transpired is considered likely to be depressing in its ultimate results, although one or two did tend momentarily to disturb conditions. The cutting of the common stock dividend by the United States Steel Corporation from 1½ per cent to one-half of 1 per cent quarterly was not unexpected, and seems to have been accepted with much grace, particularly as the figures of earnings made public by the company were better than had been expected.

How the process of conserving cash resources through the reduction or deferring of dividends is working is reflected in the total reduction of $7,851,421 so far in dividend payments scheduled for November, 1914, as compared with the same month in 1913. Of this total reduction $5,772,553 is in industrial company payments.

While a number of transportation companies continue to report decreases in traffic, the general situation in regard to the public utilities is considered very favorable. The quarterly report of the Brooklyn Rapid Transit Company, published elsewhere in this issue, and marking a significant change in the policy of this company regarding the publication of its earnings, is particularly interesting in view of present conditions. Other public utility companies, included among them the Pacific Gas & Electric Company, the Byllesby companies and the Cities Service Company, show increases in earnings. The Edison Illuminating Company, Detroit, for instance, reports an increase of 13 per cent in gross over last year and of 16 per cent in September. A gain of 14 to 15 per cent for the year is expected.

As further reflecting the improvement in the bond market in New York it is reported that a considerable volume of trading has taken place recently through the committee of seven which was appointed to pass upon trading in bonds. *Financial America* said in this connection that while some difficulty was reported in the transaction of business, owing to the exactions of the committee, the feeling prevailed that betterment was due and the outlook favorable. Chicago reports a marked improvement in the Western bond market, with prospects for renewed activity in municipal issues. In Boston actual sales of bonds have not been large, but the demand is reported as improving. Such business as exists is largely in tax-exempt municipals, which are now on a basis ranging from 4.05 per cent to 4.20 per cent. The buying continues to come largely from individuals and trustees, institutions being still out of the market.

Only in one direction did the war seem last month to improve trade, and that was in regard to foodstuffs. Exports during September showed an increase of $45,968,000 over the exports for the first month of the war, for which the European demand for food was largely responsible. Everything except foodstuffs, both manufactured goods and crude materials, showed a loss of $61,902,000 in all exports for September of this year, as compared with the same period last year. These figures are obtained from a bulletin issued on Oct. 27 by the bureau of foreign and domestic commerce of the Department of Commerce.

The work of preparing for the inauguration of the federal reserve bank system on Nov. 16 is being rushed. On Oct. 27 the comptroller of the currency gave out detailed statements showing the total amount of reserves that will be released by the national banks in each of the twelve federal reserve districts when the new reserve requirements take effect, based upon the deposits of the banks as shown by the latest report to the comptroller, dated Sept. 12, 1914. The figures show that when the new banks open there will be released in cash and other reserves under the minimum requirement the sum of $464,919,076 to be added to the resources available for transacting business. The more liberal provisions of the new banking and currency law permit the national banks to reduce their reserves and generally enable them to utilize resources that heretofore have been held as security.

BROOKLYN RAPID TRANSIT QUARTERLY REPORTS

The Brooklyn (N. Y.) Rapid Transit Company has adopted the policy of giving out a quarterly report of its earnings, supplementing the official reports which are filed with the Public Service Commission, in accordance with the requirements of that body. The first of these quarterly reports, for the three months ended Sept. 30, 1914, was made public on Oct. 22. Abnormal increases in gross earnings and operating expenses were shown in this report because the operation of the lines of the Coney Island & Brooklyn Railroad is now included in the Brooklyn Rapid Transit System, whereas in the three months of 1913, with which comparison was made, such earnings were not included, inasmuch as the Coney Island & Brooklyn Railroad was not then part of the Brooklyn Rapid Transit System.

Surplus earnings in excess of operating expenses, taxes and fixed charges amounted to $1,920,223 for the three months ended Sept. 30, 1914, a gain of $342,810 over the corresponding period of 1913. Fixed charges, notwithstanding the inclusion of the Coney Island & Brooklyn lines in this quarter's Brooklyn Rapid Transit statement, showed a net decrease of $71,725, as compared with the corresponding period of 1913. Gross operating receipts for the quarter ending Sept. 30, 1914, were $7,239,787, compared with $6,606,299 for the corresponding period of 1913. The abnormal gain indicated by these figures, namely, $633,487, was due to the operation this year, as a part of the system, of the lines of the Coney Island & Brooklyn Railroad. Operating expenses for 1914 were $3,837,865 against $3,430,933 a year ago. This increase of $406,931 is due to the fact that 1914 operations embrace the Coney Island & Brooklyn Railroad. Fixed charges for the same reason would—normally—show an increase, but by reason of the conversion of Brooklyn Rapid Transit Company's refunding 4's an actual net reduction is shown of $71,725. The surplus figures compare as follows: 1914, $1,920,223; 1913, $1,577,413, a gain of $342,810. The figures in statement form follow:

Three Months Ended Sept. 30	1914	1913
Gross operating revenues	$7,239,787	$6,606,299
Expenses	$3,837,865	$3,430,933
Taxes	434,870	468,819
Operating income	$2,967,051	$2,706,546
Non-operating revenue	115,707	105,128
Gross income	$3,082,758	$2,811,674
Income deductions	1,162,535	1,234,260
Net	$1,920,223	$1,577,413

MAINE RAILWAY AND POWER DEAL

The Androscoggin Electric Company filed a copy of its articles of incorporation with the registrar of deeds at Lewiston, Maine, on Oct. 26. The company has an authorized capital stock of $2,000,000, of which $1,500,000 is common stock and $500,000 preferred stock. The officers of the company are Harold S. Libbey, president; Julius Parkhurst and John A. Morrill, directors. The purpose of incorporation is to carry out the deal which has been pending for some time for uniting the interests of the Libbey properties in and about Lewiston with the power development at Rumford under the control of Hugh J. Chisholm, Portland. It is announced that the management of the properties which are to be brought together will be in the hands of Hugh J. Chisholm, ex-Governor Cobb of Maine and Maynard S. Bird, Rockland.

It is stated that before his death Hugh Chisholm had in mind the extension of the high tension transmission lines from Rumford to other parts of the State. His son, Hugh J. Chisholm, has worked along the same lines, and is said to have had a plan long in mind for acquiring large interests in central Maine with an outlet to Portland for the Rumford Falls power as yet unused and undeveloped. The Lewiston & Auburn Electric Light Company, the property of which is included in the transaction, was a consolidation of the Lewiston & Auburn Electric Light Company and the E. W. Gross Electric Light & Power Company, competing companies. Libbey & Dingley, at that time, were in the woolen mill business and were the owners of the Lincoln mill. Mr.

Gross established his power and light plant in this mill. As the business of Libbey & Dingley developed they bought land and flowage rights on the Androscoggin River above Lewiston Falls. Subsequently Stone & Webster, Boston, bought the water-power rights and other privileges of the Union Water Power Company at Deer Rips. This property was later bought by W. S. Libbey, and Libbey & Dingley began to carry out consolidation plans along their own lines. The Portland, Lewiston & Gray Railroad was built under the personal supervision of W. S. Libbey, who died a few weeks prior to the opening of the road in July of this year. The road is 30 miles in length between its terminal points on the Lewiston, Augusta & Waterville Street Railway in Auburn and the Portland Railroad at Deering Junction. There is a surplus of power available at the development of the Rumford Falls Electric Light & Power Company. Some years ago the Chisholms began purchasing a right-of-way from Rumford Falls through to Portland, which was to be used for a pole line which would carry high-tension transmission wires from that point into Portland.

Auburn & Syracuse Electric Railroad, Syracuse, N. Y.—The directors of the Auburn & Syracuse Electric Railroad on Oct. 16 voted to defer the current quarterly dividend on the $1,500,000 of 6 per cent non-cumulative preferred stock on account of the present business conditions. Dividends at the rate of 6 per cent have been paid from the year 1907 to date.

California Street Cable Railroad, San Francisco, Cal.—The California Street Cable Railroad on Oct. 22 filed an application with the Railroad Commission of California requesting authority to issue $384,000 of serial bonds, par $1,000, at a price not less than 90. These bonds will bear 6 per cent interest and will mature in blocks annually, from Jan. 1, 1916, up to and including Jan. 1, 1927. The proceeds are to be used in refunding part of the outstanding bonded indebtedness due Jan. 1, 1915, amounting to $900,000. The difference will be made up from moneys now in the sinking fund.

Cape Breton Electric Company, Ltd., Sydney, N. S.—The Cape Breton Electric Company has an application before the Nova Scotia Utility Commissioners for sanction of a proposed bond issue. The application states that the company does not propose in the meantime to issue the bonds but to give them as collateral for advances. The Commonwealth Bank of Massachusetts and the Canadian Bank of Commerce have, it is stated, advanced $75,000 to the company. In case the company is called upon to pay the advances at once the bonds would be sold now. The last issue of similar bonds was sold at 91 per cent, but it is not likely that this percentage would be realized now.

Central Electric Railway, Kansas City, Mo.—The committee representing the holders of the bonds of the Central Electric Railway deposited under the agreement dated March 10, 1914, has announced that interest due on Nov. 1 will be paid on receipts for deposited bonds at the New York Trust Company and on undeposited bonds at the Equitable Trust Company, both of New York.

Chicago & Oak Park Elevated Railroad, Chicago, Ill.—Samuel Insull, receiver of the Chicago & Oak Park Elevated Railroad, has applied to the United States District Court for authority to issue certificates ranking ahead of the company's bonds to provide for track elevations in Oak Park.

Cincinnati (Ohio) Traction Company.—According to the report made to the city auditor of Cincinnati the gross earnings of the Cincinnati Traction Company for July, August and September were $1,343,554, or about 20 per cent less than for the same period last year. It is said, however, that an improvement has been shown recently.

City Light & Traction Company, Sedalia, Mo.—The City Light & Traction Company, which is controlled by the Doherty interests, is now offering for subscription $25,000 of one-year 6 per cent coupon gold notes, par $100, dated Oct. 1, 1914, interest payable quarterly. The first mortgage bonds of the company are pledged as collateral to secure the issue of notes, in the ratio of $200 par value for every $100 of notes outstanding. The notes are being offered at par and accrued interest.

Cleveland (Ohio) Railway.—The operating report of the Cleveland Railway for September shows that the 1 cent charge for transfers yielded $58,682, but even with this addition to the regular income a net ordinance deficit of $22,947 was shown, including the $18,000 special allowance for the old equipment fund. The actual deficit was $89,452.44. The ordinance deficit still further reduced the interest fund which at the beginning of October was $200,706. The report showed 26,191,761 fares collected, a decrease of 492,216 from the number recorded for September, 1913.

Coney Island & Brooklyn Railroad, Brooklyn, N. Y.—The board of directors of the Coney Island & Brooklyn Railroad has been increased from nine to thirteen by the addition of T. S. Williams, J. H. Bennington, George D. Yeomans and William Seibert, all of the Brooklyn Rapid Transit Company.

Fresno (Cal.) Interurban Railway.—The Railroad Commission of California has issued an order authorizing the Fresno Interurban Railway to issue $12,000 of stock and $24,000 of bonds, being a part of 600 shares of common stock and $120,000 of first mortgage bonds previously passed upon by the commission. This company has 2 miles of line in operation between Fresno and Belmont Avenues in Fresno and Alvina Heights.

Gary, Hobart & Eastern Traction Company, Hobart, Ind.—It is reported that on Oct. 20 the South Side Trust & Savings Bank, Gary, Ind., trustee for the bondholders of the Gary, Hobart & Eastern Traction Company, filed suit in the Circuit Court at Crown Point, asking for the foreclosure of the company's mortgage on account of a default in interest payments. This road was incorporated in Indiana in 1911 with $125,000 of stock to build an electric railway between Gary, Hobart and Valparaiso, and at present nine miles of line between Gary and Hobart are in operation.

Kentucky Traction & Terminal Company, Lexington, Ky.—Chandler Brothers & Company, Philadelphia, recently said in a circular that the actual surplus available for dividends on the preferred stock of the Kentucky Securities Corporation, which owns the Kentucky Traction & Terminal Company, had increased from $94,000 in 1912 to $156,000 in 1914. After the complete rehabilitation in 1911, a stipulated maintenance charge was set aside rising from 12 per cent for 1911 to 16½ per cent for the year 1914-1915. It is stated that expenditures out of earnings have already built up a large equity for the bonds and preferred stock of the two companies, Kentucky Traction & Terminal Company bonds showing a surplus of 80 per cent over fixed charges.

Lehigh Valley Transit Company, Allentown, Pa.—The gross earnings of the Lehigh Valley Transit Company for November, 1913, were $173,648, almost as much as for August, which was the largest month's business in the history of the company. The net earnings were $90,479, an increase of $6,626. According to an authoritative report, the subsidiaries of the company are doing well, particularly the Easton Consolidated Electric Company and the Lehigh Valley Light & Power Company. No large capital expenditures will be necessary for some time to come, for the improvement program undertaken several years ago has been completed. The earnings of the system are not likely to be adversely affected by the prevailing business depression because of the great diversity of industries in the company's territory and the fact that orders on hand are large.

London (Ont.) Street Railway.—At a recent meeting of the shareholders of the London Street Railway authority was given to issue additional bonds of $50,000.

Marion & Suburban Railway, Marion, Ohio.—The hearing of the suit of A. E. McBee, New York, against Newton J. Catrow and other directors of the Marion & Suburban Railway was begun before United States District Judge Hollister at Cincinnati on Oct. 19. Mr. McBee is endeavoring to recover from the directors several thousand dollars alleged to be due on bonds purchased from Webb & Company. He charges that fraud entered into the issue and guarantee of the bonds and that only a small portion of the road was built at a cost of $15,000, the remainder of the proceeds of the $250,000 bond issue being diverted from the treasury of the company.

Northern Electric Railway, Chico, Cal.—At meetings of security holders held in San Francisco on Oct. 13 and 14, committees were chosen for the holders of the Northern Electric Company bonds, the Northern Electric Railway bonds, the Sacramento & Woodland Railway bonds, the Marysville & Colusa Railroad bonds (and the respective notes secured thereby), and also for the unsecured creditors. John S. Drum, one of the Sloss Security Company's trustees, said that the Northern Electric Railway system had cost $12,500,000, of which $3,500,000 was realized from the sale of underlying bonds, $5,500,000 from the flotation of securities and notes and $3,500,000 from advances by the chief stockholders, without including $750,000 of advances by members of the Sloss family not directly interested in the property. The latter two items are held junior to all other claims and liens. It is understood that the securities sold and pledged are as follows: Northern Electric Railway, first mortgage 5's, sold to the public, $952,000, pledged as collateral for notes, $5,700,000; Northern Electric Company, first mortgage 5's, sold, $2,544,000; pledged, $1,206,000; Sacramento & Woodland Railway, first mortgage 5's, sold, $435,000; pledged, $315,000; Marysville & Colusa Railroad, first mortgage 5's, sold, $385,000; pledged, $365,000. Meetings of the committees were adjourned for three weeks. Rudolph Spreckels has issued a statement opposing the reorganization of the Northern Electric system. On Oct. 23 the Railroad Commission of California rendered a decision authorizing notes amounting to $2,116,575 previously issued by the company without the approval of the commission, and also notes amounting to $37,079 issued by the Marysville & Colusa branch and notes amounting to $118,750 of subsidiaries of the Northern Electric Railway. The purpose was to place the creditors holding notes now invalid in the same position as they would have been had their notes been issued with the approval of the commission.

Ogden, Logan & Idaho Railroad, Ogden, Utah.—The Ogden, Logan & Idaho Railroad was formed on Oct. 15 in Utah with $5,000,000 of authorized capital stock as a consolidation of the Ogden (Utah) Rapid Transit Company and the Logan (Utah) Rapid Transit Company. It is stated that two and one-half shares of the new stock will be given in exchange for each share of the Ogden Rapid Transit Company's stock and one and one-quarter shares for each ten shares of the Logan Rapid Transit stock. The articles of incorporation permit the following extensions: 44 miles between Logan and Brigham City, 21 miles between Logan and Preston, Idaho, and 6 miles between Idlewild and Huntsville, thus completing the Ogden & Preston interurban line and the extension on the Ogden Valley line. The officers at incorporation are as follows: President, M. S. Browning; vice-president, L. R. Eccles; second vice-president, Joseph Scowcroft; treasurer, R. B. Porter, and secretary, Royal Eccles. The directors are: D. C. Eccles, A. P. Bigelow, W. H. Wattis, A. T. Wright and H. H. Spencer, of Logan, and Mariner S. Eccles, Joseph Quinney, D. C. Budge, Joseph Howell and H. E. Hatch, of Logan. P. D. Kline is general manager.

Ohio River Electric Railway & Power Company, Pomeroy, Ohio.—The Public Utilities Commission has received an application from the Ohio River Electric Railway & Power Company for permission to issue $300,000 of stock, of which one-half is to be common and the remainder preferred, for the purchase and unification of the lines between Racine and Hobson, passing through Middleport and Pomeroy. The section between Racine and Middleport is owned by a Delaware corporation of the same name, and that between Middleport and Hobson is the property of Richard E. Ellis.

Waukegan, Rockford & Elgin Traction Company, Chicago, Ill.—Judge Jesse Baldwin of the Circuit Court of Chicago on Oct. 19 appointed R. L. Peck receiver of the Waukegan, Rockford & Elgin Traction Company on application of Peter Knowe, a stockholder and owner of outstanding notes. This road is projected from Waukegan via Roselle to Palatine and also to Fox Lake, Elgin, etc., and at last accounts was in operation for fifteen miles from Palatine to Waucomda.

Woodstock & Sycamore Railway, Genoa, Ill.—At a meeting held in Chicago on Oct. 19 stockholders of the Woodstock & Sycamore Traction Company and the Chicago, Waukegan & Fox Lake Railway voted to consolidate the two roads into the Woodstock & Sycamore Railway. Arrangements were made for the issuance of bonds and stock to complete the construction of the road from Genoa north to Marengo, Ill. The main office of the company will be in Genoa, Ill. J. P. Mason, Elgin, was elected president, and P. E. Ryan, St. Charles, was chosen vice-president

DIVIDENDS DECLARED

American Railways, Philadelphia, Pa., quarterly, 1¾ per cent, preferred.

Brazilian Traction, Light & Power Company, Ltd., Toronto, Ont., quarterly, 1½ per cent.

Columbus Railway, Power & Light Company, Columbus, Ohio, quarterly, 1¼ per cent, preferred, series B; quarterly, 1¼ per cent, common.

Cumberland County Power & Light Company, Portland, Maine, quarterly, 1½ per cent, preferred.

Easton Consolidated Electric Company, Allentown, Pa., one third of 1 per cent, monthly.

Grand Rapids (Mich.) Railway, quarterly, 1¼ per cent, preferred.

Lincoln (Neb.) Traction Company, quarterly, 1½ per cent, preferred.

Ohio Traction Company, Cincinnati, Ohio, quarterly, 1¼ per cent, preferred.

Union Street Railway, New Bedford, Mass., quarterly, 2 per cent.

BROOKLYN SAFETY WORK

A Review Is Presented of the Safety Campaign Plan of the Brooklyn Rapid Transit Company for 1914-1915

The public safety campaign in the Brooklyn public schools for the school year, that of 1914-1915, has been begun by the bureau of public safety of the Brooklyn Rapid Transit Company under the renewed patronage of the Brooklyn committee of public safety. The safety lecturers have already started again on their rounds of the public schools and from now until the close of the school year concrete safety teachings will be presented in attractive form to all the school children of the borough. Parochial and other sectarian schools are included in this work.

The campaign for the current school year will include several of the features which proved so attractive during the preceding year and in addition many new features. New lectures have been prepared for the schools by Mrs. Jessica P. McCall, supervisor of the bureau of public safety. In place of the large accident drawings used in the public schools last year, each lecturer has been provided with a stereopticon machine and a large collection of stereopticon slides, consisting for the most part of photographs specially posed to illustrate the common dangers to which children are exposed in a crowded city.

As far as practicable, moving pictures will again be used in the Brooklyn school campaign, the bureau of public safety having worked out an arrangement with the fire department whereby "The Price of Thoughtlessness" and other moving picture films to be employed will be transferred to a non-inflammable substance, thereby making the security against fire hazard greater than ever before. A new moving picture film for use in the Brooklyn safety campaign has been produced and is shortly to be in shape for exhibition. The organization of safety patrols is being continued. Eight new patrols have already been organized, the current news furnishing a constant variety of material for the bulletins which are maintained in connection with the various safety patrols.

In response to a request from Miss M. E. Bacon, principal of Public School 107, a lecturer from the bureau of public safety organized a safety patrol and a careful club from a group of pupils selected by Miss Bacon as representative leaders of safety in her school and school community. On Oct. 2 Mrs. McCall, supervisor of the bureau of public safety, met with Miss Major, director of safety organizations in Public School 125. Miss Major had selected a group of boys and girls for membership in the safety patrol and the careful club and the meeting was called at 3 o'clock. Very able work was done by the safety patrol of this school last year.

The opening lecture in the fall campaign was presented to the pupils of St. Agnes School by Mrs. M. F. Van Riper, now a member of the staff of lecturers of the bureau of public safety. Nine hundred children were reached at this assembly. On Oct. 5, Mrs. McCall gave a talk on safety to the pupils in Public School No. 115. Charles W. Lyons, district superintendent, was present at the assembly, after which he called a fire drill as a part of the safety program. Members of the parents' association were also present. Miss Callahan organized a safety patrol and has requested a bulletin board for the safety reports. In cooperation with the fire department, the lecturers spoke on fire prevention in the public schools on Oct. 9, the day set aside by Fire Commissioner Robert Adamson of New York for the formal observance on that subject.

On Oct. 6, Miss Lillian Shipp gave a talk illustrated with accident drawings to 200 kindergarten children in the Sacred Heart School. On Oct. 7, at the school of St. Mary's Star of the Sea 1300 children were reached. There are police guards among the boys of this school who will be appointed to the duties of the safety patrol.

A broadcast distribution of safety buttons is under way in the public schools. The button for general distribution shows a picture of a woman standing on an isle of safety in a public street with a little child on either side and trolley cars, carriages and automobiles operating about her. An official button adopted by the Brooklyn committee of public safety and having a symbolic female figure, signifying the Goddess of Caution, with a child on either side on a pedestal bearing the injunction "Be Careful" has been provided and will be presented to the members of the safety patrols and other deserving of special recognition by reason of their service to the public safety cause. A new edition of safety calendars is in process of preparation for 1915 and will be provided for all the school classrooms in due time.

A complete report of the activities in the summer schools and playgrounds and a forecast of the work in the public schools for the year 1913-1914 was made to the Brooklyn committee of public safety at its recent annual meeting.

Since the fall campaign opened the bureau of public safety has received requests for safety lectures from several outside cities.

NEW ZONE FARE SCHEDULE SUSPENDED PERMANENTLY

The Public Service Commission of the State of Washington has issued an order permanently vacating and suspending the new zone schedule of passenger rates filed by the receivers of the Seattle, Renton & Southern Railway several months ago, which anticipated the collection of an additional 5-cent fare from all passengers beyond Orcas Street, making a 10-cent fare for every patron beyond that point within the city limits. Early last summer announcement was made that on July 10 the new schedule of rates on the Seattle, Renton & Southern Railway would go into effect, the commission at that time granting the increase asked for by the receivers without protest from any source. The City Council directed the corporation counsel to combat the order, with the result that Assistant Corporation Counsel Ralph S. Pierce spent several months in preparing for the hearing before the commission which was concluded recently and has resulted in the permanent suspension of the proposed increased rate of fares.

Figures presented by the receivers indicated that the property is not paying interest and operation cost on the valuation of $1,601,315 which was fixed by H. L. Gray, formerly chief engineer of the commission.

The commission points out that Mr. Gray started with a figure of $832,527 as the cost of reproducing the line, then arbitrarily added 1 per cent for engineering, legal and general expenses, 7½ per cent for interest during construction and 10 per cent for discounts and commissions. F. S. Burroughs, the present engineer of the commission, by eliminating the arbitrary multiple found a reproduction value of $1,171,227 and a present value of $959,955. In this connection the commission says in part in its decision:

"Shippers and passengers are now paying interest upon millions of dollars that have no existence outside of the imagination or arbitrary notion of a so-called expert. Mismanagement of a utility requiring heavy payments for litigation and legal services is not chargeable to the patrons in increased fares.

"While this commission has been unable to find in any city in the United States outside of Seattle any street railway which charges more than 5 cents for one continuous trip within the city limits, we have found many cities where the charge is less.

"It is the opinion of the commission that if the present company should remove all its property from this right-of-way, either the city of Seattle or private enterprise would rebuild a better road and serve the public at as reasonable if not better rates than we will now by order establish.

"For the foregoing reason it is the conclusion of the commission that the proposed shedule of rates filed with this commission and suspended by our orders are unjust and unreasonable, and that the rates now in force and effect are just, reasonable and sufficient."

Scott Calhoun and Joseph Parkin, receivers of the company, have filed with the clerk of the court a suit in equity against the members of the Public Service Commission and Attorney General W. V. Tanner, asking the United States District Court to set aside the order of the commission refusing to permit the railway to increase its fares and to enjoin the commission from enforcing the provision of its decree. The company claims that the order is confiscatory.

Folding Steps and Doors in Montreal.—The Montreal (Que.) Tramways has decided to equip the rear platform of all its double-truck cars with folding steps and doors.

Service Complaint Hearing Continued.—On request of City Solicitor Walter M. Schoenle, the hearing of the complaint of the city of Cincinnati, Ohio, against the Interurban Railway & Terminal Company has been continued to Nov. 24. A compromise schedule has been worked out by the company officials and Mr. Schoenle, and it is desired to test operation for an experimental period of some days before the case is heard.

Rehearing in Service Case Refused.—The Public Service Commission of the First District of New York has denied the application of the Nassau Electric Railroad and the Brooklyn Heights Railroad for the abrogation or a rehearing of its final order regulating the service on the Vanderbilt Avenue and Sixteenth Avenue lines, which required the operation of an increased number of cars in the morning and evening rush hours.

Ruling in Suburban Fare Case.—The State Public Utilities Commission of Illinois has ruled that while 2 cents a mile is the maximum passenger fare in Illinois, a rate as much cheaper as may be deemed desirable and adequate may be established with the permission of the commission. The ruling was made in the suit of the cities of LaGrange and Brookfield against the Suburban Railroad and the Chicago & West Towns Railway to discontinue a new passenger rate placed in operation on July 1, 1913. The commission directs the companies to return to the old rate until the commission can inquire into its reasonableness. The former rate was less than 2 cents a mile and was raised to 2 cents a mile, the maximum by law.

Hearing on Rush-Hour Fares in Rochester.—The Public Service Commission of the Second District of New York fixed the date for a second hearing on the application by the Mayor of Rochester for an order requiring the New York State Railways, Rochester Lines, to charge only a 3-cent fare in rush hours, for the abandonment of the State Street carhouse for regular storage purposes and for rerouting of certain lines for Saturday morning, Oct. 31. After the first hearing the company on the order of the commission furnished to the city a statement of receipts in rush hours for two months, and also a statement of receipts and expenditures in the company's last fiscal year. These statements of receipts were referred to in a brief item which was published in the ELECTRIC RAILWAY JOURNAL of Oct. 24, page 986.

Use of Front End Defended.—The City Commissioners of Lexington, Ky., heard a number of citizens and representatives of commercial organizations and a committee of the company's trainmen recently in regard to the front door rule adopted by the Kentucky Traction & Terminal Company. No action was taken nor will any be taken until the commission is advised as to its authority in the premises. F. W. Bacon, vice-president of the company, defends the use of the front door as a step in the interest of safety and reduction of hazard. He cites the use of similar plans in Chicago, Philadelphia and other cities and says that since the cars have been operated under the new plan in Lexington there has been a marked reduction in the number of accidents which could be classed as step accidents.

"Safety First" Meeting in Ohio.—At a joint conference of representatives of steam and interurban railroads and the members of the State Utilities Commission to be held in Columbus, Ohio, in January, the State-wide "safety first" movement will be placed in concrete form. A preliminary conference was held in Toledo on Oct. 23 between the managers of the interurban railroads and the State Commission at which some thirty electric railway men reviewed the measures taken by their roads to prevent accidents. The Toledo & Western Railroad reported that not a passenger had been killed in five years. It was the consensus of opinion that automobiles were responsible for most accidents at grade crossings. At the suggestion of G. O. Smith, supervisor of safety for the Toledo Railways & Light Company, a committee was appointed, with F. W. Coen, vice-president and general manager of the Lake Shore Electric Railway, as chairman, to consider the question of organization and to prepare drafts of "safety first" measures thought desirable to be presented to the next General Assembly of the State for passage.

Court Rules on Smoking.—Holding that smoking on street cars, other than on open coaches such as are used on cable lines, is a nuisance, and should be abated, Judge Everett Smith, in the Superior Court of King County, recently entered an order enjoining the Puget Sound Traction, Light & Power Company, Seattle, from further permitting this privilege to passengers, and directed the company to pay John Mills Day $10 damages. Mr. Day complained that he and members of his family have been made ill by the tobacco fumes on Wallingford and Meridian cars, and asked for damages and an injunction. A. L. Kempster, manager of the Seattle division of the company, testified that he would obey an order if issued by the court. Judge Smith said: "In the present instance as well as in all other conditions of complex modern civilization, the individual must yield his preferences and indulgences to the welfare and advancement of society at large. Personal liberty is not licensed to offend." The company is required to remove its notices permitting smoking from all cars except those having seats facing an open exterior such as cable cars.

Electric Railway Freight Service Urged for Washington.—Establishment of electric railway freight service for bringing food into Washington from points in Virginia and Maryland, and a news agency whereby the public may be kept accurately informed as to the state of the market are suggestions advanced in the annual report of John H. Sherman, superintendent of weights, measures and markets of the District of Columbia for improving cost of living conditions in the capital. The recommendation for the electric railway freight service carries with it a proposed plan for the conversion of the Georgetown market into a receiving station for produce brought in from Virginia. Mr. Sherman says: "One of the most important steps which must be taken if we are to make full use of the resources of the surrounding territory to feed the city cheaply is the establishment, within the city, of electric railway freight service between midnight and 4 a.m. and for two or three hours at some other part of the day, when traffic is now lightest. Such service should extend on all lines of the city and should provide for running loaded cars directly from the country section to their destination in the city without rehandling the load. Our local produce markets are now supplied, in the main, by wagons from a radius of about 20 miles. With electric railway freight service and switches to both municipal and private markets we can supply the markets by electric railway from a radius, in some directions, of 50 miles, with greatly increased supply of goods, at lower cost."

Traffic in Toronto.—A hearing was held before the Ontario Railway Board in Toronto on Oct. 21 regarding the service of the Toronto Railway. The company contended that the closing down of factories and the reduction in the forces of mercantile establishments had reduced traffic and automatically relieved such traffic congestion as had previously existed. The gross earnings for August decreased $30,000, as compared with the same month in 1913, while the gross earnings for September, 1914, decreased $50,000, as compared with September, 1913. Up to the time of the hearing on Oct. 21 gross earnings for the month had increased over the same period of last year on only three days. During the year 201 new cars had been added to the system. The daily schedule was 699 cars between rush hours and 836 cars during the periods of heavy traffic. C. R. Barnes, electric railway inspector of the Public Service Commission of the Second District of New York, who, at the request of the Ontario Railway Board, reported recently on traffic in Toronto, said on Oct. 21 that his recommendation favoring more cars and extensions was not intended to cover a situation such as had developed following the outbreak of the war. He thought the present time was hardly favorable for the spending of any considerable amount of money to be charged to capital account. Chairman McIntyre, of the Railway Board, agreed with Mr. Barnes that conditions had altered. He is said to have expressed the opinion, however, that the money stringency should not prevent the company from carrying out plans for re-routing and perfecting other work which would tend to improve accommodations and service.

Personal Mention

Mr. W. B. Nantel, formerly Minister of Inland Revenue in the Canadian government, has been appointed to the Dominion Railway Commission, succeeding Mr. N. E. Bernier.

Mr. J. P. H. de Windt, vice-president and general manager of the Birmingham Railway, Light & Power Company, Birmingham, Ala., has been elected president of the Alabama Light & Traction Association.

Mr. F. W. Hoover, vice-president and general manager of the Nashville Railway & Light Company, Nashville, Tenn., and also vice-president of the Tennessee Power Company, has been elected president of the Nashville-Gallatin Interurban Railway to succeed Mr. H. H. Mayberry, who is now chairman of the board.

Gen. George H. Harries, president of the Louisville Gas & Electric Company, Louisville, Ky., has been elected president of the Omaha Electric Light & Power Company, Omaha, Neb. General Harries will devote part of his time to the Omaha property, although maintaining his home at Louisville, where he will continue in charge of the local gas and electric properties for H. M. Byllesby & Company.

Mr. C. W. Kellogg has been appointed manager of the Mississippi River Power Company, Keokuk, Ia., to succeed Mr. J. A. Trawick, who resigned recently. Mr. Kellogg was graduated from the Massachusetts Institute of Technology. Since 1905 he has been representing the Stone & Webster interests in Texas, being manager of the El Paso Electric Railway and the Stone & Webster light and railway properties at Port Arthur and Beaumont.

Mr. W. H. McGrath, who has been assistant to Mr. A. W. Leonard, vice-president and general manager of the Puget Sound Traction, Light & Power Company, has been appointed manager of the company, with headquarters at Seattle. Mr. McGrath was born in Massachusetts and has been identified with Stone & Webster since 1901. He entered the employ of the firm at the home office in Boston following his graduation from Harvard University.

Mr. George S. Rice has been appointed by the Public Service Commission of the First District of New York division engineer for the sixth division, which includes the new tunnels to be constructed under the East River and the Fourth Avenue subway in Brooklyn. Mr. Rice succeeds Mr. Frederick Noble, who recently resigned to take up private practice. Mr. Rice was formerly the chief engineer of the commission, but has been out of its service for some years.

Mr. J. A. Rosenberger has been appointed superintendent of the Owosso and Corrunna division of the Michigan United Traction Company's lines to succeed Mr. R. A. Barnett, resigned. Mr. Rosenberger was connected with the Indianapolis & Eastern Railway from 1903 until 1905, when this property became a part of the Terre Haute, Indianapolis & Eastern Traction Company. At the time of this consolidation he was made cashier of the company and later was appointed assistant auditor. In 1912 he resigned from the Terre Haute, Indianapolis & Eastern Traction Company to become chief clerk to the chief engineer of the Michigan United Traction Company, in which position he has continued up to the present time.

Mr. W. W. Freeman, who has been elected president of the Union Light, Heat & Power Company, Cincinnati, and the South Covington & Cincinnati Street Railway Company, subsidiaries of the Columbia Gas & Electric Company, vice Mr. James E. Ernst, resigned, was previously connected with the Alabama Power Company at Birmingham, Ala., and prior to that was for many years vice-president and general manager of the Edison Electric Illuminating Company, Brooklyn. He is a past-president of the National Electric Light Association and of the Association of Edison Illuminating Companies. Mr. Freeman was born in Exeter, Ont., on June 8, 1872, and took up work in the lighting industry as a stenographer with the Brooklyn (N. Y.) Edison Company, advancing step by step to be vice-president and general manager.

Mr. Frederick S. Pratt of Stone & Webster was elected chairman of the board of directors of the Puget Sound Traction, Light & Power Company, Seattle, Wash. Mr. Pratt is forty-two years of age. He was graduated from Harvard and has been identified with the Stone & Webster interests for nearly twenty years. His first position was in the engineering department in the Boston offices. Soon after the Seattle fire in 1889, when the late Jacob Furth began the work of reorganizing and reconstructing the various electric railways in Seattle under one management, Mr. Pratt took the active management of the properties for a year subsequently, returning to Boston. During his identification with Stone & Webster Mr. Pratt's work has been largely with the company's interests on Puget Sound, although his headquarters have been in the East. He will remain in Boston. Mr. Pratt was formerly vice-president of the Puget Sound Traction, Light & Power Company.

Mr. A. W. Leonard, for the last two years vice-president and general manager of the Puget Sound Traction, Light & Power Company, with headquarters in Seattle, Wash., was on Oct. 24 elected president of the company and member of the board of directors to succeed Jacob Furth, deceased. Mr. Leonard was born in Monmouth, Maine, forty-one years ago. Nineteen years ago he entered the employ of Stone & Webster as bookkeeper for the Edison Electric Illuminating Company, and was promoted to general manager and superintendent of the company twelve years ago. He was transferred to Houghton, Mich., as superintendent of the Houghton County Electric Light Company, and was subsequently manager of that property and the Houghton County Traction Company for four years. He then went to Minneapolis as manager of the Minneapolis General Electric Company. In this position he had practical supervision over all the Stone & Webster properties and plants in the Middle West. On Oct. 12, 1912, he was appointed vice-president and general manager of the various Puget Sound companies.

Mr. Victor T. Noonan, secretary of the general safety committee of the Rochester Railway & Light Company, Rochester, N. Y., has been appointed director of industrial and public safety for the State of Ohio. The position is a newly created one, and is directly under the Governor. Mr. Noonan, who is a former Rochester newspaper man, was appointed editor of the *Gas and Electric News* when that publication was started by the Rochester Railway & Light Company in 1911. In 1912 Mr. Noonan was appointed secretary of the general safety committee of the company. In the two years that he has been secretary of the committee the safety work of the company has become known throughout the country. He is said to have been the first safety man in the electric industry to prepare lantern slides showing right and wrong ways of working, and the first in the same industry to prepare a motion picture play along the same lines. This was "The Lineman." In September, 1913, Mr. Noonan organized the Employees' Benevolent Association of the company with a membership of forty men. At present this association includes practically all the company's employees. Mr. Noonan is a member of the safety committees of the Empire State Gas & Electric Association, the National Electric Light Association and the National Industrial Safety Council, and is also a member of the Lecture Bureau of the National Association of Manufacturers.

OBITUARY

John Campbell, superintendent of transportation of the Connecticut Company at Bridgeport, Conn., is dead. Mr. Campbell was born in Scotland. He was employed by the Bridgeport Traction Company and its successors for twenty-two years.

Jay Newal Ward, formerly secretary of the Central City Railway, Peoria, Ill., died recently at his home in Los Angeles. For many years Mr. Ward was one of the active business men of Peoria identified with street railway, banking and manufacturing industries.

George Matthews Morrison, motor instructor of the subway division of the Interborough Rapid Transit Company, New York, died on Oct. 14 after a brief illness. Mr. Morrison entered the service of the company thirty-two years ago. He was engine foreman, and for some time was employed in the engine shops at Ninety-eighth Street and Third avenue. When the subway opened ten years ago he was appointed instructor of motormen of that division. He is survived by his widow and his mother.

Construction News

An asterisk (*) indicates a project not previously reported.

RECENT INCORPORATIONS

***Quincy & Hamilton Electric Railway, Quincy, Ill.**—Incorporated in Illinois to build an electric railway from Quincy to Hamilton. Capital stock, $525,000. Incorporators: Charles H. Petsch, Philip G. Petsch, William W. Hodgman, James E. Sturms and Olaf Seagust.

***Androscoggin Electric Company, Lewiston, Maine.**—Application for a charter has been made by this company in Maine. In the incorporation of this enterprise, the interests of the Libbey properties of Lewiston are united with the power development at Rumford under control of Hugh J. Chisholm of Portland. Electric railway and power development will be undertaken by the new firm. Capital stock, authorized, $2,000,000. Common stock, $1,500,000. Preferred stock, $500,000. Officers: Harold S. Libby, president; Julius E. Parkhurst, treasurer; directors, H. M. Dingley, Harold S. Libby, John A. Morrill and others.

***Ogden & Idaho Railway, Ogden, Utah.**—Application for a charter has been made by this company in Utah as a consolidation of the lines of the Ogden Rapid Transit Company and the Logan Rapid Transit Company and to build 71 miles of electric lines extending to form links and extensions of the consolidated Ogden, Brigham and Logan systems. The lines to be constructed include 44 miles for the connections between Brigham and provide 21 miles between Smithfield and Preston, Idaho, and 6 miles between Idlewild and Huntsville. Capital stock, $5,000,000. Officers: M. S. Browning, president; L. R. Eccles and Joseph Scowcroft, vice-presidents; R. B. Porter, treasurer, and Royal Eccles, secretary.

FRANCHISES

***Bisbee, Ariz.**—W. E. Bradley has asked the Board of Supervisors for a franchise to build an electric railway from Bisbee to Naco.

Fresno, Cal.—The Fresno Traction Company has received a franchise from the Council to double-track its lines over certain streets in Fresno.

Los Angeles, Cal.—The Board of Public Utilities has recommended to the City Council that Louis Ginger be granted a franchise to construct an incline railway in Griffith Park, Los Angeles. The board suggests that the type of design be placed under the control and supervision of the Park Commission, to whom Colonel Ginger applied for the original franchise about a year ago.

Los Angeles, Cal.—The Public Utilities Committee of the Council has recommended to the Council the request of the residents in the Malibar Improvement district for a franchise for an extension of the East First Street line to the east city limits of Los Angeles. [E. R. J., Sept. 19, '14.]

West Hartford, Conn.—The Connecticut Company has asked the Public Utilities Commission for approval of its proposed method of construction of a second line of tracks on Farmington Avenue in West Hartford, from the end of the present double track westward to a point west of the armory of Troop B, Cavalry, C. N. G. The petition of the company for approval of the reconstruction of tracks on Brooklawn Avenue in Bridgeport has been granted.

Wilmington, Del.—The Wilmington City Railway has received an extension of time until May 1, 1915, in which to lay its tracks in the Ninth Ward in Wilmington.

Brockton, Mass.—The Bay State Street Railway has asked the Council for a franchise to relocate its tracks on South Street and on Pleasant Street in Brockton.

Franklin, Mass.—The Milford, Attleboro & Woonsocket Street Railway has received a franchise from the Council for the relocation of its tracks on West Central Street in Franklin.

Lowell, Mass.—The Bay State Street Railway has asked the Council for a franchise for the relocation of its tracks on First Street from a point on Llewellyn Street to the carhouses in Lowell.

New Bedford, Mass.—The Union Street Railway has asked the Council for a franchise for extensions and relocations of its tracks in New Bedford.

Pittsfield, Mass.—The Berkshire Street Railway has asked the Council for an extension of time on its franchise in which to double-track and build the addition to its line in North Street and Wahconah Street in Pittsfield.

St. Peter, Minn.—The Electric Short Line Railway has received a forty-nine-year franchise from the Council to build an electric line in Pekin.

St. Louis, Mo.—The Southern Traction Company's fifty-year franchise for a downtown loop at the St. Louis approach of the municipal bridge across the Mississippi River, was repealed by the House of Delegates recently. The Council already has taken similar action and the Mayor has promised to sign the bill.

Brantford, Ont.—The Brantford Street Railway has asked the Council for a franchise to extend its lines and construct a loop in Brantford. Work has been begun on the reconstruction of the east-end section of this company's lines in Brantford.

London, Ont.—The London Street Railway has asked the Council for an extension of time on its franchise in which to complete its line on Wharncliffe Road in London.

Snohomish, Wash.—The Everett Railway, Light & Water Company has received a fifty-year franchise from the Council to extend its line from a connection with the Northern Pacific Railroad to the intersection of Union Avenue and First Street in Snohomish. It is said that work on this line will be begun at once.

TRACK AND ROADWAY

Lacombe & Blindman Valley Electric Railway, Lacombe, Alta.—After the completion of the fencing, work on this electric railway will stop for this year. About 31 miles of grading have been completed and culverts placed; 26,000 ties are required. Farncombe & Inkster, Edmonton, are the engineers. D. S. Hogan, Edmonton, general contractor.

Fresno (Cal.) Interurban Railway.—About 750 tons of rails are now en route to Fresno, and work on the second unit of this company's line from Fresno Avenue to the Normal school will be begun by Nov. 1.

Pacific Electric Railway, Los Angeles, Cal.—This company has placed in operation its new Magnolia Avenue line between Sixth Street, Main Street and Harrison Avenue in Arlington. On Oct. 16 this company filed with the State Railroad Commission application for authority to build tracks at grade across certain public highways in Riverside County. This is the initial step in the construction of the proposed 8-mile line from Harrison Street, Riverside, to Corona. It is stated that $25,000 is being spent on the North Pomona cut-off which will enable through cars on the Los Angeles-San Bernardino line to have about twenty minutes. Work on the cut-off is being carried out by company forces.

California Terminal Railway, Sacramento, Cal.—Right-of-way is being obtained by this company through Jamison Canyon. The company plans to build an interurban railway from San Rafael to Sacramento through Marin, Sonoma, Napa, Solano, Yolo and Sacramento Counties. C. W. Conlisk, San Francisco, is interested. [E. R. J., Oct. 17, '14.]

Connecticut Company, New Haven, Conn.—This company is asked to consider plans for the extension of the Dixwell Avenue line from its present terminus, 2 miles beyond the city limits, over the railroad bridge and around the loop to the Centerville town hall, making a belt line with the Whitney Avenue line in Hamden.

Jacksonville (Fla.) Traction Company.—Plans are being considered by this company to extend its lines on Albert Street and Spearing Street in Jacksonville.

Miami (Fla.) Traction Company.—It was recently decided by the directors of this company to continue its line in Miami, out Twelfth Street to Avenue U, instead of stopping at Avenue S as was originally intended, and from there up Avenue U to Fifth Street. B. B. Tatum, Miami, president. [E. R. J., Sept. 19, '14.]

Charlotte (N. C.) Electric Railway.—The Myers Park line extension, a distance of 1 mile, has been placed in operation in Charlotte.

***Algiers, La.**—Local capital is interested in the construction of an electric railway on the lower coast of Algiers. Meyer Eiseman, Algiers, is interested.

Cumberland & Westernport Electric Railway, Cumberland, Md.—The Public Service Commission is considering the petition asking for the proposed belt line extension of this company's line from the Gladstone Hotel, its present terminus in Cumberland, to Washington, connecting with the Lonaconing line, a distance of 2 miles.

East St. Louis & Suburban Railway, East St. Louis, Mo.—This company is asked to consider plans to extend its lines to Mascoutah, 7 miles east of Belleville, as one of the provisions of the granting of a new twenty-year franchise.

Monmouth County Electric Company, Red Bank, N. J.—Plans are being made by this company to improve the condition of its tracks on Union Avenue, Liberty Street and Washington Street in Long Branch.

Kansas City, Mo.—Negotiations are under way as to arrangements for street car traffic across the Kaw River between Kansas City and Bonner Springs while the Central Avenue viaduct is being reconstructed. The plans for the viaduct work are not yet complete, and when they are decided upon the question of traffic will be definitely determined. The viaduct is a part of the elevated system of tracks through the "West Bottoms," and surface travel would take longer for the cars that now use the elevated. The Metropolitan Street Railway and other lines using the viaduct may operate over it while it is being reconstructed, or arrangements may be made for using the Intercity viaduct.

United Railways, St. Louis, Mo.—This company is asked to consider plans to extend its Fourth Street line to Carondelet Park in St. Louis and to extend the Lee Avenue line northwest to bisect the district between the city limits, Union Boulevard, Florissant Avenue and Easton Avenue in St. Louis.

St. Paul (Minn.) City Railway.—This company is asked to build a line on St. Clair Street from West Seventh Street to Oxford Street in St. Paul.

***Long Branch, N. J.**—The city of Long Branch will cooperate with the Freehold Merchants' Association to build an electric line between Trenton and the seashore by way of the county seat. The Long Branch committee favors a terminal in Long Branch. Already considerable work has been done by the Freehold business men to obtain a right-of-way to the shore. The distance between Long Branch and Freehold is 16 miles.

Fallon (Nev.) Electric Railway.—This company has awarded a contract to the Berney Construction Company for the completion of the grade of this railway from a point on the east line of Phillips & Gibbs ranch, working on to Sand Springs, a distance of 16 miles. It is expected that the grade will be completed in a couple of months, and as soon as it is done plans will be made for the sale of the bonds, which have already been arranged for as soon as the work of grading is finished.

Long Island City, N. Y.—The contract for the concrete piles in the foundation for the new elevated structure in connection with the subway extension in Long Island City has been awarded to the Raymond Concrete Pile Company, 140 Cedar Street, New York. Snare & Triest Company, Woolworth Building, New York, are the general contractors.

Cincinnati (Ohio) Traction Company—The route for the proposed belt line in Cincinnati is being planned by this company.

Brantford (Ont.) Street Railway.—Extensive work is to be carried on by this railway this fall. Among the prospects for this year are the rebuilding of the eastward loop and the construction of a loop to connect the railway ending at Palmerston Avenue with the Brant Avenue line, by way of St. Paul's Avenue.

Ottawa & St. Lawrence Electric Railway, Toronto, Ont.—Grading for this railway has been begun. The main line will be 119 miles in length, extending from Ottawa via Morrisburg to River Beaudette on the Quebec border, with a branch line from Metcalfe to Russell. Contracts for grading have been let at various points. [E. R. J., March 28, '14.]

San Antonio (Tex.) Traction Company.—This company is extending and relaying sections of its lines in San Antonio.

Utah Light & Traction Company, Salt Lake City, Utah.—Material is on the ground for the extension of the Holliday line of this company to the mouth of Cottonwood Canyon. Construction is to be begun at once in order that cars may be in operation for the summer business next year. Five miles of new track will be laid from the present terminus to the company's Granite power station at the entrance to the canyon. The extension will follow the county road to Knutsen's Park, then over a private right-of-way to Big Cottonwood Creek and along Big Cottonwood Creek on its south bank on property owned by the company to the terminal near the power station.

Charlottesville (Va.) Interurban Railway.—As soon as financial backing can be secured this company will build its 15-mile line between Charlottesville and Alberne via Albermarle County. Power will be purchased. Walter Washabaugh, Charlottesville, chief engineer. [E. R. J., Aug. 16, '14.]

***Spokane, Wash.**—An independant corporation to build a gasoline railway, to connect with one or both of the Spokane electric systems and extending to Whitworth College and the Country Club was recommended at a recent meeting of the building committee of the Whitworth College Board of Trustees. It is reported that one of the railways companies had offered to operate such a line if it should be built.

SHOPS AND BUILDINGS

Pacific Electric Railway, Los Angeles, Cal.—Three new passenger stations will be built at once by this company at points on its new San Bernardino line. The stations are to be erected at Etiwanda, Alta Loma and Rialto. The contract for their construction has been awarded to the King Company, Los Angeles. Each station will be 30 ft. x 120 ft., single story and of reinforced concrete and hollow tile construction. The three depots will cost in the aggregate about $20,000.

San Francisco-Oakland Terminal Railways, Oakland, Cal.—The new three-story building of this company at Twenty-second Street and Grove Street in Oakland has been completed and the company will move all its departments there at once. The new structure will devote the two upper stories to the executive and operation departments, while the lower floor will be used for a waiting room and for the electrical supply department.

Ogden (Utah) Rapid Transit Company.—Work has been begun by this company wrecking the building on the ground at Twenty-fourth Street in Ogden on which it plans to build its new interurban depot. The structure will be 50 ft. x 20 ft. The contract to build this depot will be awarded in the near future.

POWER HOUSES AND SUBSTATIONS

Corning & Painted Post Street Railway, Corning, N. Y.—This company's cars are now being operated over the entire line by power furnished from the Big Flats power station of the Elmira, Corning & Waverly Railroad and henceforth power is to be regularly supplied to the local line from that source. The operation of the power house of the Corning & Painted Post Street Railway on the North Side in Corning will be discontinued.

Ithaca (N. Y.) Traction Corporation.—Ford, Bacon & Davis, New York, engineers, are building an addition to the power house of this company, in which they are installing one 750-kw bleeder type General Electric turbo-generator with Worthington condenser and auxiliaries. Two 400-hp Edgemoor boilers are now being installed in a new boiler house.

London & Port Stanley Railway, London, Ont.—Bids are being asked by this company for two motor-generator sets to be used in connection with the electrification of this railway.

Manufactures and Supplies

ROLLING STOCK

Hocking-Sunday Creek Traction Company, Nelsonville, Ohio, expects to purchase three cars within the next week.

Danville (Ill.) Street Railway & Light Company will put in service four more prepayment cars on the Roselawn-Oaklawn line.

Sandpoint & Interurban Railway, Sandpoint, Idaho, expects to purchase within the next few weeks trucks with quadruple motors and snowplow equipment.

Boston (Mass.) Elevated Railway is building two new snow plows for the winter season. They will be equipped with Westinghouse No. 306 quadruple motors and type HL unit switch control.

Geary Street Municipal Railway, San Francisco, Cal., has ordered a total of only 125 cars during 1914, and has not ordered fifty more cars, as recently reported.

Pacific Electric Railway, Los Angeles, Cal., is contemplating the purchase of twenty-four all-steel cars through its controlling company, the Southern Pacific Railroad, New York, N. Y.

Richmond Light & Railroad Company, New York, has specified the following details for the thirty-two closed passenger cars recently ordered from the Osgood-Bradley Car Company:

Seating capacity	46	Cables	West.
Bolster centers, length,	17 ft. 2½ in.	Control	K 35
Length of body	28 ft.	Curtain material	Pantasote
Length of vestibule,	41 ft. 4 in.	Designation signs	Hunter
Width of sills	8 ft. 3 in.	Fenders	H. B.
Width over all	8 ft. 4⅛ in.	Gears and pinions	West.
Body	metal	Handbrakes	Lord
Interior trim	ash	Heaters	Consol.
Headlining	Agasote	Headlights	Golden Glow
Roof	arch	Motors	4 West. 323, outside hung
Underframe	metal	Seats	H. & K. No. 300
Air brakes	National A 6	Seating material	rattan
Axles	Standard	Trolley catchers	Earle
Bumpers	Hedley	Trolley base,	West. (Union)

TRADE NOTES

Taylor-Wharton Company, Easton, Pa., expects to complete the construction of its new buildings early next year.

Dallas Equipment Company, Portland, Maine, has been organized to manufacture, build, purchase, sell and deal in street railway cars and other cars and vehicles. The authorized capital stock is $200,000. John H. Pierce, of Portland, is president; William E. Tucker, Chelsea, Mass., treasurer.

Consolidated Car Fender Company, Providence, R. I., has received an order through Wendell & MacDuffie Company, New York, to equip all the cars of the Hattiesburg (Miss.) Traction Company with H. B. lifeguards as a result of a recent successful demonstration conducted with a dummy on this line.

Swedish Ljungström Steam Turbine Company, Ltd., Finspong, Sweden, is constructing at its works a 10,000-hp turbo-generator for the Willesden Power Station in London, England, which was ordered after a 1500-hp unit had been thoroughly tested in the same station, since the beginning of 1913, since which time the turbine has been in daily use.

G. J. Slibeck, formerly sales representative with the Buda Company, has resigned to become sales representative of the St. Louis Steel Foundry Company, and will handle solid manganese steel track work exclusively. This company's solid manganese steel track work business has increased so that it became necessary to appoint a special representative.

Hess-Bright Manufacturing Company, Philadelphia, announces that notwithstanding the European war and the temporary suspension of shipments to the company from Germany, it is now receiving large quantities of DWF bearings from Berlin, more than 125,000 of assorted sizes having come through since Sept. 1. This shipment in connection with the company's large stock on hand when war was declared, together with the increase of its own Philadelphia facilities for manufacture, place the company in an exceptionally good position to minimize any inconvenience which the war might otherwise have inflicted upon users of ball bearings.

Westinghouse Air Brake Company, Wilmerding, Pa., at a meeting of its board of directors elected Henry Herman Westinghouse president to succeed his brother, the late George Westinghouse, founder of this company and numerous other Westinghouse industries. Mr. Westinghouse was born at Central Bridge, Schoharie County, N. Y., in 1853. He attended the schools of Schenectady, and later entered Sibley College of Engineering at Cornell University. Like his brother, Mr. Westinghouse inherited from his father a fondness for mechanics and invention. He invented the well-known high-speed, single-acting Westinghouse steam engine, for the manufacture of which the Westinghouse Machine Company was organized in 1880. In 1873 George Westinghouse invited his younger brother to Pittsburgh to assist him in the management of the air brake company, with which organization he has been connected ever since, for many years past being its first vice-president. He has also been prominently identified with several other of the Westinghouse industries. He was also the organizer and for a number of years the guiding spirit in the management of the Westinghouse Church Kerr Company.

ADVERTISING LITERATURE

Dielectric Manufacturing Company, St. Louis, Mo., has issued "Bullet" No. 2, which describes its graphon paint for metal protection.

Hunter Illuminated Car Sign Company, Flushing, N. Y., has issued a folder which contains a list of large orders for signs received during 1914.

American Electric Works, Phillipsdale, R. I., has issued a price list for Oct. 15, of its wire and cable material, also a price list of its Enduro spark coils.

Ohmer Fare Register Company, Dayton, Ohio, has issued a folder which contains a large list of the companies from which it has received new and renewed contracts during the past several months.

Steel City Electric Company, Pittsburgh, has issued Bulletins Nos. 22, 23 and 24 describing its universal insulator supports and Fullman adjustable and non-adjustable floor outlets, respectively.

Robert W. Adams, Providence, R. I., electrical engineer, has issued a bulletin describing the new engineer's addition of his transmission line calculator, a practical device for the accurate calculation of electrical circuits.

Walter B. Snow, Boston, publicity engineer, has issued an illustrated folder which shows the large variety of technical subjects which have been treated in advertisements, articles, booklets and treatises by members of this company's staff for its clients.

Joseph Dixon Crucible Company, Jersey City, N. J., has issued a folder which contains a report presented at the annual meeting of the American Society for Testing Materials held in Atlantic City in July, 1914, on the results of steel-fence paint tests.

Sterling Varnish Company, Pittsburgh, Pa., has issued an unusually comprehensive and useful catalog on the subject of insulating varnishes and compounds. The catalog contains descriptions of the various types of insulating varnish manufactured by this company and also describes methods of testing insulating varnishes when considering the adoption of any particular varnish. The catalog concludes with general directions for using insulating varnishes.

General Electric Company, Schenectady, N. Y., has issued Bulletin No. 46390 describing its Type CB-5 test meter for use on 100 to 120 and 200 to 240 volt circuits. The construction of the meter is described in detail and the bulletin contains diagrams of connections. This meter combines in one standard several capacities covering a range from light load to full load and making possible rapid testing since no time is lost in changing standards. Bulletin No. 42800 contains a reprint of an article appearing in the *General Electric Review* and devoted to the use of electrically driven air compressors in foundries.

Electric Railway Journal

Consolidation of Street Railway Journal and Electric Railway Review

Vol. XLIV NEW YORK, SATURDAY, NOVEMBER 7, 1914 No. 19

HIGHER VOLTAGE DIRECT CURRENT

The abstract of the Institute paper on the Butte, Anaconda & Pacific electrification which appears elsewhere in this issue is a most encouraging statement for electrical operation, the reported profit of 20 per cent on the initial cost that was effected through savings over the cost of steam operation being enough to deserve the attention of any railroad management. The statements regarding the negligible effects experienced in service with flash-overs at the high potential of 2400 volts are especially interesting, because this has been a point subject to considerable discussion in the past. In view of the satisfactory results obtained from this step another material increase in d.c. voltage may be expected in the near future. Of course, the proposed installation on the Chicago, Milwaukee & Puget Sound Railroad with 3000 volts constitutes an actual step ahead, but so much has been heard of the practical possibilities and experimental installations of d.c. equipment at voltages far in excess of this that it seems not unreasonable to expect, in the near future, some d.c. installations at 5000 volts or even more, especially in situations where the motor is not restricted in size. This prospect, together with that of the practically accomplished development of the mercury-arc rectifier for railway service, constitute possibilities in the art of electrification of steam railroads that were almost undreamed of when it first began on a large scale ten years ago.

ENCOURAGING RATE DECISION

Elsewhere in this issue is printed an extended abstract of one of the most important rate decisions that have lately been handed down on the subject of electric railway fares. In granting a substantial increase in rates to the Middlesex & Boston Street Railway, the Massachusetts Public Service Commission has done far more than to approve measures of financial relief to a deserving company. It has enunciated most significantly its belief that the future of private ownership under public regulation depends upon a living wage to capital no less than to labor. Its unequivocal stand upon this question, as well as the clarity of its findings, the soundness of its methods in dealing with the evidence before it and its constant alertness in drawing conclusions of general application from the material assembled, will interest the student of rate-making from start to finish. The Middlesex & Boston Street Railway, operating many miles of thinly-populated country lines in addition to suburban lines in Newton & Waltham, has been struggling to earn a bare 4.35 per cent on its investment, unable adequately to care for depreciation but forced to pay relatively high rates for borrowed money, to satisfy the public's demands on high-class service and to meet rising costs of material and an arbitrated wage increase. On account of these conditions the company asked for a 6-cent fare on the entire system and an additional charge of 1 cent per transfer, which would add $110,000 to the company's annual revenues. The commission approved only the former request, with the provision that the company sell nine tickets for 50 cents on those portions of its system where a 5-cent fare now prevails, and give free transfers at all existing transfer points. The granted increase is estimated by the board to yield the company about $70,000 per year. This, the commission says, should enable the company to maintain its property in safe condition by expending for maintenance and revenues, until some general basis for dealing with depreciation is ordered or indicated by the board, substantially 20 per cent of its gross revenue, and also to provide very moderate dividends.

IMPORTANT QUESTIONS DECIDED

This Middlesex and Boston opinion discusses a number of important questions which may only briefly be indicated here. The right of the commission to deal broadly with the company's fare problem, regardless of prior franchise agreements concerning fares on its constituent lines, is admirably set forth. In the light of previous court decisions this was not unexpected, but it is wholesome for the powers of the board thus to be brought prominently and clearly before the public. The reckoning of the return upon the basis of capital investment instead of upon reproduction cost is also significant. The commission does not concede for a moment that money lost during the earlier stages of a public service enterprise soundly and honestly managed should be irretrievably gone from the stockholders. In its opinion, public utilities are never finished, and unless they are kept on good trading terms with the public the whole experiment of private ownership under public regulation must fail. Then, too, the commission feels that the more prosperous lines should, to a large extent, pay the losses on the less patronized routes. It is not unreasonable, it is said, to suppose that some advance over the original fares might now be necessary even upon the better-paying lines if these had continued to be separately operated. These various changes and others allowed by the commission are anticipated to produce the minimum hardship upon the communities served, and their working out will be of considerable interest. Welcome as would have been a complete granting of the company's petition, the foregoing points sufficiently show the desire of the commission to protect electric railway investors, and it is a splendid thing for the whole policy of private ownership under public regulation to have a state commission standing as high as that of Massachusetts take such an unmistakable stand. Unless all signs fail, too, the public will cheerfully meet the situation in this fuller recognition of the rights of the electric railway investor. As the opinion of the commission will have a wide circulation, it should be a help to managers of properties far and wide who may be confronted with the question of giving service for less than cost.

ELECTRIC RAILWAYS IN AND ABOUT MANILA

A remarkable illustration of efficient service performed by an Oriental street railway system in the face of a number of singular operating problems is shown by the account of electric railway operation in Manila, published elsewhere in this issue. The success of this pioneer traffic system which has enabled it to give good service can be attributed largely to the development of the Philippine Islands under the American administration.

The street railway and lighting property in Manila, which received its franchise in 1903, two years after the inception of the American regime, has developed with the city. The replacement of lax Spanish educational methods by a modern system or elementary schools, the improvement of the harbor of Manila and the establishment of bureaus of forestry, health, agriculture and constabulary, all contributed to the furtherance of more peaceful civil relations and to the enlargement of the Filipino's producing power. Increased production stimulated important commercial relations with America, which, with the large increase in tourist travel have been responsible for the rapid growth of Manila and, incidentally, of its traffic system. In its turn the street railway company has reciprocated by providing better service through the expenditure of a large portion of its net earnings for extensions and for new power and car equipment.

A successful struggle has been conducted by the resourceful street railway officials of Manila in protecting their equipment against the natural eccentricities of the Philippine climate, such as torrential rains and the ravages of white ants in devouring wood. Other questions, such as the low per-capita wealth of the city served, present difficulties which can be eradicated only with time. The results obtained by the company in maintaining in the face of these physical and economic obstacles a standard of service unexcelled by the street railway system of the neighboring more densely populated cities of Tokyo, Yokohama and Shanghai in point of promptness, reliability, area served and completeness of equipment should serve as an example of accomplishment to other more highly-favored roads.

INSERT FASTENINGS IN SPECIAL WORK

Our study of insert special work failures and the opinions of engineers expressed in the communications which have followed its publication clearly emphasize that the renewable insert is far superior to the non-renewable insert and that in its setting and fastening, simplicity and accessibility are the most important features. Under heavy traffic most of the plates with any type of insert fastening will come loose at some time during their wear life. Hence, the most desirable fastenings and settings are those which will reduce this number to a minimum, eliminate complications in the rest of the track structure after they do become loose and permit replacements or repairs to be made by the average track laborer. Other important features are provision in the setting to overcome the side thrust of canted trucks and sufficient weight in the insert plate to prevent the peening or cold-rolling action from shearing off or stretching the bolts.

In the past some engineers have demanded fastenings which were too easily released under traffic vibration. Others, going to the opposite extreme, have specified fastenings which practically require the removal of the frog or crossing when refastening or renewal is necessary. While the latter fastening has reduced the number of loose inserts to some extent, it manifestly entails considerable expense when repairs are necessary and may obstruct traffic if the entire piece must be removed. But on light-traffic lines such a fastening has proved very satisfactory and loose inserts are rarely found.

In our insert special work articles we expressed the belief that the setting necessary to meet modern heavy traffic conditions and reduce to a minimum the complications following the loosening of an insert should be the completely or partially-machined bearing type. The approval with which this opinion has been received in the communications sent to us is most gratifying. Obviously a setting which will permit the average track laborer to place an insert in its correct position should prove most satisfactory. It is also believed that a machined-fit, mitered joint between the insert plate running rails and the arms will further assist in obtaining a secure initial setting. It will make the resetting more positive and unquestionably will reduce impact at these points as well as eliminate the tendency of the plate to tilt.

Larger plates with gentle approaches to the narrow throatways, or plates set in special work with the throatways through the arms gently leading up to the narrow throatways in the plate, will gradually right canted trucks and thereby eliminate side thrust. The use of a welder in iron-bound work or provision in the mold of steel-bound work will supply this remedy. This also applies to the method of building up the throatway floor in the rail arm so as to provide a gentle approach to a flange, or equal flange and tread bearing in the insert.

If all of these precautions are taken in the manufacture of track special work, they will have a tendency to reduce materially the number of loose inserts and thus greatly prolong the average life of insert special work.

A WAR STRICKEN CONTRACT

As our readers may know, the London, Brighton & South Coast Railway is undertaking a large work of electrification, including all its suburban lines, and as a whole about 120 miles of lines are to be converted, a task which was expected to cover some four years. Work is already under way and now comes the war to interfere seriously with the original program. As it happens the cable was of Belgian make, and it is not yet clear how much of the material has already been shipped. The cable making was under way a year ago, but of course the works are now closed by the war, and even if not destroyed in the progress of hostilities it may yet be a long time before the supply can be obtained from this source. It is quite certain, however, that the cables can readily be made in England if the strain of the war in the matter of workmen does not become too severe. At all events the American, Italian and Swiss factories could fill the demand, so that this part of the work will not be seriously interfered with.

The general contractors for the equipment, however, ordered the motors and controllers from the Allgemeine Elektricitäts Gesellschaft of Berlin. Nobody can guess intelligently how long the war is going to continue, but, whether long or short, it is quite certain that no British money will go to German manufacturers for a very long time to come. The general contractors will certainly have to cancel their German agreement even if they have not already done so.

In the class of apparatus required for this contract there are relatively few makers having facilities and experience enough to turn out a first-class product promptly. The American makers can meet all the requirements either through their factories here or through the allied British companies. The only other neutral sources where such apparatus could be obtained are in Switzerland, whence egress is troublesome. Moreover, the two great Swiss electrical works are situated dangerously near the German frontier and are somewhat crippled as to labor conditions by the Swiss mobilization. Whether Switzerland can actually keep out of the war remains to be seen. It seems evident, therefore, that the American makers, either directly or through their British establishments, are in line to get this important work, and it goes without saying that the contract in their hands would be filled well and promptly.

This is only one example of the necessary work of the world that is headed this way. When the returns are all in it will probably be found that there are many other German contracts scattered over the world which must be turned over to neutrals, and the aggregate amount of work thus coming to the United States ought to be very considerable, since customers cannot be expected to wait the outcome of an indeterminate and paralyzing struggle like the present one.

POLITICS AND PETITIONS TO COMMISSIONS

One of the most trying duties of the conscientious railway officer is the effort to combat an appeal made to a state commission for political purposes. An operating man can always tell whether petitions for altered service, reduced fares or extended transfer privileges arise out of a genuine local desire for the modification of existing conditions or whether the cause is an attempt on the part of someone to advance his political prospects. But in most cases the adjudicating tribunal is obliged to go through the proceedings just the same, and the burden upon the companies in the weeks prior to municipal and state elections is sometimes most exasperating.

No gain whatever comes from allowing a feeling of irritation at such often needless proceedings to manifest itself on the part of the company, and where cases of this kind reach the public hearing stage, the only thing to do is to marshal the facts, figures and deductions with the same care that would be brought about by an inquiry directed by the commission itself. Fortunately it is seldom a difficult problem in transportation technique to "call the bluff" of the politician who is trying to use the company merely as a pretext for his own selfish ends, and a commission composed of men of insight is not easily deceived as to the motive behind petitions. The chief burden of such proceedings is twofold. They tend to stimulate agitation against the company in various neighborhoods influenced by the politician in charge of the movement, and they add to the existing heavy cares of the operating man and take up his valuable time.

Agitation fostered by self-seekers must be faced with entire frankness, and an open attitude on the part of the company with respect to the reasons for its methods of operation in various localities is the best safeguard against political attack. The public hearing is often a sort of safety valve, at which considerable steam can be let off harmlessly. But after this is done all the pressure against the company will be apt to disappear in the face of facts and man-to-man explanations of service and fare difficulties and the efforts being made by the company to solve them. Where little ground exists for complaint, the occasion may be turned to real account along the line of better acquainting the public with real conditions. There is no relief from the necessity of doing this. It is a part of modern public service, and only by training competent subordinate officials to represent the company in such proceedings can the higher executives of a road be spared some of these burdens.

Commissions are more and more seeing the benefits of informally adjusting complaints through conferences with the interested parties, and the proportion of this class of procedure to the number of formal petitions handled is likely to increase as time goes on. The new Maine public utilities commission act provides that the board may investigate rates or service, "being satisfied that the petitioners are responsible and that a hearing is expedient," and this provision is decidedly in the interest of eliminating lengthy procedure with respect to doubtful appeals of questionable ancestry. If managers make the best of the situation, we are disposed to believe that the commissions will more and more endeavor to protect their dockets against political exploitation.

MORE ABOUT THE CODE OF PRINCIPLES

In last week's issue we suggested the necessity for study of the principles formulated in the code adopted at Atlantic City. To assist our readers in this study a statement has been secured from Thomas N. McCarter, who was chairman of the committee on public relations of the association during the formulation of the code by that committee. Mr. McCarter states some of the ideas which should be suggested by the code of principles or, to use a somewhat technical word, he suggests the proper connotation of the principles. It is not so much what the principles say as what they signify to the rank and file of the industry that will make them effective. The statements made by Mr. McCarter are intended to be merely suggestive. We hope that they will provoke lively discussion.

The code as a whole outlines the big problems of the electric railway industry to-day. Without disparagement to the engineering department which supplies necessary motive power, the equipment department which gives us good cars and maintains them, the transportation department which supplies the human element and keeps it in good training and humor, the accounting department which adds up the nickels and distributes expenses in accordance with the standard classification, and the claims department which insures equitable settlement of accident cases, their problems are less difficult than that of the management which deals with the fickle and inconsistent public. The reason for this is that the departments named deal largely with material and technical matters which follow certain fixed and ascertainable laws. We do not forget that the uncertain human element enters into the work of all of these departments, too, and to that extent complicates their work. But think, in comparison, of the task of defending a property against opposition which possesses the power to confiscate the equity in it and which is apt to be dominated by the ignorant demagogue who achieves cheap notoriety by railing at vested interests!

The electric railways believe that they will get fair treatment from an intelligent and informed public; they fear only ignorance and graft. As we pointed out last week the average citizen does not seem to be able to distinguish between capital and affluence. He puts a railway capitalized at a million dollars in the same class as a millionaire capitalist, and forgets that the capitalization is borrowed money for the use of which regular payments are demanded by the owners. There must come a different point of view before permanent improvement is possible, because the public service commissions can only reflect public sentiment after all. The industry has a big educational job ahead, and it devolves upon the incoming committee on public relations to carry on the work, which so far has resulted in the completion and adoption of the code of principles.

THE FORERUNNER OF TRADE

In a number of recent issues of this paper we have had occasion to comment briefly upon the close sequence between investment and trade which has always been exhibited in the history of the world's commerce. This point is emphasized again by the interesting discussion of European tramway investments by W. J. Clark, published elsewhere in this issue. Up to this time the citizens of this country have been contented largely to look within their own borders for their electric railway investments. The only exceptions of tramway enterprises controlled by American capital, outside of this continent and the United States insular possessions, which we now recall, are a few in South America and in the West India Islands. But the conditions are very different abroad, and before the war London, Brussels and Paris were the centers of electric railway holding companies operating properties not only throughout Europe but the world over.

We are referring to this fact at the present time because it is so closely associated with the South American trade of which so much has been said recently. Our country has never had its logical share of the commerce of South America. It has perhaps been logical that our country, being itself a debtor nation, has been content to devote its enormous resources to domestic enterprises, supplementing them from time to time with foreign capital. The result has been, however, that our manufacturers last year sold to South America only about 12 per cent of her imports and only 6 per cent of our exports, and these percentages were devoted mostly to articles in which we as a nation possessed special advantages.

On the whole, our capital investments in South America have been absurdly small as compared to those of European capitalists. Great Britain and Germany, the commercial powers of Europe, have not only had money for South American investment but have been willing to take a lower interest rate than seems popular here. British capitalists have gone into South America in groups with immense corporate funds for extended investments, while the Germans with less capital have through the establishment of agencies and a diligent study of the South American people and methods carried on their invasion more through a perfecting of trade channels. According to Sir George Paish, formerly the editor of the London *Statist* but now in this country representing the English Exchequer, the total investment of Great Britain in South American countries is as follows: Argentina, $1,600,000,000; Brazil, $739,000,000; Chile, $305,715,000; Peru, $170,865,000, and the other countries, $180,620,000. That these sums have not resulted entirely from operations in the distant past is shown by the fact that during 1913 the investments of Great Britain in these countries amounted to: Argentina, $93,205,000; Brazil, $104,350,000; Chile, $12,920,000; Peru, $4,500,000, and the other countries, $7,195,000. The effect of these investments may be realized when it is considered that in Argentina Great Britain has more than twice the trade of her nearest competitor, Germany, and for all South American countries combined Great Britain far surpasses any other nation.

Vast as the above investments have been, there is still room for additional capital in South America. John Barrett, director of the Pan-American Union in Washington, D. C., believes that the United States can profitably invest $7,000,000,000 in South America within the next twenty years. Colombia with its need of money to build railroads, open mines and market lumber can well utilize $25,000,000 in the next ten years, while Brazil and Argentina should each have $100,000,000 in the near future. There are certainly real opportunities in these and other southern countries for Americans interested in making loans and investments, and creating those conditions of prosperous development which are the forerunner of trade and which lead the beneficiaries naturally to turn for advice and commerce to the nation whose helping hands have thus been outstretched. The sooner our banks realize that investment of American capital in legitimate South American development is the surest way to bind our sister republics to us, the more quickly will we secure that expansion of trade now so strongly desired. The only South American country in which American capital is at all well represented is Brazil, and in 1912 American electrical exports to this country predominated. When this is considered in connection with British investment and trade supremacy in Argentina, the inference is plain.

THE CASE OF THE RAILROADS

The war events still occupy practically all of the first pages of our metropolitan dailies as well as most of the second and third pages, so that between war news and politics little space is left for accounts of current events of importance which are happening in this country. There is no doubt that the present war is a catastrophe to the human race. Its tremendous losses are almost if not quite too great to be comprehended. We intend in no way to depreciate the seriousness of the conditions abroad, but the war should not blind up to serious conditions in this country. In fact, judged purely from the standpoint of money involved, there are certain matters at stake in this country which compare in importance with the stupendous amounts involved in the destruction going on in Europe.

Articles have appeared in some of the foreign papers and have been copied in the American papers estimating the amount of financial injury which has been suffered by Belgium and some of the other contending countries, and speculating upon the sum which the Allies, if successful, will force Germany to pay at the close of the war as reimbursement for the losses inflicted. Is it to be the five milliards of francs, or the $1,000,000,000, which Germany demanded of France at the close of the Franco-Prussian war, or is it to be two times, or five times, or ten times this amount? This is necessarily a question of the future, but a hearing has been going on in Washington during the past few weeks which has involved property worth not merely $1,000,000,000 but more than twenty times that amount, yet it has attracted comparatively little public attention.

We refer, of course, to the hearing before the Interstate Commerce Commission which involves directly the investment in the steam railroads of the country, which has been conservatively estimated at $20,000,000,000, and only less directly the investment in the electric roads, which has been estimated at from $3,000,000,000 to $4,000,000,000, as well as that in the manufacturing industries which depend for their prosperity upon the supply of material to both of these classes of roads. We include the electric roads because while their interests are not as closely bound up in the rate hearing at Washington as are those of the steam roads, yet favorable action there and a clear-cut statement on the part of the commission of the needs of the steam roads would undoubtedly give moral support to the demands of the electric roads on the state commissions and municipal authorities for fairer treatment.

Both classes of railroads have explained their needs to the public and to the properly constituted authorities. With both the present situation has been brought about largely by the same causes—the higher cost of materials and labor and higher taxes. With both the conditions arising largely from the war have involved the necessity of paying higher interest rates in the future. With both the question of an advance of rates is not one which can be postponed indefinitely. In the steam railroad field, for instance, the companies are facing the necessity of providing some method of refunding their short-time notes, debentures and other bonds which have an early maturity. It has been estimated that $547,000,000 of securities of this kind must be refunded during the next three months alone, and of this amount $303,000,000 represent the applications of three so-called typical systems, namely the Pennsylvania, Baltimore & Ohio and New York Central systems. This sum, $537,000,000, which is to be accounted for within the next few months, is equal to more than half of the entire national debt of the United States, yet how much public attention has this fact attracted?

While waiting for a decision in the steam railroad situation it is a satisfaction to record a step in the right direction as regards the electric roads. After an extended and carefully conducted hearing, the Massachusetts Public Service Commission has granted to the Middlesex & Boston Railway permission to charge a 6-cent fare, as described in another part of this issue. We hope that this ruling will suffice as a precedent to other commissions to grant similar relief to companies in other states. The need is great not only so far as the railways and their stockholders are concerned but to the public as well, because the public depends for its prosperity upon the maintenance and extension of proper transportation facilities. We believe that if there was a wider knowledge of the conditions under which our transportation systems are suffering, there would be little difficulty in securing the relief so anxiously sought and urgently needed.

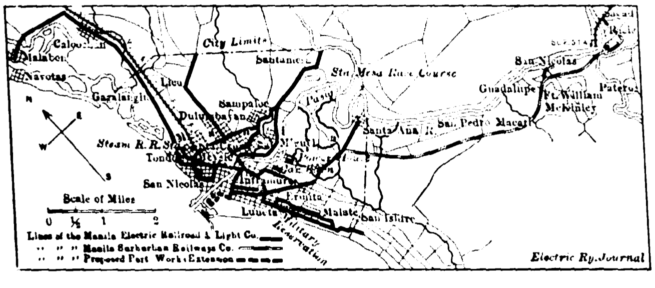
Electric Railway Service in Manila

Historical, Operating and Engineering Features of the Electric Railway Properties in a Large Oriental City—Many Difficulties Overcome in the Construction of the Railways

Electric railway, lighting and power service in and about the city of Manila, P. I., is furnished by the Manila Electric Railroad & Light Company and the Manila Suburban Railways Company, the properties of both companies being operated under the supervision of The J. G. White Management Corporation of New York.

In 1903 Charles M. Swift of Detroit obtained a franchise from the city of Manila to build and operate an electric lighting, power and railway system in that city. The only electric and transportation facilities of importance in Manila at that time were owned by two Spanish corporations, La Electricista and Compania de los Tranvias de Islas Filipinas, the former having been organized in 1892 and furnishing electricity for city lighting and private use, and the latter, organized in 1885, operating horse-car lines in the city and a steam dummy line to Malabon.

The properties and franchises of both Spanish companies were purchased and together were turned over with the new franchise to the Manila Electric Railroad & Light Company, which was incorporated under the laws of the State of New Jersey. In 1906 a franchise for a suburban railway and electric system to Pasig was obtained and turned over to the Manila Suburban Railways Company of Connecticut. The property which was subsequently constructed, as well as that of the first-named company, was constructed under the supervision of J. G. White & Company, Inc., of New York.



RAILWAY SERVICE IN MANILA—ELECTRIC ROAD CHART

TERRITORY SERVED

Since the American occupation in 1898 Manila has undergone a steady and rapid growth until it is now known as the "Pearl of the Orient" and has a population, including suburban districts, of about 350,000. Due to its increased wealth and commerce it has been made a regular port for the most important trans-Pacific steamships, thus providing the city with frequent and regular transportation service to and from the United States and principal oriental points.

The main business portion of the city lies north of the Pasig River and includes the principal retail business street known as the "Escolta." The city is in general quite low, a large portion being only a few feet above tide water, and abounding in "esteros" or waterways, which overflow at high tide and flood the low lands. These periodically inundated areas are constantly being reclaimed by materials brought from the higher districts east of the city.

A large population is supported in the rich farming districts surrounding Manila and served by suburban lines which carry passengers and market commodities to and from the urban markets. The development of suburban railway facilities has played an important part in the rapid growth of outlying districts which were previously reached only by various primitive modes of transportation, such as the two-wheeled cart drawn by the "carabao," the native water buffalo, which is commonly used in the islands as a draft animal.

The principal suburban line terminates at Pasig, a city of about 20,000 inhabitants, located about 6 miles southeast of Manila. This line serves various intermediate communities including Fort William McKinley, the principal military post on the islands. Another suburban line reaches Malabon, about 4 miles north of Manila, and runs over the route originally used by the steam dummy line.

Climatic conditions have aided greatly in the development of car riding for both business and pleasure purposes. During the greater part of the year the heat of the day renders walking any distance difficult and very unpleasant. Even before the construction of the Manila railway system the natives had developed the riding habit; in addition to the horse trams there were in 1903 about 5000 private and public vehicles in the city, most of which were drawn by native ponies.

The Filipino is very fond of amusement and his tastes in this regard are accountable for a considerable volume of railway traffic. Various amusements are frequently provided, such as evening band concerts on the "Luneta" (public park), cockpits, "fiestas" of various kinds on numerous holidays, and frequent games of baseball in which the natives have taken very great interest since its introduction by Americans.

OPERATING STATISTICS

During 1913 the Manila company carried 16,952,975 revenue passengers, 5,933,767 transfer passengers, and 1,234,202 passengers were carried free. The total of these is 24,120,944. The respective figures for the suburban company are 3,984,948, 382,736 and 88,648. The grand total of passengers for the year was 28,577,276, or approximately 520,000 per mile of track.

The total revenues from transportation of the two companies were $712,941.04 and $128,726.29 respectively; the corresponding car-miles operated were 3,356,165 and 493,804, and the corresponding car-hours 456,687 and 50,739. Taking the population served by the railways at 325,000, the transportation income per inhabitant is found to be $2.58. The transportation revenue for the city lines was 21.2 cents per car-mile or $1.56 per car-hour. The respective figures for the suburban line were 26 cents and $2.54.

The operating expenses for the city lines were $351,156.39, that is 10.45 cents per car-mile or 76.8 cents per car-hour. Of this the labor cost for trainmen for passenger, freight and express cars was $84,167.45, or 2.5 cents per car-mile, or 18.4 cents per car-hour. The operating expenses for the suburban line were $51,023.34, which corresponds to 10.3 cents per car-mile or $1.01 per car-hour. The labor cost in the latter case was $8,801.16, which is 1.78 cents per car-mile or 17.4 cents per car-hour.

RAILWAY CONSTRUCTION

The actual construction of the properties involved many difficulties due to the great distance from sources of American manufactures and the necessity of using untrained native labor requiring more than ordinary supervision. The older parts of the city presented unusual problems in overhead construction, due to narrow streets on which the second stories of buildings on either side frequently extended beyond the curb line.

Since the completion of the original constructions in 1905 the properties have undergone more or less continual extension and betterment, until they now comprise nearly 55 miles of standard gage track, almost all of which, within the city limits, is in paved streets. In macadamized streets and those without pavement, tracks are constructed of 70-lb. T-rail, creosoted redwood or native hardwood ties and stone ballast. In city streets having more permanent types of paving, track construction is of 92-lb. grooved girder rail laid on concrete foundations. The overhead trolley wires are supported mostly by means of native hardwood poles. There are also quite a number of steel poles set in concrete, and in more recent construction most of the poles are of concrete.

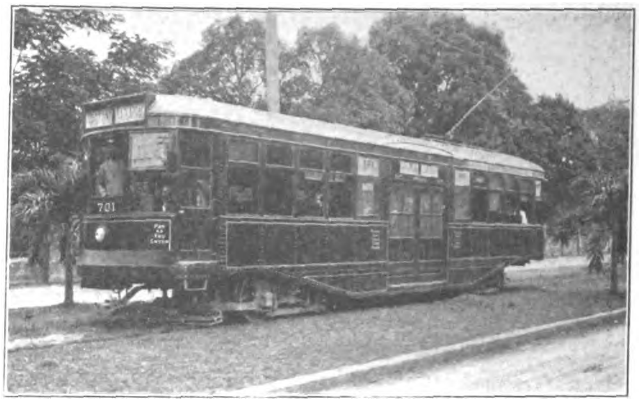
The offices, shops and carhouse are located at Calle Zobel and San Marcelino and are of modern concrete steel construction. The power house, also of concrete and steel, is near by on the Isla Provisora. The shops are very completely equipped, due principally to the distance from the United States and consequent necessity of handling all repair work in Manila.

ROLLING STOCK

The rolling stock of the Manila companies includes a total of 140 cars of the following types: sixty-seven closed double-truck motor cars, fifty-four single-truck and five double-truck open motor cars and fourteen general utility cars.

Passenger cars are divided into two sections to provide for separation of first and second-class riders, those of the first class being seated in the front section. On cars having end platforms, first-class passengers enter and leave at the front platform and second-class passengers at the rear. Cars are provided with two fare registers, one for each class.

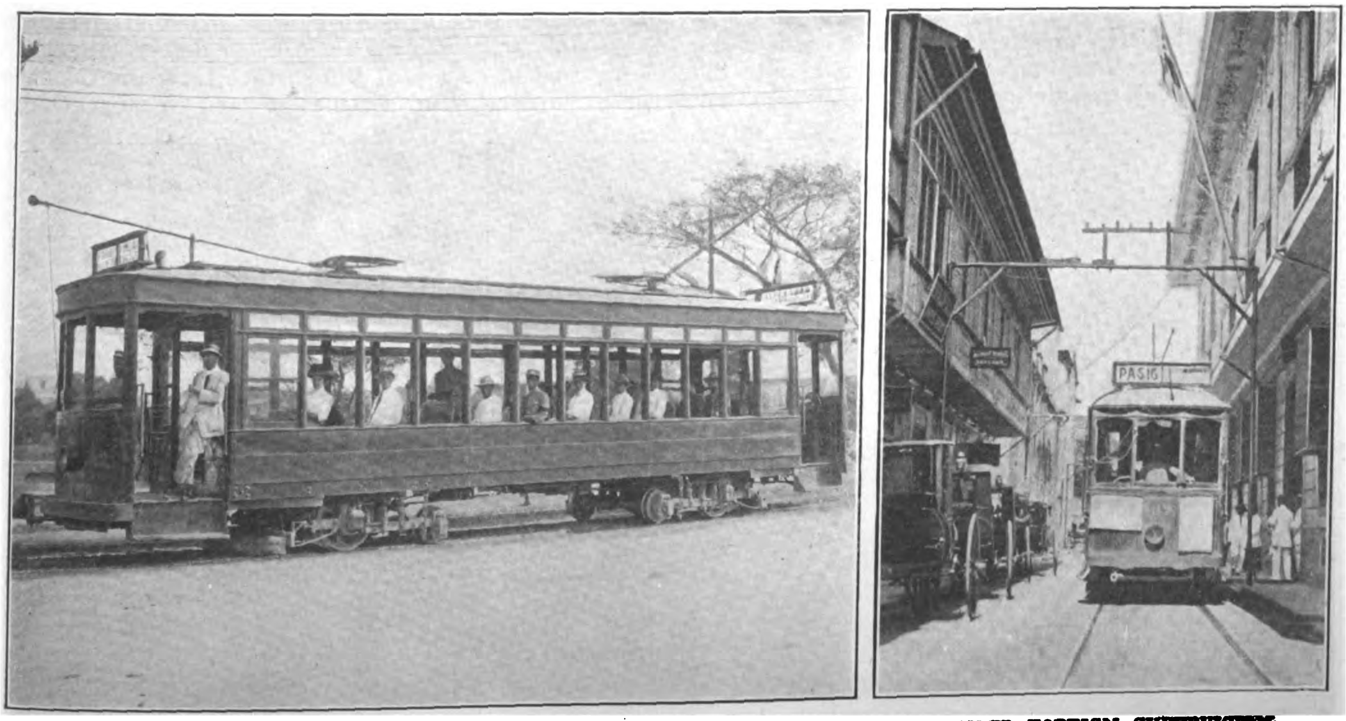
After a great deal of experimenting with various types of cars shipped to Manila from the United States, the company has adopted as standard for city service a semi-steel center-entrance car constructed in its own shops in Manila. These cars, twelve of which have been built, are very similar to the center-entrance cars in service on the lines of the Brooklyn Rapid Transit Company. They have steel underframes and sides and curved T-iron overhead construction, are 45 ft. in overall length, have a seating capacity of fifty-four persons, weigh 18 tons, are equipped with electrically lighted routing signs at either end, and are mounted on Brill 39-E maximum-traction trucks. Six of the center-entrance cars are equipped with Westinghouse 68-C motors, and the remainder with GE-203 motors. All twelve are operated by K-36 single-end control.



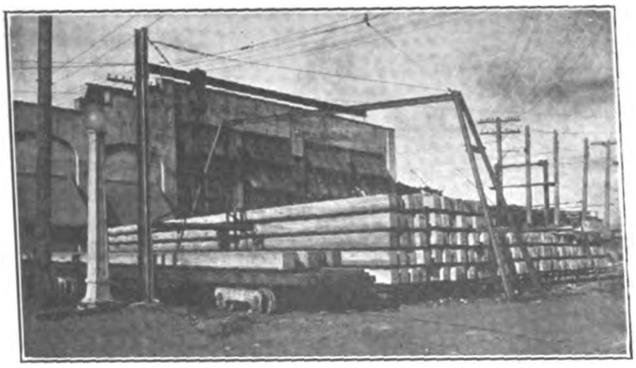
RAILWAY SERVICE IN MANILA—NEW SEMI-STEEL CENTER-ENTRANCE CAR

The stepless principle has proved especially adaptable to Philippine service owing to the small stature and short limbs of the average Filipino, and provides convenience to native women carrying large market baskets on their heads. The center-entrance cars are able to make the regular schedule speeds and are very popular with the public. They lend themselves particularly well to the separation of the two classes.

The monitor roof has been abandoned in favor of the arched type owing to troubles experienced with leakage of the former at times of heavy rainstorms which are



RAILWAY SERVICE IN MANILA—VIEW OF CAR BUILT BY PHILIPPINE NATIVES UNDER FOREIGN SUPERVISION—TYPICAL NARROW STREET SHOWING OVERHEAD PIPE CONSTRUCTION



RAILWAY SERVICE IN MANILA—CONCRETE POLES

frequent in Manila during the rainy season, which is from June to October.

RATES OF FARE

The following rates of fare, expressed in terms of United States gold, are in force on the city lines: For first-class passengers, at all hours, 6 cents cash or a 5½-cent ticket; for second-class passengers, 5 cents cash or a 4-cent ticket with a special 3-cent cash fare in effect before 7 a.m.; special ticket fares for school children, 3 cents first class and 2½ cents second class.

The suburban line to Malabon is divided into three zones with fares as follows: First zone to Maypajo, same as city lines; second zone, Maypajo to Sangandaan, cash fares first class 5 cents, second class 2½ cents; third zone Sangandaan to Malabon, same fares as on the second zone.

The suburban line to Pasig is also divided into three fare zones with the following rates in force: First zone, to Santa Ana Junction, same as on city lines; second zone, Santa Ana to Fort McKinley, cash fares, first class 5 cents; second class 2½ cents, and special school ticket fares of 2½ cents and 1¼ cents for first and second class, respectively; third zone, Fort McKinley to Pasig, cash fares, first class 4 cents, second class 2½ cents.

On all lines one-half cash fares for children are in effect.

The company provides special market-car service on some of its lines, the cars having space for market baskets, etc., for which a small extra charge is made. The heavy market travel begins between five and six in the morning and continues until noon. A complete system of inspection is in force for checking the registration of fares; the amount of inspection required has been considerably reduced however by the use of center-entrance cars.

OVERHEAD CONSTRUCTION

Climatic and local conditions have presented difficulties in electric line construction which were unexpected by American engineers. Untreated crossarms shipped to Manila from the United States were found to have a life of only about two years; when creosoted, their life is increased to about six years.

In the case of poles, American and Australian woods rotted or were destroyed by white ants so quickly as to bring about the complete abandonment of their use. A native wood called "ipil" was then adopted and proved very satisfactory except for its scarcity and high cost. This wood is very hard and close-grained, and is heavier than water. An ipil pole lasts from twenty-five to thirty years and costs, in a 30-ft. length, about $18. The company's standard pole is now of concrete, 1:2:3 gravel mixture, reinforced with four ⅝-in. twisted rods which are laced together with No. 12 galvanized iron wire. These poles have a 12-in. square butt and a 6-in. square top, are 30 ft. long and cost $11.50 each. The company has several hundred of them in service at the present time.

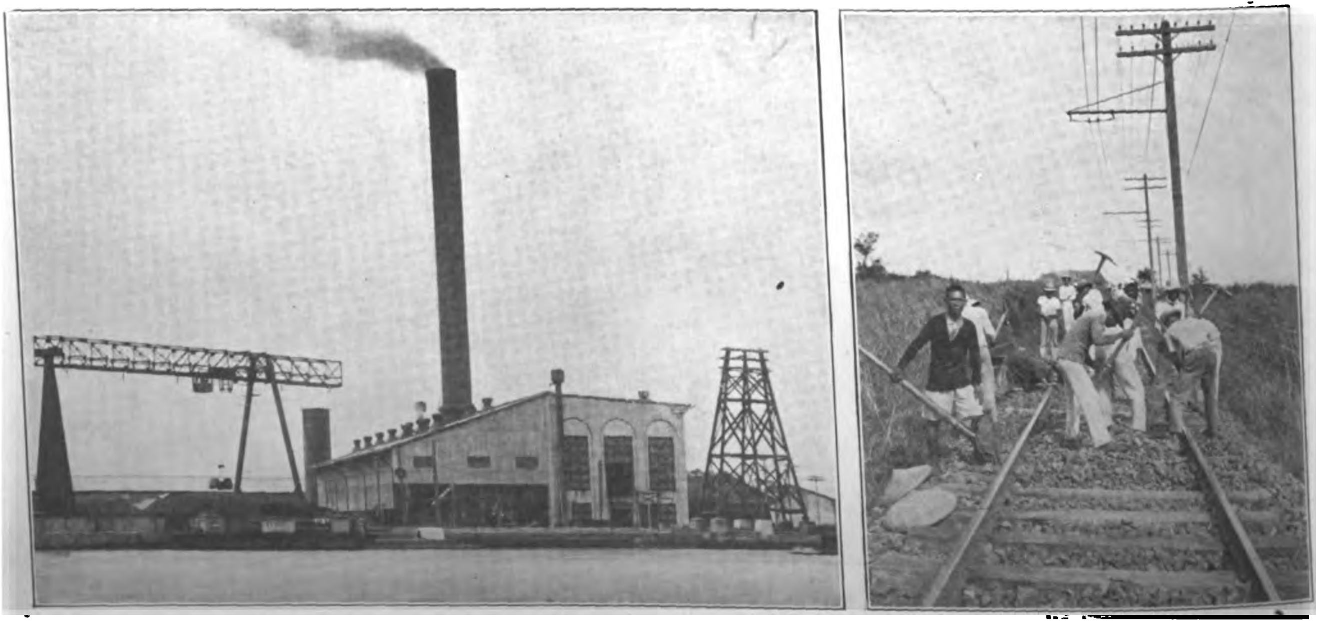
Heavy winds during typhoons reach velocities as high as 100 m.p.h. and usually cause troubles with electric lines by blowing branches of trees across the wires, etc.

POWER GENERATION

The initial plant installation of the Manila company was completed in 1904 and included three 750-kw Westinghouse-Parsons turbo-generators and eight 400-hp British Babcock & Wilcox boilers. In 1905 an additional 1500-kw unit together with three 500-kw and one 300-kw rotary converters were installed to provide for the railway load. The old La Electricista plant was completely abandoned in 1906.

Since then the company's power-plant equipment has been increased from time to time until the rated generating capacity now amounts to a total of 10,000 kw. The present generating equipment is all turbine driven and includes two 750-kw Westinghouse-Parsons units, one 1500-kw Westinghouse unit, one 2000-kw Westinghouse unit and two 2500-kw Allis-Chalmers units.

All condensers are of the surface type, the complete equipment including circulating and vacuum pumps



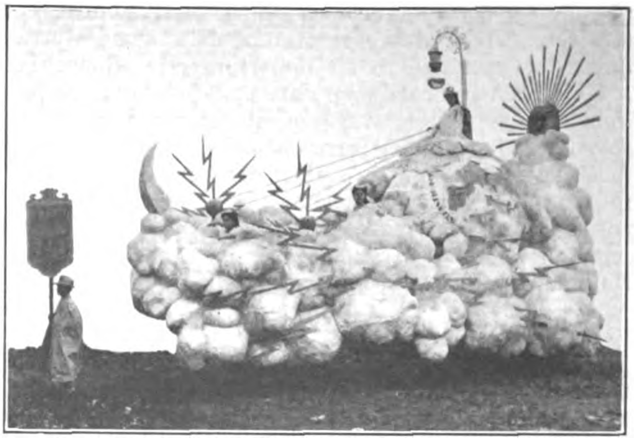
RAILWAY SERVICE IN MANILA—POWER HOUSE—TRACK GANG ON SUBURBAN LINE having been furnished by Alberger & Company. The exciting equipment comprises two 37½-kw direct-connected Westinghouse exciters, one 50-kw Westinghouse exciter direct connected to a three-phase induction motor and one 100-kw Allis-Chalmers exciter direct connected to an induction motor. All excitation is furnished at 125 volts.

The railway equipment in the main station includes four 500-kw Westinghouse rotary converters and one 1000-kw Westinghouse motor-generator set. One 300-kw rotary converter is located in the substation at Fort McKinley and supplies direct current to the interurban line at that point. The same substation includes equipment for distribution of alternating current for lighting and power to the military post and the city of Pasig.

The boiler plant equipment includes twelve 400-hp Babcock & Wilcox water-tube, hand-fired boilers served by a steel stack 9 ft. in diameter and 175 ft. high. Ten of these boilers are of British manufacture, and two were built in the United States; all are equipped with superheaters. Feed water is heated by two closed heaters of the Goubert type.

The power plant is adjacent to navigable water, as shown in the accompanying illustration, and coal is transferred directly from barges onto the coal pile by means of an Alliance coal conveyor driven by a d.c. motor and having a capacity of 20 tons per hour.

The price of coal has recently been advancing until coal now costs the Manila company $4.80 per ton for Chinese fuel delivered on the pile. Australian coals of higher heating values have been tried, but their use has been given up due to excessive cost and unreliable deliveries. Engineers of The J. G. White Management Corporation have several times investigated the use of fuel oil both on the Manila property and on the Philippine railway located on the islands of Cebu and Panay, with the conclusion that under present conditions the use of coal is more economical. The Manila company has recently obtained a franchise for a water-power development on the Caliraya River about 40 miles southeast of Manila, and it is expected that this development, when completed, will solve the fuel problem. The steam plant, however, will be operated as an auxiliary.



RAILWAY SERVICE IN MANILA—CARNIVAL FLOAT RECENTLY SHOWN BY THE LOCAL COMPANY

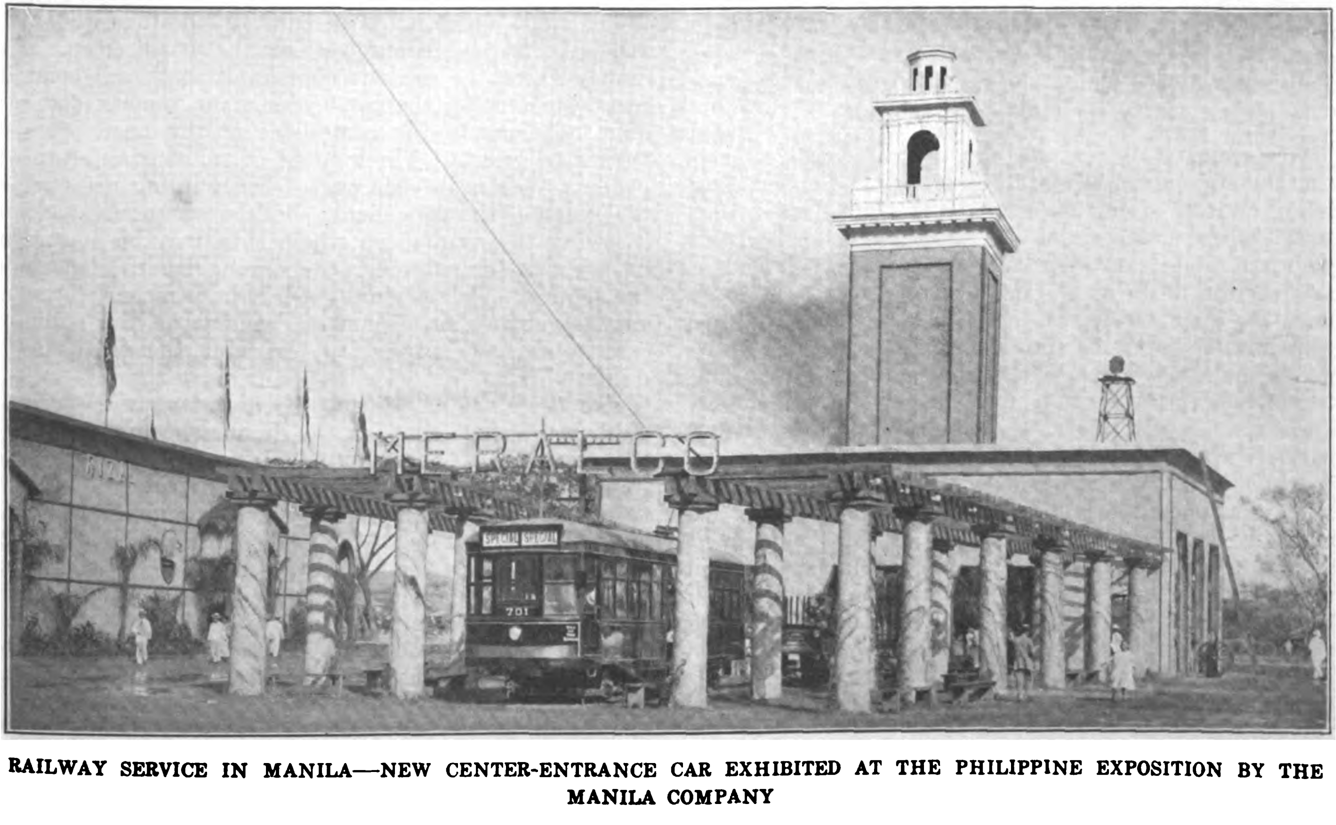
During 1912 the maximum peak on a five-minute basis was 6480 kw and the annual load factor amounted to 32 per cent.

LABOR CONDITIONS, ETC.

The various department heads of the local operating organization are mostly Americans and Englishmen. Native Filipinos constitute the greater part of the company's labor except that nearly all of the carpenter work is done by Japanese.

The company has established regular classroom instruction for native employees and has found verbal instruction the most satisfactory method of teaching. Student trainmen usually spend an apprenticeship period of about sixty days under instruction before being placed in the company service.

Filipinos make good motormen and conductors after being thoroughly trained in their duties, and intoxication is practically unknown among them. They develop into good firemen, switchboard attendants, wiremen and linemen, and make excellent workers under competent supervision. The company's policy is to advance native employees to positions of greater responsibility and



RAILWAY SERVICE IN MANILA—NEW CENTER-ENTRANCE CAR EXHIBITED AT THE PHILIPPINE EXPOSITION BY THE MANILA COMPANY remuneration in accordance with their abilities and services. Under this system many Filipinos have risen to be foremen and to fill important clerical positions.

Motormen and conductors are paid 8½ cents per hour. The average hourly wage of all labor on the weekly payroll including platform men is 7½ cents. While these rates are low in comparison with corresponding rates in the United States, they are very high as compared with labor wages in China and India. The most common languages spoken among company forces are English, Spanish and "Tagalog," the native dialect.

WELFARE WORK

The company has followed the lead of American companies in the establishment of facilities for athletic games among employees and the provision of free medical service.

Two and a half years ago a baseball team was organized and later a band of seventy-two pieces. The "Meralco" baseball team, composed of native employees, has twice won the amateur championship of the islands and last February won the amateur championship of the Orient, having defeated the champions from Miji University, Japan. The ball team and the band have both been very effective toward promoting the physical and mental development of the native employees.

The company employs a doctor who takes care of sick and injured employees at the company's expense. Tuberculosis is quite prevalent in the islands but since the American occupation the number of cases has been greatly reduced by improved sanitary conditions.

ORGANIZATION

The personnel of the executive and operating organization is as follows: Charles M. Swift, president; Frederic H. Reed, vice-president; John H. Pardee, vice-president; C. Nesbitt Duffy, vice-president and general manager; T. W. Moffat, secretary; R. B. Marchant, treasurer; L. S. Cairns, assistant general manager; W. M. McGeachin, manager electric department; J. C. Rockwell, manager railway department, and J. B. Russell, auditor.

Effect of War on British Tramways

Enlistment of Men Forces Reduction in Service, Compensating for Falling Off in Traffic

According to Sir A. Stanley, managing director of the Underground Electric Railways, Ltd., London, England, the total of employees of the District London Electric, Central London and City, South London Railways who had gone to war up to Sept. 19 was 936. The result of this drain on the body of employees was to reduce the train service on the District Railway by 2 per cent and on the Tube Railway by 26 per cent. As regards the London General Omnibus Company, the number of men in the service up to the same date was 3399. Consequently it reduced the number of omnibuses in service, averaging 300 to 450 per day. The early closing hour of 10 o'clock has materially affected the traffic after that hour and all services are being reduced. The company now has in training a sufficient number of men to replace those who will enlist from time to time and also to bring the railway and omnibus services up to a sufficient strength to deal with the traffic. It is not expected that any necessity will arise for considering the use of women for any of the work heretofore done by men, and the company has taken steps to care for the wives and families and other dependents of men who have gone to the front.

A. W. A. Chivers, inspecting officer of the British Electrical Federation, Ltd., London, states that the outbreak of the war had an adverse effect upon the traffic receipts of the companies comprising the federation, although the falling off in revenue was not so great as expected. For the first month since the beginning of hostilities the traffic receipts showed a decrease of 4.05 per cent. The effect on the receipts varied in different parts of the country. In some places revenue increases have been recorded owing to activities caused by the war in certain industries, while in other sections increases have been noted on account of activities brought about by the formation of new military stations. The decreases are most marked in seaside towns. This is largely caused by the fact that the railways have been required by the government to furnish military transport service, and with the temporary suspension of excursions and the issuing of cheap tickets has resulted in a reduction in the number of seashore visitors during the middle part of the holiday season. Unfavorable weather conditions also have an adverse effect upon the revenues of certain lines.

During the mobilization period all soldiers, sailors and nurses in uniform were carried free of charge, which in some cases interfered with the ordinary traffic. On Sept. 16 about 1240 men and twenty officials left their employment to join the national forces. The reduction in service to meet the traffic requirements has enabled all undertakings to continue without the necessity of discharging any employees. Moreover, by curtailing the service, economy has been effected in the operating expenses.

On the outbreak of war the management promptly issued notices granting facilities to all men wishing to join the colors and assuring them that upon their return they would be reinstated in their former positions or would be found suitable employment with the federation. The management has also instituted a mutual aid fund for the relief of all employees' dependents. The officers and men contribute a small sum weekly out of their earnings and the companies contribute an equal amount with a minimum of 3d. per week per man employed. Thus far the experience with the fund indicates that the contributions are ample to meet all calls likely to be made upon it. The fund is administered by a specially formed committee at the head office. The managers of the various companies and local committees representing the employees make reports and recommendations to the committee at the head office in regard to grants. The amount of relief granted to dependents varies in each case. The guiding principle is that none of the dependents shall be worse off financially owing to any man on whom they may be dependent having left for service. The arrangements made with the salaried officials who have left to join the colors also vary according to circumstances, but all the affiliated companies have agreed to pay half the salary as a minimum.

The Tramway & Railway World in its issue of Oct. 8 published a table showing the number of employees and the per cent of the total number employed who had joined the colors up to Sept. 30. The total number of tramway employees now serving England in the army and navy is 10,688. In the order of the number of employees in service the first five ranking corporations are Glasgow, 1500; London County Council, 1294; Manchester, 740; Birmingham, 697; Liverpool, 600, and Bristol, 499. The first six companies in the order of the percentage of the total number of employees at war are Kilmarnock, 41 per cent; Dover, 38 per cent; Brighton, 33.33 per cent.; Burnley, 27.5 per cent; Glasgow, 27 per cent and Liverpool, 26 per cent.

The Code of Principles

Why the Code Was Prepared—How It Should Be Used—Brief Discussion of Each Principle by the Chairman of the Public Relations Committee Which Drafted the Code

BY THOMAS N. M'CARTER, PRESIDENT PUBLIC SERVICE CORPORATION OF NEW JERSEY

The electric railway industry has a code of principles prepared after much study and discussion and designed to show clearly what the industry believes to be the fundamental economic basis of its business. Such a code of principles is needed as a guide both to the practice of electric railway companies and to the ruling of courts and commissions. To be effective it must have not only the passive and verbal assent of the railways but their active, constructive co-operation as well. The code must also commend itself to the public by its reasonableness and its fairness.

At no other time in the history of the industry has there been so logical a reason for a declaration of principles or so great a necessity for it. Under the early forms of franchise, contracts were matters of barter between individual companies and communities. Contracts were unscientific, illogical and uneconomic. They generally lacked provision for the protection of capital investment by failing to permit adjustment of rates of fare to suit varying conditions and by limiting the length of franchise term. The tendency to ignore the conditions which must inevitably accompany the termination of a franchise has been general, the intention being apparently to shirk the responsibility by passing it on to future generations.

The present epoch is one of adjustment. It is a crisis in the development of the electric railway industry, and it has become essential that the railways should be able to present their case in such a way that the commissions will realize that there is a railway, as well as a public side to regulation.

The Century Dictionary states that a principle is "that which is professed or accepted as a law of action or a rule of conduct." It is also "a truth which is evident and general." The combination of these two elements in the code is essential to its general acceptance. Whenever a body of people comes to consider certain general principles to be sound and worthy of practice it formulates a creed or code. This crystallizes the existing sentiment and conviction and forms the basis for active and effective propaganda. The electric railways are now in this creed-creating period.

The association has accepted the code of principles. The practical question now arises as to the next step to be taken. It will not be sufficient to compliment the committee on public relations and the sub-committee on the code of principles upon the excellent work which has been done and then proceed to pigeon-hole and forget the whole subject. The code must now be promulgated by educational campaigns of one form and another as outlined in the committee's report. It must be studied by every man in the industry who has any influence with the public.

To further this study the following statements amplifying and illustrating the principles have been prepared with a view to stimulating interest and giving in concise terms the principles underlying the declarations.

I. The first obligation of public utilities engaged in transportation is service to the public. The first essential of service is safety. Quality of service must primarily depend upon the money received in fares. For this reason it is necessary that the rate of fare should be sufficient to permit the companies to meet the reasonable demands of patrons and to yield a fair return on a fair capitalization.

The prime consideration of all transportation service should be safety. Following this, the public is entitled to the best service which can be given for the fare received. Good service means equitable adaptation of available facilities to the needs of the community. It involves cars kept as clean as the nature of the business permits, courteous attendance, reasonable seating capacity and convenient and direct routes so far as the needs of the entire community are concerned. All of this is on the assumption that the public is willing to do its part in granting the use of the streets and operating conditions which, with reasonably good management, will insure a fair return upon the investment. In demanding good service the public must remember that it is the greatest good to the greatest number that is the desideratum. The running of unnecessary cars or the furnishing of unnecessary seats in one direction lessens the facilities that can be furnished in another.

The public is becoming more exacting in demanding more and better cars and longer rides for which it does not offer a larger fare. Frank R. Ford in an article in the ELECTRIC RAILWAY JOURNAL for Oct. 10 showed that the railways are meeting the costs imposed by the demand for better service through more efficient management, but that the net results of this economy are being appropriated by the public in increased taxes. He states further that the development of and investment in the industry are not keeping pace with the increase of traffic. This is due to the small incentive offered to capital to invest in electric railway properties.

II. Regulated private ownership and operation of electric railways is more conducive to good service and the public welfare than government ownership and operation because the latter are incompatible with administrative initiative, economy and efficiency, and with the proper development of cities through the extension of transportation lines. The interests of the public are fully protected by the authority given to regulatory bodies.

Public ownership and operation of electric railways under the present political conditions of American cities would be disastrous. The principal expense in electric railway operation is for labor. The labor expenses are larger in proportion to the total expenses in electric railway work than in any other quasi-public utility, like the distribution of water, gas or electric light. Municipal operation of electric railway systems would injure the credit of the municipality which attempted it because the operation would not be conducted on economical lines, and it would add to the power of the local political machine because it would greatly increase the number of positions to be filled by the party boss. The number of employees in government service is already very great, involving large political patronage. It would be unfortunate if this number should be augmented by the vast army of electric railway employees.

From the standpoint of efficiency there is practical difficulty in securing economical administration of public office. Even in our federal enterprises where politics plays a much less important part than in city and state governments this is the case. Private ownership and operation under fair and intelligent regulation tend to safeguard the rights of the public while affording the stimulus necessary to the fullest development of the industry.

III. In the interest of the public and good service local transportation should be a monopoly and should be subject to regulation and protection by the state rather than by local authorities.

That local transportation service should be conducted as a monopoly is a fact requiring no proof in these days. Direct competition between electric railways is absolutely destructive. The interests of the public, the companies and the investors are all best served by regulated monopolies, thereby making possible, on the one hand, the elimination of duplication of investment and the attainment of increased efficiency of operation, and, on the other, the guarantee of protection against unreasonable costs of competition to be eventually saddled upon the public.

The present tendency in regulation is entirely toward state regulation as opposed to municipal regulation. One reason for this is that few important public utilities are confined to one municipality. The regulation of such utilities by a large number of independent municipal commissions would work great hardships on the utilities and would appear to give no advantage to the public. Moreover, under our system of government a state commission is more apt to be independent of politics than a city commission.

IV. Short-term franchises are detrimental to civic welfare and growth because they ultimately check the extension of facilities and discourage good service.

Where a franchise is issued for a definite term with no provision for its renewal, the public utility company must invest a large amount of money in property in the street which cannot be removed and may be useless when the franchise expires. The shorter the term the greater the difficulty which the company would experience in trying to recoup its investment during the franchise period. If an electric railway could be built in final form at the beginning and no improvements should be required during the life of the franchise, it would be possible for a company to determine definitely the extent of its investment which it would have to amortize each year so that its stockholders would receive back their capital at the end of the franchise term. But in any growing community the transportation facilities have to be increased with the needs of the public, and any plan of continuous amortization of the investment so that it will all be extinguished at the end of the franchise is not practicable.

The theory upon which the short-term franchise has been defended has been that the public cannot trust the company for a longer period of time. But if the public will not trust the company, why should it expect that the company will trust the public to give fair treatment to the company at the end of the franchise term? Every electric railway franchise should have sufficient life to warrant the company in building and developing a good railway system, and it should contain a provision by which if the municipality should not renew the franchise it will pay the company the fair value of its property.

V. In order to render good service, electric railways must be allowed to earn a fair return on a fair capitalization, and the foundation for this result will be obtained if the issuance and sale of securities representing such fair capitalization shall be legally authorized on such terms as will produce the requisite funds.

That a return commensurate with the risks involved in the business must be offered to investors, if sufficient capital to properly develop the electric railway industry is to be secured, is axiomatic. This is a condition and not a theory. Money is a commodity, varying in price, due to the prevalence of different conditions at different times. Sufficient elasticity in the selling price of bonds and obligations, by way of discount, must be allowed to meet the conditions prevailing at the time the disposition of securities is consummated. Otherwise, the new money, so necessary for development, cannot be procured. In short, the electric railway business, while differing in some aspects, is subject to the same laws of economic trade as are all other business propositions.

VI. Securities which have been issued in accordance with the law as it has been interpreted in the past should be valid obligations on which an electric railway is entitled to a fair return.

The valuation upon which an electric railway is entitled to a fair return should take into account the fair investment that has been required to develop the property. The value should not be merely the physical valuation whether depreciated or not but should include all reasonable expenses that have been incurred in the progress of the art to bring the condition of the company up to what it is to-day. For instance, the expenses that arose from the substitution of cable power for horse power and later of electricity for the cable are legitimate parts of the cost of enabling a railway to render its service to-day. Such changes were instituted primarily for the benefit of the public, and it should not accept these benefits without rendering due returns to the investors whose capital made their provision possible. The non-recognition of securities that have been legally issued in the past causes both the company and the public to suffer.

VII. The relation of adequate wages to efficient operation should always be recognized, but electric railways, being public servants regulated by public authorities, should be protected against excessive demands of labor and strikes.

While every industry should receive all of the protection from the authorities which it needs in the peaceful conduct of its legitimate business, a public utility has a special right to make such a demand because it supplies a public necessity under the regulation of the public. No one is obliged to take service with an electric railway company unless he desires to do so, and a strike among the employees of such a railway company should be regarded with as much public disfavor as a strike in the police department of the municipality.

VIII. The principle of ownership of securities of local companies by centralized holding companies is economically sound for the reason that the securities of the latter have protection against the varying business conditions of a single locality or company and because money for construction and improvements can thus be more readily obtained.

The principle of distributed risks and of economies by doing things by wholesale apply to electric railways as well as to other lines of business. A holding company can operate a number of properties more economically by dividing the overhead charges among them than each property can be operated individually. It can also issue securities which will be more attractive to the investor because his risks are not concentrated in any one property. Hence an electric railway operated by a holding company can give a better service, other conditions being equal, than can a company which has to maintain an independent organization.

IX. In the appraisal of an electric railway for the purpose of determining reasonable rates, all methods of valuation should have due consideration.

When a property is valued for the purposes mentioned, the question is not altogether one of original investment, present investment or reproductive cost new. For instance, if the actual investment is less than the present value a return upon this investment alone denies the right to use the difference between these values and hence impairs the property right to a reasonable return upon the whole. Each of such valuation figures, however, is persuasive evidence of the real valuation of the property. The fact is that, since the property has no fixed market value, the determination of a just valuation means the consideration of as many items as possible, such as the original cost of construction, the amount expended for permanent improvements, the reproductive cost new, the amount and market value of stocks and bonds, the going concern value and all intangible elements that have served to bring both the physical properties and the business to their present stage of development.

X. Full and frank publicity should be the policy of all transportation companies, to the end that proper information may be available to the investor and the public.

Owing to their public character electric railway companies believe that the public has a right to a complete knowledge of their accounts and affairs. Supervised and regulated as the companies are by commissions and doing a public service, they have nothing to conceal but everything to gain by a frank and open policy. Some people believe that every electric railway is rich and prosperous because of the amount of money invested in it. These people forget that an income must be earned on this investment and that labor and materials cost money. There is a vast difference between the million dollars capital of an electric railway company and the nickel which it receives as carfare, and the interest on this capital must be paid out of the margin left in the nickel after operating expenses have been paid.

Investigations of Boiler Explosions

In a recent editorial *Power* strongly advocates that the law, which the committee of the American Society of Mechanical Engineers is to recommend as a model for legislation to restrict the slaughter and damage occasioned by the abuse of boilers and other pressure vessels, should provide for a thorough investigation as to the cause of every serious accident to a boiler.

The board of boiler rules, or some other competent body, should be authorized to carry out this examination. empower to subpœna witnesses, to call for books, papers and other pertinent evidence, and be required to submit a report within a reasonable time, showing the cause and manner of the explosion, and fixing the responsibility. The owner and operator of a plant in which an explosion occurs should be required immediately to report it to the investigating authorities, and penalties should be provided for failure to do so. Insurance companies also should be required to report claims for losses. In this way a vast amount of valuable and authentic information regarding explosions would be accumulated, stress thrown upon the causes which most frequently produce explosions, and a way pointed out to avoid them.

The Chesterfield Tramways Committee, Chesterfield, England, is issuing tokens for free transportation on its tramcars and motor buses to Belgian refugees who are quartered in the district traversed by its lines.

Chicago & Joliet Railway's Safety Campaign

Illustrated Lectures Are Conducted to Interest School Children—Co-operation of Automobile Owners Is Sought

In conjunction with the heads of the city and parochial schools of Joliet, Ill., and the Illinois Steel Company, the Chicago & Joliet Electric Railway has conducted a series of lectures with slides and motion pictures, in the interest of a safety campaign among school children. The pictures shown included reels and slides pertaining to safety methods and precautions used at the Illinois Steel Company's mills, followed by slides and reels pertaining to street and street railway accidents and their prevention. To give the children something to carry away with them and remind them of the lessons of the "safety first" lecture, 6000 blotters calling attention to the urgent need of the safety habit were distributed among them.

The campaign this year was the second of its kind, and the company believes that it has greatly assisted in eliminating accidents, particularly to children. While it is difficult to determine the exact extent to which these lectures have served in promoting safety, it is interesting to note that not a single child has been injured by the street railway within the corporate limits of Joliet since the first safety lecture was given, more than a year ago. It is also interesting to state that out of a total attendance of 958 children at the Joliet schools, the average attendance at the safety lectures was 725. The railway company arranged to transport the children from the various schools to the point where the lectures were given. There were eight lectures in all, requiring a total free car mileage of 314.4, with total car hours of 110, which included the time the cars were held waiting for the completion of the lecture.

CAMPAIGN WITH AUTOMOBILE OWNERS

In conjunction with the safety campaign among school children, another campaign was conducted among automobile owners. The following is a copy of circular letter which was sent to all automobile owners in the city of Joliet.

"As an automobile owner your interests are so identical with our own as regards the avoidance of accidents, we ask for your co-operation in our endeavor to reduce accidents to the lowest possible minimum.

"In the past nine months there have been thirty-five collisions between automobiles and street cars on our system. More care would have avoided these accidents, which, as you are aware, result in more or less injury to persons and damage to property.

"Our car men are instructed always to think of safety first and use of good judgment by having cars under control at dangerous places so as to take no chances.

"Will you kindly bear in mind, and also instruct your drivers, to use all possible care and look and listen when operating across or near car tracks? Also caution them in regard to operating machines past cars when passengers are alighting.

"Too much speed is the cause of most collisions.

"The co-operation of all automobile owners is being solicited to obtain the results we know you would yourself wish to see, and we shall appreciate your assistance."

With this letter to owners of automobiles, a blotter containing safety cautions and suggestions was included. In both of these campaigns the railway company had the full co-operation of the local newspapers, which gave considerable publicity to the various lectures and the results of the campaign.

Electrical Operation On the B., A. & P. Ry.[*]

The Electrification of this Ore Handling Line Results in Greater Operating Efficiency and In a Saving of More Than 20 Per Cent in Operating Cost

BY J. B. COX, RAILWAY ENGINEERING DEPARTMENT GENERAL ELECTRIC COMPANY

The Butte, Anaconda & Pacific Railway was built in 1892, principally for transfer service between the ore mines in Butte and a smelter in Anaconda. The tracks connecting these two cities are approximately 26 miles in length, but the yards and sidings which were included in the recent electrification of the line bring the total mileage up to about 90.

Work on the electrification began in the spring of 1912, and the first electric locomotive was run experimentally in Anaconda on May 14, 1913. Two weeks later a double-unit electric locomotive took over the regular day service of hauling the ore from East Anaconda yards to the concentrator yards, the distance between which is approximately 7 miles. The load per trip in this service was gradually increased from sixteen cars to twenty-five cars, which is to be the standard for the present. The average time for the up-hill trip with twenty-five cars is about twenty-six minutes so that eight trips per shift are easily made, making possible a delivery of 200 cars, an increase of slightly more than 108 per cent over what had been possible for the crew with steam locomotives. These loaded ore cars average from 70 tons to 72 tons each, making the trailing load for a twenty-five car train from 1750 to 1800 tons.

The regular passenger service between Butte and Anaconda was taken over for electrical operation on Oct. 1, 1913. The distance between the stations—Anaconda to Butte—is 25.7 miles, and the schedule for the trip is one hour. No change has been made in this time, though were it desired a reduction of 20 per cent would be possible with the electric locomotives. As had been done in the freight service, the steam engineers in the passenger service were transferred from the steam to the electric locomotives with but little previous instruction, and after the first day or so were left mostly to themselves. It may be of interest to note here that on the day shift, averaging four trips per day, no passenger train came in late on account of engine trouble during the first five months. There follows a comparison of the delays to the passenger trains for the month of June, 1913, under steam operation with the same month in 1914 under electrical operation.

	No. of Trains	Meeting Points, Hr.Min.	No Power, Hr.Min.	Engine Failure, Hr.Min.	Lost Running Time, Hr.Min.	All Causes, Hr.Min.
Steam, 1913.......	272	15 49	.. ..	.. 44	4 13	20 46
Electric, 1914.....	280	3 54	.. 27	.. 24	.. 25	5 10
Decrease	8*	11 55	.. 27*	.. 20	3 48	15 36
Percentage of saving due to electrical operation.	2.94*	75%	....	45%	90%	75%

*Increase.

On Oct. 10 a double-unit electric locomotive was put in the day-freight service on the main line between East Anaconda and Rocker, a distance of 20.1 miles. The standard train that had been hauled on the trip was about fifty loaded ore cars weighing approximately 3500 tons gross, and the average running time of such trains where no stops were made was about one and one-half hours, corresponding to an average speed of approximately 13.4 m.p.h. In the beginning the electric locomotive took only the standard train but it made the trip without stop in about one hour, corresponding to an average speed of 20 m.p.h. The ruling gradient on the westward trip is 0.3 per cent grade, and with a fifty-five car train the steam locomotive made about 7 m.p.h. The electric locomotives with similar trains now make about 16 m.p.h. on the same grade. The weights of the trains hauled by the electric locomotives on this run have been gradually increased up to sixty-five loaded ore cars averaging about 71 tons each, making the trailing load about 4620 tons. Adding 160 tons for the weight of the double-unit electric locomotives and 20 tons for the caboose makes a gross train weight of approximately 4800 tons.

The remainder of this class of freight traffic was gradually taken on during the months of October and November, thus completing the electrification of the main-line service. A comparison of the month of June, 1913, under steam operation, with the same month, 1914, under electrical operation, shows that with a slight increase in the total tons of ore hauled the average tonnage per train was increased from 1761 to 2378, or 35 per cent, thus decreasing the average number of trains per day from 12.5 to 9.3. The average time per trip during steam operation was approximately two hours and twenty-five minutes, while with the electric locomotive it was approximately one hour and forty-five minutes, showing a decrease of forty minutes, or 27.5 per cent. These figures represent the time put in by the crews between Rocker and Anaconda, the distance being 21.8 miles. The result of these improvements is that the overtime in this particular service has been decreased 73.5 per cent and the total time 42 per cent, resulting not only in greater economy to the railway company but in shorter and easier hours for the crews.

During the year's operation difficulties especially attributable to the higher potential have been negligible, and while there have been occasional instances of arcing and flashing or short-circuits due to ordinary causes, the resultant damage has been really smaller than might be expected from a like occurrence on a 600-volt installation of equal capacity.

The original brushes supplied in the motors chipped badly, and before all these had been replaced it was often found when the units were brought in for regular inspection that some of the brushes were broken entirely into pieces, and while there was evidence that a flashover might have occurred at some time no harm had resulted other than the blowing of the motor fuse, on the replacement of which the engine was continued in service until its regular time for inspection when the cause of the fuse blowing would first be discovered.

The fact that the locomotives continued in service thus is sufficient evidence of the harmlessness of the arc-over, and in no instance of the kind has any real damage been done. The locomotives have made from 25,000 miles to 50,000 miles each and without exception the motors are in excellent condition. The wear on the commutators is imperceptible and the general performance of the entire equipment is quite as satisfactory and promising as that of any railway equipment with which the writer has had experience in service of similar kind.

---

[*] Abstract of a paper presented at the Pacific Coast meeting of the American Institute of Electrical Engineers, Spokane, Wash., Sept. 10, 1914, and printed in the *Proceedings* of the Society for November.

The overhead construction has been satisfactory and a recent examination of the trolley wire shows no indication of unusual wear. The roller pantographs are operating quite successfully, the average life being from 10,000 to 12,000 miles per roller. Where a double-unit locomotive is operated, the two pantographs are connected electrically by a main bus line, and the average current collected by each, when ascending the grades with standard loads, is from 350 amp to 400 amp. Two pantographs operating in multiple thus will collect more than double the current that can be successfully collected by a single pantograph for the reason that sparking is usually due to the momentary breaking of contact between the trolley wire and the roller caused by hard spots in the line. When two pantographs are operated in multiple both do not encounter these hard spots at the same instant, hence one of the two is more apt always to be making good contact, so that the flow of current is not so frequently interrupted and the sparking is greatly reduced. The double units operating on Smelter Hill were run experimentally for several days with only a single roller making contact with the wire, the operation being quite successful with the single roller collecting an average of 650 amp to 750 amp while running at 16 m.p.h. or 17 m.p.h. and from 800 amp to 1000 amp during the accelerating period in multiple. The sparking was not serious except at hard points in the line, and with two rollers in multiple there should be no difficulty in collecting 500 amp or 600 amp per roller. This at 2400 volts should be equal to the requirements of any ordinary locomotive unit.

The bearings first used in the rollers were provided with ordinary bushings lubricated with oil, but when the bushings became slightly worn the oil was thrown out along the spindle and had to be replenished at comparatively frequent intervals. Later, roller bearings with grease lubrication were installed with excellent results. As yet these have not been in operation a sufficient length of time to definitely indicate how long they may be expected to last, but it would appear that the bearing will last much longer than the roller and that the attention required for the adjustment and lubrication of the bearing or the roller will be negligible.

Only minor changes have been made in the personnel of the maintenance or operating departments of the railway on account of the electrification and there has been no reduction in salaries or wages. An extra man with electrical experience was placed in the shops to supervise the electrical repairs to the locomotives and three linemen were retained for the maintenance of the trolley system.

Three steam switching locomotives used for concentrating the ore at, and distributing supplies from, the Butte Hill yards have been continued in this work. Another steam locomotive is used on the Georgetown branch and a fifth one operates at intervals over unelectrified tracks at the Anaconda end. Approximately 20 per cent of the total locomotive miles now being operated is by these five steam locomotives, the cost of which is upwards of 40 per cent of the total cost of all locomotive performance.

From the regular monthly locomotive performance sheets of the railway company the principal saving resulting from electrification appears to be due to the partial substitution of electric power for coal, at the rate of $150,727 per year. The approximate price of coal for locomotives is $4.25 per ton. With a single exception, that for depreciation of equipment which is taken at $2,711 per month for electric locomotives as against $1,340 for steam, every item of expenditure in the locomotive performance sheet shows a substantial percentage of decrease in favor of electrical operation.

The total saving from locomotive performance alone is at the rate of $237,582 per year, to which should be added credit for handling an increase of traffic at the rate of 13,938,136 ton-miles per year, or 8.77 per cent more than was handled by the steam locomotives during the period compared. To this saving from locomotive performance should be added the saving from trainmen's wages, which is at the rate of $31,146 per year, or a decrease of approximately 21 per cent, due largely to the elimination of overtime. This makes the total saving from these two items $268,728 per year. From this should be deducted $10,839 for maintenance of the distribution system, leaving $257,889 as the net saving per year due to electrical operation.

The roadmaster states that it is quite evident that the electric locomotives are much easier on the track at curves but that there is no noticeable difference on tangent track, and that while sufficient time has not yet elapsed to form definite conclusions, present indications lead him to expect that any difference relative to his work will be favorable to the electric locomotives.

Arranging the items of expense in the order of usual appearance in the summary of a standard locomotive performance sheet and placing them on a yearly basis results as follows:

Item of Operating Expenses	Steam, 1913	Electric, 1914	Decrease, 1914	Per Cent Decrease
Fuel and power.....	$315,235.74	$164,508.70	$150,727.04	47.81
Repairs	124,787.90	92,278.08	32,509.82	26.05
Enginemen's wages.	104,461.18	71,225.88	33,335.30	31.80
Enginehouse expense	29,907.80	18,638.38	11,269.42	37.68
Water	4,953.66	1,193.70	3,759.96	75.90
Lubricants	9,751.44	4,942.32	4,809.12	49.30
Other supplies	5,823.52	4,552.36	1,271.16	21.83
Total locomotive performance ...	$594,921.24	$357,339.42	$237,581.82	39.93
Trainmen's wages...	147,632.30	116,486.00	31,146.30	21.10
Grand total	$742,553.54	$473,825.42	$268,728.12	36.19
Ton-miles hauled ...	158,917.720	172,855,856	13,938,136	8.77

The total cost of the electrification, including a change of signal system on Smelter Hill, an extra motor-generator set recently installed at Anaconda, interest during construction and all incidentals due in any way to the electrification, was in round numbers $1,200,000. This does not include the stepdown transformers which are the property of the power company, but on the other hand no deduction has been made for the salvage due to the elimination of twenty steam locomotives.

If a correction be made for the item of depreciation (which does not appear in full on the 1914 records) the total net saving would be reduced to $242,299, which is equivalent to 20.02 per cent on the entire cost of the electrification, to say nothing of the increased capacity of the lines, the improvement in the service and more regular working hours for the crews.

If taken on the basis of the increase shown in net operating revenue, or operating income, this percentage is slightly greater, the rate of increase per year for these items being $288,150 and $282,016 respectively. The estimate on which the decision to proceed with the electrification of the road was made placed the annual net saving expected at 17.5 per cent of the cost, so that the results financially have been quite as satisfactory as the general performance of the equipment.

To assist in caring for the large number of wounded brought to Vienna, from the Galician battlefields, the Vienna Tramways has converted sixty trailers into hospital cars which were made available for four stretchers each by removing the seats. The wounded soldiers are transported in trains of four cars consisting of an ordinary motor car and three of these converted hospital cars.

The Bow Trolley on the Indianapolis & Cincinnati Traction Company's Lines

The Bow Trolley, Which Is Widely Used in Europe, Has Received Very Little Consideration in This Country, But Its Ability to Reduce Arcing Has Proved Very Satisfactory on This Interurban Railway

A recent inspection of the overhead contact system on the lines of the Indianapolis & Cincinnati Traction Company has disclosed the fact that the bow trolleys installed on all of the railway company's cars have proved to be thoroughly satisfactory after nine years of operation. This form of contact device, notwithstanding its extended use in Europe, has received but little attention in the United States, and an account of the Indianapolis & Cincinnati Traction Company's experience with it affords a considerable amount of interesting data.

The line, which has been described in detail in previous issues of the ELECTRIC RAILWAY JOURNAL, extends from Indianapolis, Ind., to Connersville, Ind., via Rushville, a distance of 58 miles; and from Indianapolis, Ind., to Greensburg, Ind., via Shelbyville, a distance of 50 miles, making the total length of the road 108 miles. There are three grades, each about 1 mile long, with gradients of 2 per cent, 2½ per cent and 3 per cent. The remainder of the line has no gradients of more than 2 per cent.

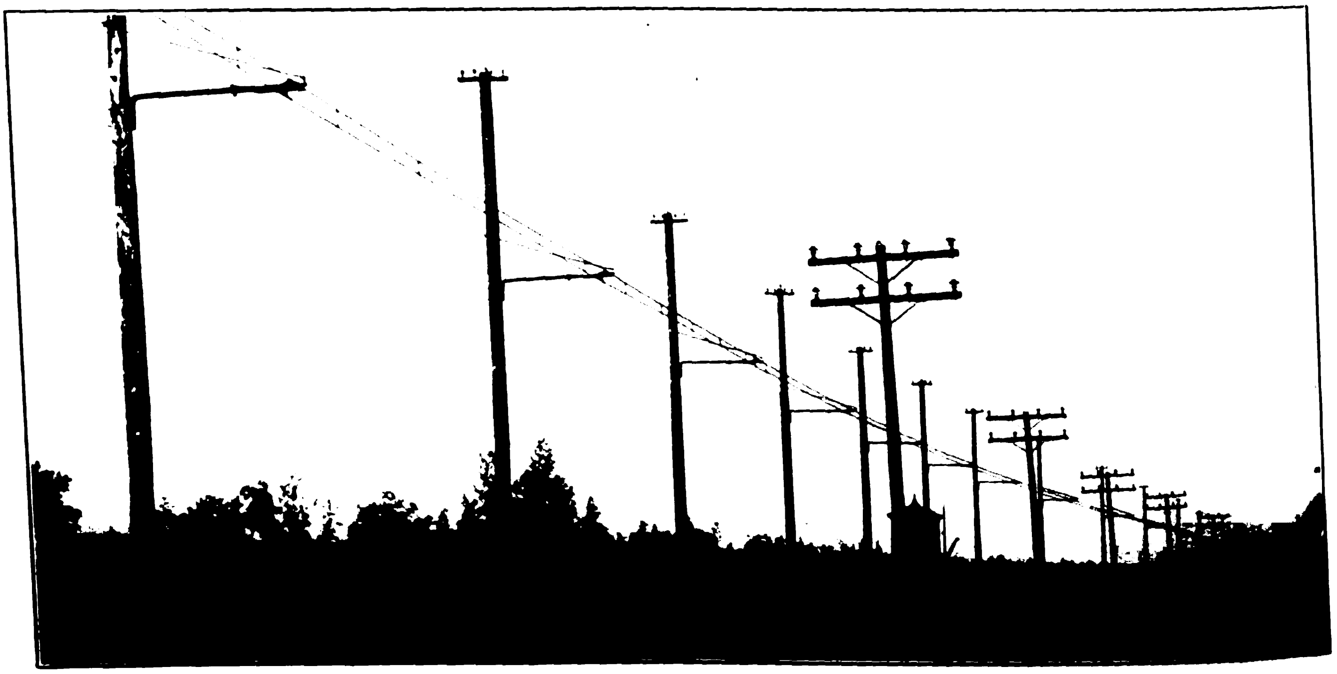
The passenger cars are 55 ft. long, and have four Westinghouse 100-hp motors, 22.61 gear ratio, 37-in. wheels and Westinghouse "AB" control. Each weighs, complete with equipment but without load, 50 tons. These cars are operated as single units. The freight cars are 55 ft. long and are equipped with four 100-hp motors having a gear ratio of 16.67 and mounted on 37-in. wheels. These freight cars are equipped to pull freight trailers.

An hourly schedule is maintained by the passenger cars. Considerable freight traffic is handled, one train being run each way on each division. The maximum speed of passenger cars is approximately 60 m.p.h. on straight, level track and while drawing power from the trolley.

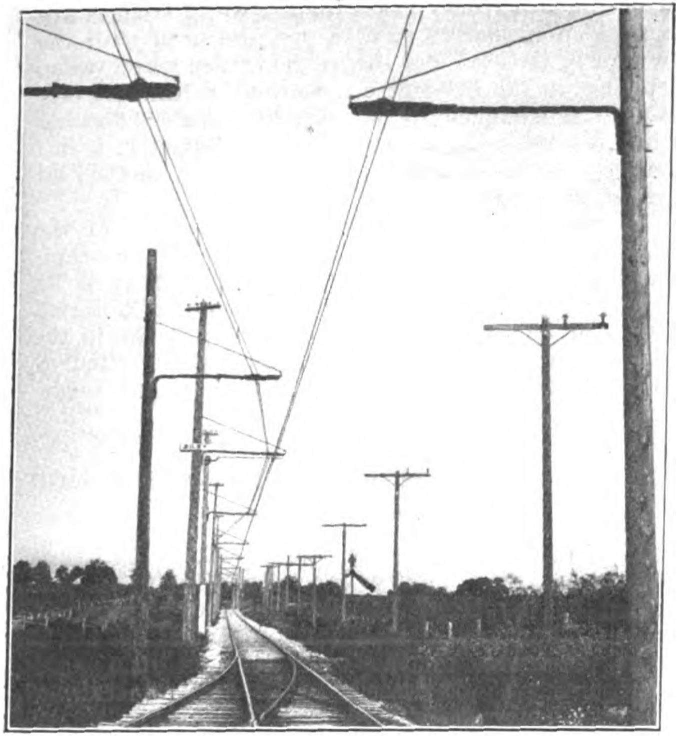
The main trolley line is made up of No. 000 standard grooved wire supported on catenary construction with rigid hangers. It is supplied with single-phase current at 3300 volts, except for about 3 miles within the city limits of Indianapolis where, upon the lines of the Indianapolis Traction & Terminal Company, ordinary span-type construction is used with 500-volt direct current. All of the electrical equipment was installed by the Westinghouse Electric & Manufacturing Company. C. L. Henry, president, and G. W. Skipton, master mechanic and superintendent of overhead, state that the overhead construction has been eminently satisfactory. During the nine years of operation on the 41-mile division from Indianapolis to Rushville and the seven years of operation on the remainder of the road, there have been only six breaks in the trolley wire. In a recent breakage of the messenger wire, the trolley wire, then in use more than nine years, accepted the additional strain without difficulty. Traffic was held up but twenty minutes, or until the two ends of the messenger cable could be tied around near-by poles. During the few hours required to repair the messenger wire no difficulty in maintaining traffic was experienced.

No difficulty has been encountered from the rigidity of catenary construction, and "hard spots" in the overhead lines are unknown. It is claimed that a considerable amount of inherent flexibility is present in the construction, and the operating officials do not believe that any additional flexibility is required. However, the satisfactory operation secured with the rigid construction is considered to be due largely to the inherent flexibility of the bow trolley which is used.

Slack is taken out of the line at no regular intervals. In a number of cases this condition is cared for by straightening up of poles at the curves, since it was found that, after several years of operation, the poles have leaned slightly. Straightening the poles has per-



INDIANAPOLIS & CINCINNATI BOW TROLLEY—VIEW SHOWING RIGID CATENARY OVERHEAD TROLLEY CONSTRUCTION

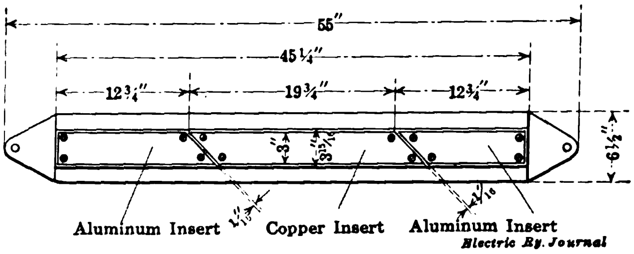


INDIANAPOLIS & CINCINNATI BOW TROLLEY—VIEW SHOWING RIGID CATENARY OVERHEAD CONSTRUCTION

formed the same function, in a particular locality, as the renewal of 1 ft. or 2 ft. of the copper trolley wire. However, it is expected that, during the coming spring, sections will be removed from the trolley wire on several of the tangents.

Bow Trolleys

The bow trolleys installed on the cars have, in the opinion of Messrs. Henry and Skipton, rendered excellent service. It has, however, been suggested that the weakest point of the bow trolley ought to be near the base. At present the weakest point of the construction is where the bow, which holds the contact shoe, connects with the poles or uprights. In one or two cases the trolley has failed at this point, and the uprights have torn down the messenger wires, striking them when the car was moving at a high speed. The company is reinforcing the bows at the present time by inserting a tube about 18 in. long inside of the bow to strengthen it at this point.



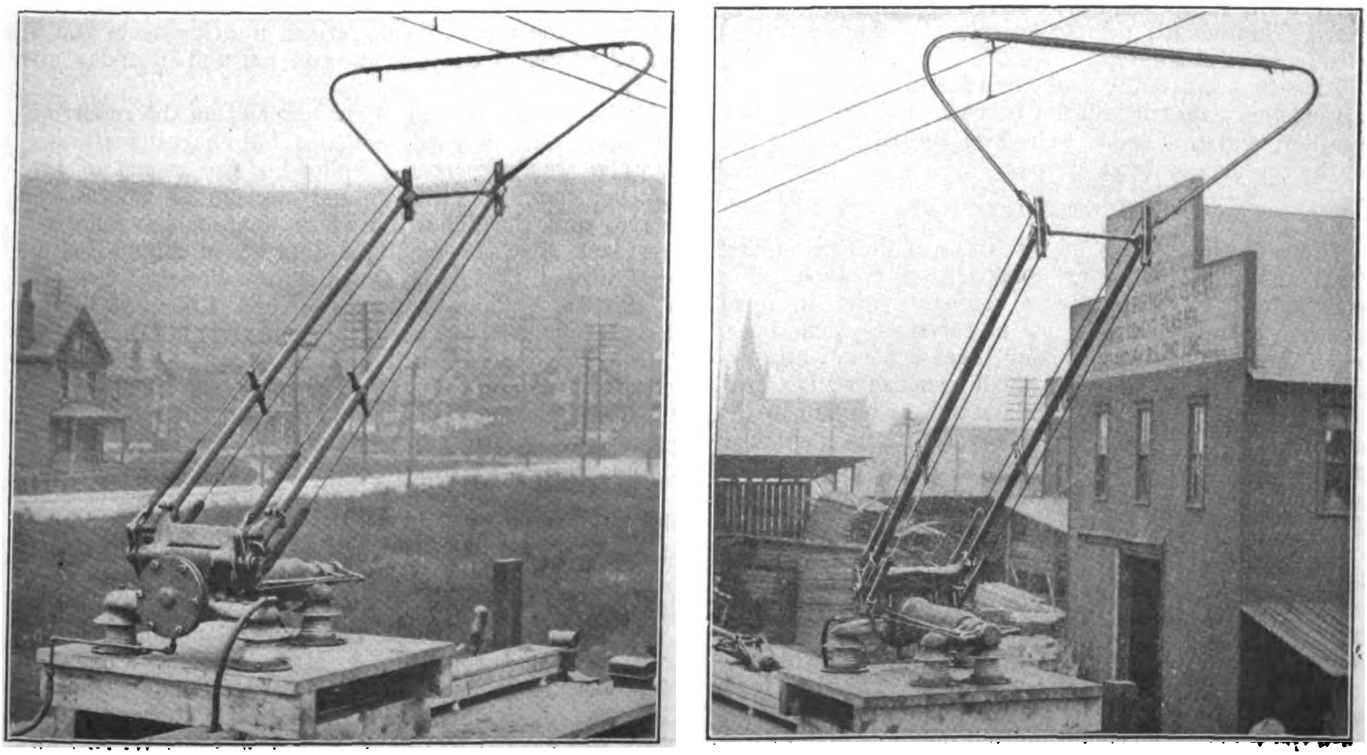
Electric Ry. Journal

INDIANAPOLIS & CINCINNATI BOW TROLLEY—APPROXIMATE OUTLINE OF BOW-TROLLEY SHOE SHOWING INSERTS IN FACE

In addition, since the trolley wire has to be raised at railroad crossings from the normal height of 18 ft. to provide a clearance of 22 ft. the bow trolley does not operate reliably because it is adjusted for the 18-ft. height of trolley wire. It is, of course, primarily important that the cars should always have power at railroad crossings, and instructions are in the hands of the transportation men to use the wheel trolleys at all such points. It is impossible, however, for the bow trolley to be made to operate reliably under different heights of trolley wire. The wheel trolleys with which the cars are equipped are ordinarily used with the 500-volt system in the city of Indianapolis.

Pressure of Contact on Trolley Wire

A pressure of 12 lb. is used for the contact of the bow trolley against the trolley wire, and the trolleys are adjusted to give this. The trolley wire is prone to deflect when the bow trolley is against the wire, as no steady strains are used except on the curves. This arrangement presented the possibility of the contact strik-



INDIANAPOLIS & CINCINNATI BOW TROLLEY—FRONT AND REAR VIEW OF BOW-TYPE TROLLEY ing the messenger cable, and the pressure on contacts was therefore reduced until this danger was eliminated.

The actual weights of the detailed parts of the bow trolley, not including the base, are as follows:

Slide or contact, without inserts	13 lb.
Copper inserts	3½ lb.
Aluminum inserts	4¾ lb.
Tubing	7 lb.
Poles or uprights	32 lb.
Necessary clamps for holding tubing	5 lb.
Suspension rods (four)	4 lb.

These details, with the necessary screws for holding the copper inserts in place and the several bolts required, will give a total of about 70 lb. for the bow trolley, excepting the base.

CONTACT SHOES

The diagram on page 1053 shows the general form and dimensions of the contact shoes and also the relative position of the copper and aluminum inserts. The aluminum inserts are of extruded aluminum, purchased from the Aluminum Company of America at a price varying from 46 cents to 58 cents per pound, depending upon the market conditions. The two aluminum contacts at both ends of the slide are ⅕ in. thick.

The copper insert at the center slide is of a fairly hard grade of rolled copper, ⅕ in. thick. The life of the copper inserts is, under ordinary conditions, about 2000 miles. During sleet storms, however, it is customary to replace these copper inserts, and sometimes the entire contact, after one day's operation, or about 400 miles of service. But in excellent weather the life of the copper inserts exceeds 2000 miles.

The life of the aluminum inserts at both ends of the slide is a little less than that obtained from the copper inserts at the middle of slide. The operating department estimates this to be about 1800 miles on the same basis as the estimated life of 2000 miles given for the copper inserts.

The trolley wire of the Indianapolis & Cincinnati Traction Company is not staggered, and difficulty exists at times due to the wire wearing grooves in the copper contacts, requiring replacement within three or four days. There are instances where a groove has been worn in one of the aluminum inserts at either end of the slide. This condition is to be corrected as the trolley wire is to be staggered.

There is used on the contacts a heavy grease of such a consistency that it will not become liquid even in hot weather, and this tends to reduce the frictional wear on the contacts and trolley wire.

CURRENT COLLECTION

The collection of current by means of the bow trolley from the rigid catenary construction is thoroughly satisfactory to the railway company, and in good weather there is said to be no arcing. Sometimes, when the weather is rainy, and there is some water deposited on the trolley wire, small arcs are visible, particularly in the evening. This seems to be due to the water on the trolley wire. It occurs at no particular place on the trolley wire; that is, arcing is no more apparent at the hangers than between the hangers. The wheel trolley is used at times on the high-tension trolley, but only in cases of emergency. Where there is water on the trolley wire, the arcing with the trolley wheel is somewhat more noticeable, particularly at the hangers. The theory held is that the ears of the rigid hangers prevent proper contact of the trolley wheel.

Wear on the No. 000 trolley wire has caused no trouble to date. Samples taken from the trolley wire indicate the remarkable condition that only one-fifth or one-sixth of its useful life has been utilized notwithstanding that it has been steadily in use for nine years.

The standard trolley bases for the wheel trolleys are mounted on insulators similar to those used with the bow type of trolley. The life of the trolley wheel, when operating on the 500-volt d.c. sections within the city limits of Indianapolis, is between 2000 and 3000 miles. It has the following characteristics: diameter, 6 in.; bearings, ¾-in. diameter, 1¾-in. length; method of lubrication, graphite grease.

The members of the operating department of the Indianapolis & Cincinnati Traction Company are unanimously in favor of the bow trolley on account of its flexibility. The difficulty of adjustment for different heights of trolley wire and of operating a car in the reverse direction with the bow trolley is admitted by the operating men, but it is felt that the many advantages outweigh these objections.

Railway Electrical Engineers Convention Proceedings

An account was published last week of the early sessions of the Railway Electrical Engineers convention at the Hotel LaSalle, Chicago. The meeting on Thursday, Oct. 29, was opened by H. R. Bucks, chairman of the committee on axle lighting equipment. It described the general tendency of steam railroads toward axle lighting in preference to other systems, but called particular attention to the high cost of maintenance for the dynamos as compared with other parts of equipment. That for the storage battery, for instance, was found to amount to only about one-half that for dynamos. The report of the committee on rules for car wiring included specifications for complete systems to conform with the underwriters' rules. This report was read by Chairman F. W. Everett, Atchison, Topeka & Santa Fé Railroad.

J. L. Minick, chairman of the committee on outside construction and yard lighting, submitted a complete report which recommended close adherence to the rules of the National Electrical Code and standard specifications of the National Electric Light Association for railroad crossings. This was followed by the report of the committee on illumination which investigated the subject of illumination in classification yards, a completion of the report on day-coach lighting tests and a résumé of recent developments in arc and incandescent lamps.

At the Friday session of the association the report of the committee on yard facilities for charging storage batteries was presented. Following the report of the auditing committee the annual election of officers occurred, and the following were unanimously chosen: President, H. C. Meloy, Lake Shore & Michigan Southern Railroad, Cleveland, Ohio; senior vice-president, E. W. Jansen, Illinois Central Railroad, Chicago; junior vice-president, E. J. Causland, Pennsylvania Lines West, Chicago, and secretary-treasurer, Joseph A. Andreucetti, Chicago & Northwestern Railroad, Chicago. L. B. Hensel, Frisco Lines, St. Louis, Mo., and J. L. Minick, Pennsylvania Railroad, Altoona, Pa., were elected to the executive committee.

At the annual election of the Railway Electric Supply Manufacturers' Association, which holds an exhibit in connection with the Association of Railway Electrical Engineers, the following officers were chosen: President, W. F. Bauer, Edison Storage Battery Company, Chicago; vice-presidents, T. Mount, Consolidated Railway Electrical Lighting & Manufacturing Company, New York, and Fred F. Skeel, Crouse-Hinds Company, Chicago. J. Scribner, General Electric Company, Chicago, was elected secretary, and A. J. Cole, W. A. Fawsett, Edward Wray, T. W. Bender and J. Scribner were elected directors of the association.

Middlesex & Boston Rate Decision

Massachusetts Public Service Commission Authorizes Increased Fares on Middlesex & Boston Street Railway —Résumé of One of the Most Exhaustive Discussions of the Fare Problem Ever Applied to a Suburban Electric Railway System—Enunciation of Broad Policy of Protecting Electric Railway Investments

The Massachusetts Public Service Commission on Oct. 28 handed down a decision of nearly 20,000 words in the Middlesex & Boston Street Railway fare case, which has been pending since July 3. Accounts of the progress of this case have appeared in the news columns of this paper. The company desired to establish a 6-cent fare throughout its system, with an additional charge of 1 cent for every transfer issued. The prevailing fares at the time of the company's notice of the proposed change were 5 cents within Newton and Waltham, with an additional cent for every transfer, except that 6 cents was charged on the old lines of the Newton & Boston Street Railway. The fares on the other lines were 6 cents with free transfer privileges, and the company issued a fifty-ticket book for $2.50, good west of Newton Lower Falls. The average fare received per passenger was 5.44 cents, and the desired increase, if allowed, would have produced an annual increase of about $110,000, or from 10 to 12 per cent upon the company's present passenger revenue of about $950,000. After exhaustive public hearings and investigations by the commission, the company was authorized to establish a uniform fare of 6 cents throughout its territory, but was required to sell nine tickets for 50 cents good between fare limits where the present cash fare is 5 cents and to furnish free transfer privileges at all existing transfer points.

RIGHT TO CHARGE MORE THAN 5 CENTS

A fundamental question presented by the remonstrants was as to a lawful right to charge more than 5 cents for a single fare on certain lines in Newton, Wellesley and elsewhere. It was asserted that a maximum fare of 5 cents had been agreed upon in connection with location grants made by municipal authorities. The commission holds, however, that the public service act (Chap. 784, Acts of 1913) empowers the commission to regulate and prescribe just and reasonable rates notwithstanding any such agreements. (Springfield vs. Springfield Street Railway, 182 Mass., 41; Clinton vs. Worcester Consolidated Street Railway, 199 Mass., 279; Keefe vs. Lexington & Boston Street Railway, 185 Mass., 183; Westwood vs. Dedham & Franklin Street Railway, 209 Mass., 213.) The commission rules "as a matter of law that any alleged conditions or limitations as to fares contained in original grants of locations or growing out of agreements or attempted agreements between municipal authorities and the petitioning railway or any of its antecedent constituent corporations are not valid and controlling as against the rate-making power now vested in this commission by the public service act."

BASIS FOR FAIR RETURN

An extended discussion of value as determined by invested capital rather than by reproduction cost is included in the decision. Some remonstrants contended that the present value of the property used by the company is the only amount upon which it should earn a return. In the board's opinion, however, there is a widespread attempt to misinterpret the real meaning of the United States Supreme Court in opinions dealing with fair value in computing a reasonable return. The refusal of that court to base a return upon securities issued with little or no regard to the value of the property put at the public service, cannot be fairly construed as a ruling that the capitalization laws of Massachusetts and the necessary corollaries therefrom are obnoxious to the Constitution of the United States.

In Massachusetts during recent years reproduction cost as a basis for rate-making has been urged on behalf of certain public utilities, mostly gas companies, that have accumulated out of excess earnings or by unearned increments in land values, large amounts of property not represented by the original capital invested or by the securities issued under the local anti-stock-watering laws. The commission concedes that this cost of reproduction is frequently illuminating and is often the best method of checking up unsatisfactory accounting, particularly that dealing with depreciation. It believes, however, that as a fundamentally controlling principle no theory could work out grosser injustice. In cases of excessive rates, by means of which the companies have accumulated large amounts for capital expenditures, the reproduction cost theory requires the ratepayer to pay a rate that will not only provide for a return upon the capital furnished by the investor but also furnish additional capital and a return thereon. This theory is also grossly unjust to prospective investors, for, if under the most honest and prudent management the plant in building up business depreciates below the fair cost to the investors, the rates must be made adequate to allow a return upon only the reproduction cost of the property in its depreciated condition. This amounts to saying that money lost during the earlier stages of a public service enterprise is irretrievably lost by the stockholders; that if rates have not paid the cost of service, this is the permanent misfortune of the stockholders.

The commission characterizes this theory as being as inexpedient as it is unjust. Public utilities are not finished; they are in process and are constantly calling for new capital in increasing amounts. They must be kept on good trading terms with the investing public or the whole experiment of private ownership and public regulation will fail. It is as necessary to attract capital into public utilities as it is to prevent mismanagement of, or extortion by, such companies. In the long run the rate-paying and the investing publics will be best served if regulation makes as its fundamentally guiding principle the protection of investments honestly and prudently made and wisely managed. Any other theory involves essential injustice, tends to make the development of public utilities a speculation instead of an investment, operates as a premium upon various kinds of fraud and makes every rate case an almost interminable and labyrinthine inquiry into values, with endless conflicts between so-called experts.

Partly owing to the limited scope of the rate-making power possessed by the (former) Railroad Commission, the commission says that there has hitherto been little occasion to deal in detail with the principle that investment and not reproduction cost is in Massachusetts the basis of the relation between the rate-paying public and the investing public. Any other theory, however, will be found to be utterly inconsistent with Massachusetts law. From the time of the granting of the earliest railroad charters in the State, legislation has gone upon the theory that capitalization should be limited to the actual investment and that rates were to be figured on the capital. The Massachusetts public utility code is in striking contrast to the loose and haphazard legislation as to capitalization in many other states, which has frequently resulted in compelling their regulating commissions to resort to reproduction cost as perhaps the least unsafe basis for determining a fair rate.

FINANCIAL CONDITION OF COMPANY

The Middlesex & Boston Street Railway is the result of the consolidation of ten companies. Its capital stock is $1,987,000; its funded debt, $1,983,000, and its floating debt, $1,250,000. The average dividend paid upon the capital stock of the constituent companies from the time of their respective organizations down to the date of consolidation into the Middlesex & Boston Street Railway was 3.09 per cent. The average dividend paid on the stock of the consolidated company is 4.35 per cent. The interest upon the floating debt, amounting, at 6 per cent, to about $70,000 per year, has been a heavy charge against revenue. The company now carries a deficit of more than $265,000, or, including bond discount, of more than $300,000.

PROFITABLE LINES VERSUS UNPROFITABLE LINES

The cities of Newton and Waltham argued that it was unfair for the company serving them to be saddled with a debt growing out of the past unprofitable operation of certain other lines. They asserted that the stockholders of such lines, seeing no reasonable possibility of making earnings on their own lines adequate to insure dividends, obtained through a voluntary association, the Boston Suburban Electric Companies, control of profitable lines. They contended that rates in the more densely populated communities should not be increased above 5 cents, in order to pay interest on debts incurred or operating deficits now alleged to have accrued on the poorer lines. The commission holds, however, that while it would be its duty to refuse to approve a consolidation if it appeared that because of it facilities for travel were to be diminished or fares increased, it is not sound to say that a consolidated company must give exactly the same rates of fare when the traveling facilities are radically increased. The thin lines operate as feeders for the lines in thickly settled communities, thus increasing the traffic on the latter by an unascertainable amount. If the commission should rule that, in determining a just and reasonable rate upon any short line where traffic is dense, it must recreate the conditions which might have existed on that short line if it had remained in the ownership and control of the single company formerly owning it, the result would be inextricable confusion and a sort of chaotic adoption of the zone system found in many European cities.

The commission rules that the Middlesex & Boston Street Railway must be dealt with as a single company, but the prudence of its investments is to be considered in fixing the return. While the commission feels that it would not be in the public interest to rule that any of the capital invested in the creation of any of these lines was so recklessly and imprudently invested as now to warrant the adoption of a policy likely to result in abandoning or tearing up some of them, it believes that undoubtedly in more optimistic days street railways were built in Massachusetts upon which a full return cannot now be earned without charging rates intrinsically unfair and perhaps destructive to traffic. Public interest and public sentiment require, however, that, within all reasonable limits, such lines should be conserved, not only for a probable increase in population, but for a probable increased handling of express, light freight and farm produce. There are reasonable limits to the arguable discrimination growing out of requiring patrons of street railway lines in the thickly settled communities to pay more than the cost of their short carriage in order to contribute to losses incurred in the longer hauls through the thinly settled sections. But the "short riders" of to-day may be the "long riders" of to-morrow. Moreover, population centers profit in many indirect ways from street railway lines ramifying into rural sections. A sound transportation policy requires consideration of the relations between transportation facilities and living conditions. The commonwealth, which expends the taxpayers' money in the construction of good roads all over Cape Cod and through the Berkshires, would not be content with a policy which promoted the abandonment and destruction of existing street railway facilities in Eastern Massachusetts.

CAPITALIZING PROPERTY PURCHASED FROM RECEIVER

One of the components of the Middlesex & Boston company is the former South Middlesex Street Railway, which was purchased at a receiver's sale in 1907. In accordance with the statute (Acts of 1906, Chap. 483, Part 3), that part of the company's debt growing out of its attempt to purchase the South Middlesex company for $125,000 in excess of the latter's replacement cost, is illegal and must be cancelled. (Commissioner White dissents from this view, and the decision says the company can test the impending order of cancellation by appeal to the Supreme Judicial Court.)

RELATIONS WITH HOLDING COMPANY

Discussing the relations of the road with the Boston Suburban Electric Companies, the board finds that the control of a street railway by a holding company, which loans large sums to the former at a substantial profit to the latter; which controlled a company selling power to the railway (not the Edison Electric Illuminating Company of Boston referred to elsewhere), and also controls a park company to which large annual payments are made by the street railway, is obnoxious to sound principles of corporation management and confusing to a proper system of regulation. Such interlocking management calls in question the validity and advantage to the street railway of all contracts growing out of the common control. As regards the park, the board looks with displeasure upon investments of electric railways off their lines, although favoring within narrow limits expenditures for advertising of direct probable return.

RATES PAID FOR BORROWED MONEY

Since the consolidation, the largest single function performed by the holding company has been that of loaning to the railway more than $1,000,000 at an average rate of 6 per cent. While the propriety of this rate is said to be not fully sustained, the commission concedes that the railway, without having its credit buttressed by this pooling device of the stock, might not have been able to procure this sum in the open market at a substantially lower rate. In the last six years the holding company has furnished the railway about $3,308,109 at an average rate of 4.59 per cent.

COST PER MILE OF SINGLE TRACK

The cost per mile of single track, compared with the average cost for fifty-two other Massachusetts street railways exclusive of the Boston Elevated and the West End Street Railway, is:

	Middlesex & Boston	Other Roads
Construction	$23,440	$23,098
Equipment	9,867	7,732
Other permanent property	7,678	8,254
Total cost per mile	$40,985	$39,084

This showing, the board finds, is on the whole favorable to the company.

COST OF POWER

The commission concludes that the company has not fully sustained the burden of showing that its contract made with the Boston Edison Company for power, contemporaneously with the sale by the holding company to the Edison company of the plant at Waltham formerly furnishing a considerable portion of the power used by the railway, was the best available arrangement for the latter. The railway receives energy from the Edison company on a ten-year contract at the rate of about 1.75 cents per kw-hr., present average. The company is ninth in a list of Massachusetts roads in its power cost per car-mile, at 4.76 cents, as compared with minima of 2.96 cents for the Bay State Street Railway and 2.26 cents for the Boston Elevated Railway. Maintenance of power equipment is included in these figures. The commission is of the opinion that the power cost is high, although probably not more than $12,000 per year. The commission holds that the company cannot be permitted to buy its power at a high price and to keep, permanently, unused power plants of its own. Within a reasonable time it should equip and use its own plants or sell the unused property and apply the proceeds to a diminution of the obsolescence. The commission recognizes the tendency toward tidewater generating stations of large capacity, but suggests that the large power business of the Edison company be regulated as to price by the Gas & Electric Light Commission. It also points out the desirability of more competition in this field, touching upon the possible advantageous supply of electricity from railways with plants on tidewater to interior companies.

DEPRECIATION

The commission points out that few Massachusetts companies have of recent years charged enough to operating expenses to cover real depreciation. In this particular case, an analysis of the company's operations, allowing 20 per cent of gross revenue to cover maintainence of way, structures and equipment from 1908 to 1914, shows that the company has undercharged operating expense by $277,059. This indicates that the net revenue has fallen far short of being adequate to keep intact the fair cost of the property put by the company into the public service.

SERVICE AT LESS THAN COST

Considering the low dividends paid from the time of organization and the above lack of proper depreciation charges, the commission finds that the rate-paying public has been receiving service at substantially less than cost. At no time have the rates charged been adequate to meet the fair cost of the service, and as between investors and patrons, the patrons have had much the better of the bargain. Regarding the payment of even moderate dividends without taking care of depreciation, the commission says that there is a great practical difference between the payment of dividends averaging 4.35 per cent (no more, perhaps even less, than an investment rate on money, which tends to keep the corporation in some sort of credit), and the payment of dividends so in excess of the investment rate as to put the stock on a speculative basis.

FINAL TEST OF COMPANY'S FINANCES

From the charges against income the commission deducted the annual interest on the $125,000 excess replacement cost of the South Middlesex Street Railway; assumed that the deficits of the constituent companies were cancelled at the time of consolidation; deducted all payments to the Norumbega Park Company; reckoned 6 per cent as the annual interest on the floating debt; assumed that 20 per cent of the gross revenue had been expended yearly to meet the cost of maintenance and depreciation, and assumed that the company is entitled to an annual dividend of 6 per cent. On this basis there would still be an annual operating deficit of more than $34,500. Even if the estimated excess cost of power of $12,000 per year were deducted, the annual revenues would still be insufficient by more than $22,500 to pay 6 per cent on the stock. The application of the present arbitrated wage schedule would increase this operating deficit to a total of more than $67,000 per year.

INFLUENCE OF WAGE ARBITRATION

The immediate occasion for the company's application is increased operating expense, due to increased labor cost resulting from the award of the board of arbitration dated June 22, 1914. This award requires the company to pay for labor during the coming year about $37,000 more than for the same labor under the old rates, besides perhaps $8,000 more due to change of hours, etc. The award also provided for the payment of about $30,000 of retroactive wages. The commission accepts the award as doing no more than justice to the employees, and doubts not that the patrons of the company will likewise accept it and the consequent increased cost of transportation as a proper charge.

CONCLUSIONS LEADING TO RATE INCREASE

The commission concludes that without an increase of fares, earnings adequate for the payment of any dividend cannot reasonably be expected. Both justice and expediency require that capital as well as labor employed in the public service should have its fair living wage. As a broad proposition, it is in the public interest that railway companies should earn and pay such dividends as to keep their stock at or a little above par. Under present financial conditions nothing less than a dividend of 5 or 6 per cent would bring a carrier's stock, otherwise reasonably sound, up to a par value.

The commission states that the petitioner's request for a change of fares would, if allowed, give a probable increased revenue of about $110,000 a year. On all the facts, a schedule of fares showing an increase of probably not more than two-thirds of that amount is in the public interest and required in justice to the company. It is not unreasonable to suppose that some advance over original fares might now be necessary even upon the better paying lines if these had continued to be separately operated. While some increase may even be justified upon the lines where a 5-cent far is now charged, yet these lines should continue to enjoy a somewhat more favorable rate than the remainder of the system.

The commission believes that its award, as outlined in the opening paragraph of this abstract, is just and equitable as between the different communities involved, and will cause as little hardship to patrons as any scheme that can be devised to provide the additional revenue to which the company is entitled. The schedule approved, with rigid economy—which includes the purchase of power on more advantageous terms—will enable the company to obtain sufficient revenue to maintain its property in safe and sound condition, expending for maintenance and renewals, until some general basis for dealing with depreciation is ordered or indicated by the commission, substantially 20 per cent of its gross revenue, and also to provide for the paying of moderate dividends.

European Public Utilities

Effect of Present War on European Capital and Engineering —British and German Tramway Statistics

W. J. Clark, of the General Electric Company, presented an address on European public utility conditions at the Public Service Railway section of the American Electric Railway Association at Newark, Oct. 29. He said that he would have to describe the conditions before the war, as no one can foretell the radical changes which must come to both the engineering profession and public utilities as a result of the destruction now going on in Europe.

Contrary to the general supposition, a great portion of the European public utilities, except the government-owned railroads, telegraph and telephone systems, are controlled by European international capital, instead of being owned within the countries where such projects are located. This plan, which has also been followed the world over, explains to a large extent the dominating position of the European countries in foregn trade. It is impossible even to approximate the total of such European investments, but recently the earnings from those of the United Kingdom have been estimated by economists to be about $600,000,000, while the combined similar investments of Germany and France have been estimated at approximately the same amount. Looking to the future, it is but logical to suppose that European countries must dispose of many such investments to secure the necessary capital to replace that which is being destroyed in Europe, while the bonds which have hitherto bound European international capital together have doubtless been severed.

The disastrous future effects of the present war will be marked upon European engineers and engineering, because probably more than 75 per cent of all of the active engineers in Europe are now in military service, and this includes, of course, the flower of the profession. The casualties in the engineering regiments have been greater than in other branches of service. In one regiment which went to the front over 1700 strong, there are now less than 180, and in another which mobilized at 2200 less than 350 remain. If the present terrible condition continues, seemingly before the European engineering profession can regain its former numerical strength and efficiency, another generation must be so educated and acquire its practical engineering experience.

STATISTICS ON EUROPEAN TRAMWAY ENTERPRISES

Statistics on European tramway enterprises as existing before the war are difficult to compile and compare. They differ greatly in character and extent, and in no two countries have they been compiled on the same basis. Heretofore, Belgium has been the headquarters for a number of the public utility holding companies because of its supposed neutrality.

A comparison of the wages paid on tramways in America and Great Britain show that the British wages are about half of the wages paid in this country. From this it is obvious that if American rates were paid in Britain its tramways could not meet their fixed charges. On the other hand, if British wages of labor prevailed here, our street railways could be operated at about 30 per cent of their gross receipts or other equally surprising things could be accomplished. In spite of this fact the roads as a whole are not a commercial success. The total capital investment in the British and municipally-owned tramways is $246,493,034, and after the payment of interest and fixed charges, the deficit from operation last year was about $660,000. This unfavorable showing is made greater by the fact that less than 2 per cent on the investment was charged in operating expenses to depreciation and renewal funds.

According to the British Municipal Year Book of 1914, as regards England and Wales: "In 1912-1913, the sums transferred in aid of rates from the accounts of electricity and gas supply undertakings, harbors, docks, piers, canals and quays, tramways, light railways and water works, was £41,000. The total of the sums transferred from rates to meet deficiencies in the accounts of such undertakings was £151,000.

GERMAN STATISTICS

The conditions in Germany are described by Dr. Richard Passow as follows: "Out of thirty-six municipal street railways in 1908, nine were operating without profit. Further, twelve showed that some financial assistance was required from the municipality, partly due to the extensive number of employees and administrators appointed by the state authorities."

Quite complete German tramway statistics are available, and the following is a translation of the summaries shown by them.

STATISTICS ON STREET RAILWAYS IN GERMANY—1912

	Company Plants	Municipal Plants	Total Municipal and Company
Length of track (kilometers):			
On street	3,113	1,785	4,898
On private right-of-way	368	156	524
Total	3,481	1,941	5,422
Number of employees	30,470	17,278	47,748
Rolling Stock:			
Steam locomotives	59	5a	64
Electric locomotives	25	22	47
Number of passenger cars	13,331	8,650	21,981
Total all cars	15,284	9,199	24,483
Total seating and standing space provided in passenger cars	457,821	310,644	768,465
Average carrying capacity per car	......	......	35
Passenger car kilometers	433,831,507	306,188,099	740,019,606
Number of passengers carried	1,526,153,644	1,203,072,641	2,729,226,285
Cost of erection (marks)	768,590,580	394,501,728	1,163,092,308
Invested capital (marks):			
From government	11,371,803	1,694,600	13,066,403
From province	3,653,467	10,501,250	14,154,717
From county	16,625,237	9,538,312	26,163,549
From parties interested	28,641,396	352,912,372	381,553,668
From other sources	733,998,230	50,807,694	784,805,924
Total invested capital	794,290,133	425,454,228	1,219,744,260
Passenger receipts (marks)	162,114,210	130,054,929	292,169,139
Freight receipts (marks) Postal receipts (marks)	1,523,784	162,638	1,686,422
All other receipts from railway service	7,070,574	2,001,924	9,072,498
Summary of receipts	170,708,568	132,219,691	302,928,259
Summary of expenditures	106,483,296	75,008,146	181,491,442
Allowance for depreciation	8,409,636	6,634,409	15,044,045

NOTE: "a," gas locomotives.

The following is apparent from these statistics:

About 36 per cent of the trackage is government owned. The total trackage is approximately 14 per cent of the similar length of line in the United States. The number of cars is equivalent to 26 per cent of those in this country, but the average carrying capacity of the German cars is but thirty-five, whereas such average in this country is about double that figure.

The number of passengers carried is equivalent to 22.5 per cent of those carried in the United States. The total passenger receipts are the equivalent of $73,042,285, equal to 14.7 per cent of those in this country. The total operating revenue is equivalent to $75,932,065, or 13.5 per cent, of the similar item in the United States.

Operating expenses are almost exactly 60 per cent of operating revenues. The passenger car-miles run are approximately 462,515,000, equivalent to 24.5 per cent of those run in America.

Officials of the Louisville (Ky.) Railway were hosts recently to the members of the Louisville Engineers' & Architects' Club at an inspection of the new shops and a new power station of the company, which have been put into operation.

COMMUNICATIONS

Operation by Signals Preferable to Train-Order System

SCRANTON & BINGHAMTON RAILROAD

SCRANTON, PA., Nov. 4, 1914.

To the Editors:

In response to your request for an explanation of the points raised in Mr. Handshy's communication (published in last week's issue) I might say that the duties of trainmen, under our system of operating by signals alone, have been very much simplified. The elimination of the complications of the train-order system, with its tax upon the memory and its necessity for experience in interpretation, has, to all intents and purposes, reduced our procedure to that figuratively outlined in your editorial of Oct. 3.

The question as to what is done when a signal failure occurs may best be answered by quoting from our standard book of signal rules as follows: "When a train is stopped by an automatic signal that is evidently out of order, the motorman, ... after waiting five minutes, will proceed at a speed not to exceed 8 m. p. h., being prepared to stop within one-half his range of vision until he has reached the next proceed signal, expecting to find a train, open switch, broken rail or other obstruction on the block. At curves, or during fog or other weather conditions that obscure the view, the conductor must go ahead of the train far enough in advance to stop, within a safe distance, any opposing train."

You will understand, of course, that the direction indicator, which is located some 200 ft. in advance of each siding home signal, will not give its proceed indication in case an opposing train has entered the block in advance of the defective signal. Therefore, the train which proceeds under the above rule is not confronted with the possibility of advancing against a high-speed opposing movement unless both the signal and the direction indicator fail at the same time—a contingency that is so remote as to be a practical impossibility.

The possibility of false clear indications, to which Mr. Handshy refers, was, of course, thoroughly investigated before our signal system was adopted, and we consider that the combination of intermediate signals and direction indicators which has been installed constitutes as perfect a check against head-on collisions due to false clear indications as can well be conceived in the practical art of automatic signaling.

As a matter of fact, we have had no clear failure as yet, although it may be that we shall have one some day. However, clear failures in general are of such rare occurrence as to be of the order of one per 1,000,000 movements, and, on at least one line equipped with Union Switch & Signal Company's apparatus (as is also the Scranton & Binghamton Railroad) clear failures have happened only once in about 60,000,000 movements. Consequently, they cease absolutely to be worthy of special consideration when, to be dangerous, they must occur in conjunction with abnormal failures of several pieces of apparatus at exactly the same time. In addition, since it is necessary to have cars in certain narrowly defined positions before a collision can occur, even when there is a clear failure of a signal as well as all of the checks upon its operation, the odds against the contingency rise practically to infinity. To be perfectly frank, I consider the signal system on the Scranton & Binghamton to have safeguards and checks which are considerably more effective in practice against dangerous false clear indications than would be the check provided by train orders.

R. W. DAY, General Manager.

Methods of Calculating Depreciation

PACIFIC GAS AND ELECTRIC COMPANY

SAN FRANCISCO, CAL., Oct. 21, 1914.

To the Editors:

I have read with much interest the article on "Depreciation" by Ralph U. Fitting, published in the ELECTRIC RAILWAY JOURNAL of Sept. 26, and believe that Mr. Fitting's very complete presentation of various classes of depreciation and the methods of computing allowances to meet depreciation will assist very materially to a better understanding of this very complex question.

In following the discussions of this subject that have appeared from time to time, and in talking to many who are interested in the financing and operating of public utilities, it has seemed to me that there is a very evident tendency to take the depreciation question too seriously, that the theory of depreciation is being allowed to cloud the issue, and that we are losing sight of some very practical and commonsense facts.

We have at the present time two separate, although related, problems involving depreciation:

1. Accrued depreciation and its effect on value.
2. Deduction from revenue to take care of property retired from service.

In discussing the first problem we find many arguments, theories and illustrations used both pro and con as to how the accrued depreciation should be considered in valuing property and, as far as I have been able to analyze the attitude of mind of those presenting the different sides of the question, the real difference lies in a fundamentally different conception of depreciation. I believe that, expressed very generally and briefly, these conceptions are:

(*a*) Depreciation is a part of the value of the property which is being taken away from the property, just as the coal taken out of a coal mine is a part of the value of the mine being taken away.

(*b*) Depreciation is nothing more nor less than an accounting method of equalizing the cost of replacing and retiring property over a long period of time in order to avoid distorting the operation and maintenance accounts in any relatively short period.

The first theory loses sight of the fact that a public utility property is not a simple structure that is here to-day and gone to-morrow, but is a complex structure that is permanent in its function and existence.

The second theory holds that as long as an existing property is giving the equivalent in service and efficiency of a new property there is no depreciation in value beyond some possible deferred maintenance. It must, of course, be admitted that there are some cases where this will not hold true, but for a normal healthy public utility I believe this theory to be the correct one.

The computing of the proper amount to be set aside, out of earnings, to meet the retirements of property from time to time is, as Mr. Fitting points out, difficult, but I cannot agree with his conclusions that the percentage of gross earnings method is the best. It seems to me self-evident that while we may perhaps for some particular property hit upon a percentage of the gross earnings that will fill the requirements, this same percentage in some other property would not be satisfactory. The useful life of the different parts of a property is a function of the make-up of those parts and has nothing to do with the earnings. We may not now be able to estimate exactly the proper percentage of the value of the various classes of property to put aside, but it should be remembered that a public utility is made up of many classes of property, and while we may overestimate the percentage on one class we in all probability will underestimate the percentage on other classes. It is only by experience that we shall be able to determine the proper percentage, and if we continue on an arbitrary method based on earnings we shall never be any wiser than we are now. On the other hand if we base the annual allowance on percentages of value and use every effort to compile data for checking and revising these percentages, we shall be able, as time goes on, to determine from actual experience with a greater degree of accuracy what these percentages should be. JOHN A. BRITTON,

Vice-President and General Manager.

Insert Special Work Failures

OMAHA & COUNCIL BLUFFS STREET RAILWAY

OMAHA, NEB., Oct. 17, 1914.

To the Editors:

Having read carefully the interesting articles in your issues of Sept. 19 and 26, I state below a few observations we have made in the construction and maintenance of special work of the hard-center type.

Most of our experience has been with the 7-in. type, made up of iron-bound 107-lb. and 108-lb. girder guard sections. We also have some of 97-lb. section, and all are fitted with manganese centers of various types. About two years ago we adopted the practice of using 6-in. x 8-in. sawed white-oak timbers of different lengths, as a support for all special work in paved streets. On the special work blueprint we locate the ties most advantageously and use different lengths as needed to give the steel proper bearing on the foundation. This facilitates tamping as compared with the old practice of weaving a number of 7-ft. ties throughout the layout. Such practice sometimes made it impossible to tamp the ties solid at points where proper tamping was absolutely essential. Moreover, a much stiffer foundation results at only a slight increase in cost, when special ties are used, and tamping is more easily accomplished.

Our sub-grade is generally of hard yellow clay, and with a 6-in. bed of well-tamped crushed rock under our ties, a very uniform bearing is obtained. Our drainage is good as the streets all have considerable grade. Wherever the sub-soil is of poor quality, as, for instance, where fills have been made, we use a combination construction consisting of a 6-in. concrete slab on which we surface the switch ties with 2 in. of stone screenings.

In handling iron-bound special work we use an electric crane and usually make the installation at night. We stake off the work accurately so that the steel may be installed, spiked and bolted to line without necessitating the strenuous use of screw jacks and drift pins to obtain alignment after the layout is in place. The use of screw jacks and drift pins in pushing and drawing frogs to line is, no doubt, very injurious to iron-bound construction. We find it necessary, however, to use jacks occasionally in lining, but this is done under very careful supervision. Drift pins must be used also to bring joints together, but only for a slight movement of the frog with spikes loosened. This does not entail harmful results. We find it important, when bolting up the splices, to have all joints drawn tight. After the installation is complete the surfaces of all joints are ground smooth. We believe grinding will add to the life of the joints and in turn to the special work as a whole.

Our loose-center trouble is confined almost wholly to 90-deg. crossings. We have had some trouble with the centers in curved crossings after having been in use several years, but the most serious trouble exists with the 90-deg. type of crossing, of which we have a great many. Present-day cars, which weigh from 18 tons to 22 tons empty, cross over flangeways in center plates 1⅜ in. wide every two or four minutes, exert considerable lateral thrust on plates and make the problem of special work construction and installation increasingly difficult. We have found on 90-deg. crossings that an entire spelter bed for the plate soon settles and excessive pounding results which ultimately breaks down the foundation. Some of our centers are set on lead slugs before pouring the spelter. These do not stay to surface as well as those with either a partially machined bearing or those set on steel shims before pouring. We also find that unless a hard-center plate has a tight fit at all four points where it joins the arms, it will not stay tight for any reasonable length of time.

Another serious condition to meet, which affects our hard-center maintenance, and is mentioned in the article, is the thin-flanged steel wheel. Our cars are all of the single-end type, the operation of which tends to cause unusual wear of wheel flanges. A continuous crowding of one rail (usually the inside) results in one wheel flange wearing thin, while the opposite wheel develops what might be called a double flange. When they strike a hard center the wheels must be pulled over at the flangeway. This throws a lateral strain which, on any hard center of present design, must be resisted by the spelter-filled edge. We have noticed that the manufacturers do not always carefully provide for such a condition. In grinding flangeways, care should be exercised to make the approach to the narrow throat of the hard center as easy a transition as possible, even though it might mean an increase in the size of the manganese plate.

Rail arms in iron-bound 90-deg. construction should not be longer than 4 ft. We find in some cases that longer arms up to 6 ft. or 7 ft. have been provided in the past to meet existing joints. In these the compromise joint weakens sooner or later, and if this is not detected at the time of slight movement, an excessive bending moment will occur at the casting which it cannot resist, and a rupture occurs. In order to reduce difficulties to a minimum we employ special repairmen on joints and special work. As soon as a piece appears to be loose on its foundation it is promptly resurfaced. We endeavor to guard against any loose joints in special work and carefully inspect and repair it as soon as they are detected. A loose compromise or ordinary joint will allow a pumping action which causes the arms to cut into the tie and within a short time the arm is loose in the casting.

The comparatively new process of using the electric welder for building up special work intersections, seems to offer a most promising field for the development of a solution for hard-center troubles. The perfection of the qualities of the steel which can be welded to intersections will bring a demand for the use of the one which will successfully amalgamate with manganese centers. Perhaps the frogs themselves can be cast of some alloy other than manganese steel, to which the electric welding process may be applied satisfactorily. With this developed, the flange bearings and intersections could be readily kept in proper condition, thereby satisfying the public demand for less noise at intersections, and at the same time conserving the life of rolling stock. F. H. FINDLEY,

Superintendent Track and Roadway.

The Daily Report of the Convention

THE SOUTHWESTERN ELECTRICAL & GAS ASSOCIATION
DALLAS, TEX., Oct. 30, 1914.

To the Editors:

I have again been in prompt receipt of your convention daily issues and again wish to express to you my appreciation of these. The comfort, convenience and pleasure of having the daily proceedings of the convention "hot off the bat" at this long distance away should certainly be appreciated by those who are compelled to be absent from the convention, and it should also certainly be appreciated by those at the convention nearly as much as by the absentees.

I did not notice that the various associations gave you a vote of thanks for your enterprise in this matter, but they certainly should have done so and made it a "rising vote"! H. S. COOPER, Secretary.

Public Relations Number

Newspaper Comments on Our Convention Issue—General Approval Expressed

The two score of articles devoted to electric railway progress and improvement and the general subject of public relations, published in the convention number of the ELECTRIC RAILWAY JOURNAL, issued on Oct. 10 in connection with the annual convention of the American Electric Railway Association, were well received in the daily newspaper field, as shown by both reprints of many of the articles and editorial comment on them.

The articles in this number that were drawn upon for reprint material varied widely as to subject matter discussed, and the excerpts published ranged from single paragraphs in a few instances to solid columns in such newspapers and other publications as the Philadelphia *Public Ledger*, Chicago *Daily Tribune*, Boston *Evening Transcript*, *Wall Street Journal*, Rochester *Democrat*, Boston *Christian Science Monitor*, Grand Rapids *News*, Salt Lake City *Tribune*, *The Times Annalist*, Boston *Commercial* and many others. A few of the articles that received the greatest newspaper publicity were the following: "Proposed Co-operative Arrangement at Philadelphia," by A. Merritt Taylor; "Financial Relations Between Cities and Utilities," by Bion J. Arnold; "Electric Railroading in Utah," by Simon Bamberger; "Winning the Confidence of the Public," by Robert M. Searle; "Is Publicity a Cure-All?" by A. W. Warnock; "The Importance of Good Public Relations," by Theodore P. Shonts; "Improvement of Relations Between Electric Railways and Employees," by Charles W. Eliot; "Public Utility Regulation—A Cloud on the Horizon," by H. H. Crowell; "Five Years' Development of the American Electric Railway," by Frank R. Ford; "The Electric Railway and the Farmer," by John R. Graham; "Aspects of Rush-Hour Service," by E. C. Foster; "Local versus State Regulation," by Richard McCulloch, and "Co-operation in Transit Contracts," by Timothy S. Williams.

One of the most interesting features in connection with such newspaper publicity was the geographical distance which often separated the author of the article and the newspaper in question, showing that the ideas presented and not merely the personality of the author led to the abstracting of the paper. For example, portions of the paper of Richard McCulloch (St. Louis, Mo.) were published in New York; by A. W. Warnock (Minneapolis, Minn.) in Manchester, N. H.; by Jesse W. Lilienthal (San Francisco, Cal.) in Butte, Mont.; by Robert M. Searle (Rochester, N. Y.) in Camden, N. J., and Springfield, Ohio.; by E. C. Foster (Manchester, N. H.) in Paterson, N. J., and by Frank R. Ford (New York, N. Y.) in Boston, Mass. The remarks of Dr. Eliot (Cambridge, Mass.) were quoted in New York, Freeport, Me.; Newark, N. J., and Chicago, Ill., and other cities, while the article by John R. Graham (Bangor, Me.) reached Chattanooga, Tenn.

As examples of the editorial comment aroused by the above-mentioned and other articles, the following three have been picked at random. Referring to Dr. Eliot's article, the Chicago *Tribune* says:

"Some of these reforms are in actual operation in European countries. Some have been tried in this country with success. The combining of all of these measures into one system affecting and modifying the wage relations of to-day to the extent to which Dr. Eliot would have them modified, has not yet, however, been attempted. It may be some time before the American people are ready to consider Dr. Eliot's program. To the extent, however, that his suggestions stimulate serious thought about present industrial conditions, they are of immediate value and helpfulness."

The Brooklyn (N. Y.) *Daily Times* comments on Mr. Williams' article in part as follows:

"As Colonel Williams well points out, the danger exists and will continue to exist, that the commission in its desire to please local interests or to gain political advantage may lose sight of the great public function with which it is entrusted. For it must not be forgotten that, although somewhat crudely, we have, at least in an approximate sense, taken municipal affairs out of politics, while no such change has been effected in state affairs, and it is questionable if it ever will or should be.

"When a tremendous undertaking, such as the completion of our subway system, is discussed as rationally and intelligently as by Mr. Williams, and when the principles in such a transaction are so transparently clear and candid, there can be no doubt that we have reached in our own dealings with large transit problems an era and a condition that would have been pronounced the millennium a few years ago."

Concerning Mr. Taylor's outline of the Philadelphia program, the *Public Ledger* of that city says:

"Director Taylor's illuminating summary of the rapid transit program revives interest in the momentous proposition and serves to stimulate fresh interest in the approaching loan election. No other measure of city development has ever been promulgated which will propel Philadelphia forward to the same extent. The more the plan is studied the more feasible it appears, safeguarding well the public's interest and justly caring for the rights of the transit company."

Association of Technical Associations' Secretaries

As announced in the issue of the ELECTRIC RAILWAY JOURNAL for Oct. 31 a meeting of technical association secretaries was held in New York on that date, and an association was formally launched. The temporary organization will continue until the meeting which is to be held on some date between Jan. 1 and March 1, at which time the nominating committee will report a list of suitable nominations for the officers provided for in the adopted by-laws. The American Electric Railway Association was represented informally at the organization meeting by C. W. Stocks, statistician, and H. H. Norris, ELECTRIC RAILWAY JOURNAL, who attended in place of Secretary E. B. Burritt. An important feature of the work of the new association will be the distribution of information regarding convention dates and places of technical societies. It is expected also that the getting together of representatives of the societies will be helpful in preventing duplication of work and in enabling the secretaries to benefit by each other's experiences.

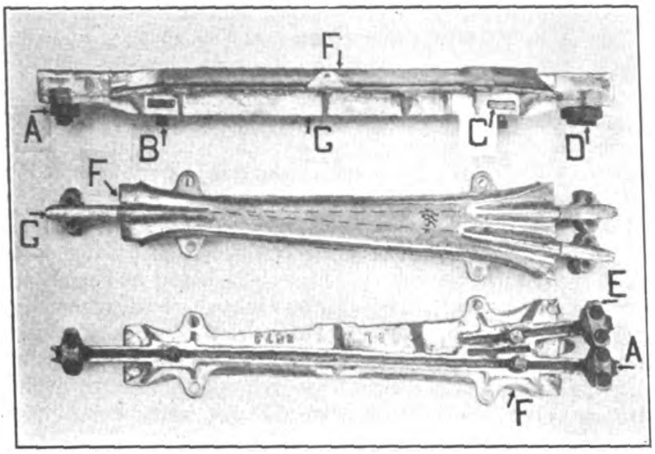
A Method for Locating the Correct Position of Overhead Frogs

BY ROBERT D. DIXON, MAINS SUPERINTENDENT NEW SOUTH WALES GOVERNMENT TRAMWAYS, SYDNEY, AUSTRALIA

Of the various fittings used on overhead construction for tramways and street railways, none has been the cause of more trouble than the frog. From the earliest days, when the angle between the tongue containing the branch trolley wire and the tongue on the main line was 45 deg. down to the present time when this angle has been reduced to about 6 deg., the frog has been a fruitful source of annoyance. In the infancy of electric traction the pole, more frequently than not, left the trolley wire when taking the turnout. Even when the car took the frog at a snail's pace, the conductor had to hold the trolley rope, so that the pole might be placed on the wire after refusing to travel in the required direction.

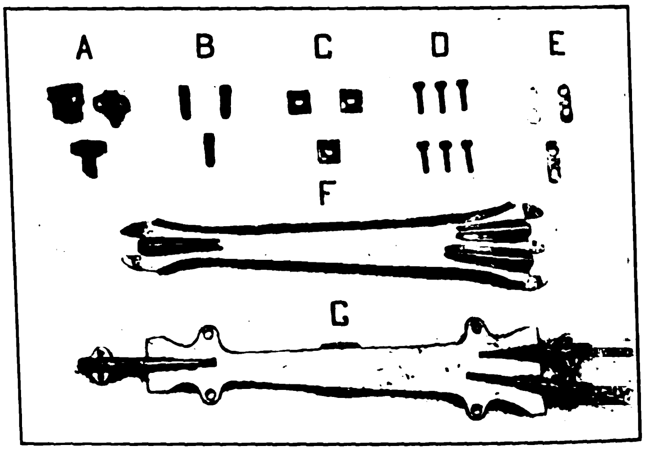


SYDNEY TRAMWAYS—ASSEMBLY OF FROG

As it became necessary to increase the speed of cars at junctions, so the limitations of the frog, as first designed, became more exasperating. The angle between the tongues was gradually reduced, with a corresponding decrease in the number of poles leaving the line. When the angle had been reduced to 9 deg. the length was greatly increased, and the weight of the frogs, which were of gunmetal, became excessive. In order to reduce this angle still further the frogs were made of an aluminum alloy, but the wearing parts were protected with thin steel plates.

These frogs gave very satisfactory results, but, together with all other previous designs, they had a serious disadvantage, as the whole frog required removal when the tongues and sides had become worn out. It was, therefore, necessary to evolve a new design in which the body, or backing, of the frog is made of an aluminum alloy (aluminum 98 per cent, copper 2 per cent), and a pressed-steel plate comprising the bottom, flanges and tongues is attached to the aluminum body. All the wearing parts are thus made of steel. When the frog requires renewal all that is necessary is to remove the old pressed-steel plate and attach a new one. The saving of time and money, as well as the reduction of interference with traffic, with this type of frog is of the greatest importance. It has also the advantage that when the frog is once correctly set the renewal of the steel plate does not in any way affect its position.

As far as the author can learn, a satisfactory method for accurately locating the correct positions for leading frogs has not yet been developed elsewhere. It has been seriously stated that the best method of locating frogs is to run a car on the branch line while leaving the trolley wheel on the wire over the straight track, the point where the wheel leaves the straight wire determining the position for the frog. Another method is given as the center of the triangle which is formed by the width of track at the points as its base, the apex being the point where the outer rail crosses the straight. Such methods naturally do not give satisfactory results, especially in cases where the car travels at high speeds. The method adopted on the Sydney, New South Wales, system has for some years been in operation with most satisfactory results, and it is a very rare occurrence for a pole to leave the wire at a frog, even when the speeds are excessive.



PARTS

Part	Weight
A—Cast-iron tongues	Weight 3 lb.
B—Set screws	
C—Nuts	
D—Bolts	
E—Locking strips	
F—Stamped steel plate	Weight 2 lb.
G—Aluminum body	Weight 5 lb.
Total weight	10 lb.

SYDNEY TRAMWAYS—DETAILS OF FROG

Some years ago special measurements were taken of the radius of track, superelevation of both straight and branch roads, and the exact position of the frog (9 deg.) in cases where it was known that frogs had given very good results. From these measurements it was calculated that the angle made by the plane of the trolley wheel with the trolley wire was in the vicinity of 15 deg., with one particular type of car. When the new type of frog ($5\frac{1}{2}$ deg.) was adopted, it was decided that its position should be such that the angle made by the plane of the trolley wire with the plane of the trolley wheel should be 11 deg.

The method of determining the position for the frog is as follows: Starting from the switch points, the superelevation (if any) of the straight track is measured at intervals of 5 ft. If the trolley wire be 19 ft. above rail level, and track gage 4 ft. $8\frac{1}{2}$ in., the superelevation obtained must be multiplied by $\frac{19\text{ ft. }0\text{ in.}}{4\text{ ft. }8\frac{1}{2}\text{ in.}} = 4.$ This would then give the theoretical offset in which the trolley wire should be placed on the straight track. However, as trolley wheels are not invariably placed in the same plane as the trolley pole, an additional offset of 2 in. is allowed, so that when a car is taking the straight track the trolley wheel tends to hug the guiding flange of the frog. When making allowance for superelevation it must be borne in mind that the car wheels are in advance of the trolley wheel, and that the superelevation of the track at the car wheels affects the position of the trolley wheel at its point of contact with the wire, which, in the case of a four-wheeled truck, would be about 11 ft. to the rear of a point vertically over the truck center.

Again, starting from the points, measure the superelevation on the turnout at intervals of 5 ft. Owing to the pivotal point of the trolley pole on the car roof—more especially on double-truck cars with the trolley pole in the center of the car—not being vertically above the center of the track, measurements must be taken to ascertain this offset. The easiest method is as follows:

The distance between truck centers being known—say, 22 ft.—the tape is run out to 22 ft. and placed as a cord across the arc made by the rail, and the versine measured, the tape being moved forward 5 ft. after each measurement is taken. To these figures must be added the offset of the pivotal point of the trolley pole due to superelevation. The superelevation of the track is, in this instance, not multiplied by 4, as the height of the pivotal point is not 19 ft. 0 in. above the track, but, say, 11 ft. The superelevation must, therefore, be multiplied by $\frac{11\text{ ft. }0\text{ in.}}{4\text{ ft. }8\frac{1}{2}\text{ in.}}$, or 2.34. These measurements thus give the curve traced out by the pivotal point of the trolley pole as the car takes the curve. The horizontal projection of the trolley pole in use on the Sydney system is about 11.4 ft. with a trolley wire height of 19 ft., and it can readily be seen by reference to the diagram that all that is now necessary is to lay down on the track the position of the trolley wire on the straight track and the position of the curve traced out by the pivotal point of the trolley pole, fix the point where the distance between them is 2.19 ft.—which is the base of an isosceles triangle having for its two sides the horizontal projection of the trolley pole (11.4 ft.) the angle included between them being 11 deg.—then measure 11.4 ft. back toward the switch points, which gives the position of the frog.

The explanation of the method takes longer to write than does the whole process of the location of the frog on the ground. When the engineer has become proficient in the work of setting out frogs, the operation should not take more than a few minutes.

Owing to local conditions the superelevation is occasionally the reverse of that ordinarily experienced, and the engineer must make allowances accordingly.

The most difficult frog to set in its correct position is that at the junction of two curves which are converging. (See diagram.) In this case the straight tongues are set for the track having the curvature of larger radius, and the branch tongue for that of smaller radius, The position of the frog on the curve of larger radius is on the trolley wire curve, as shown in the writer's article, published in this journal on May 7 last, except that the additional offset of 2 in. is given, as before mentioned, for the purpose of forcing the trolley wheel to bear against the guiding flange. Its position in relation to the curve of smaller radius is determined as before.

It will be noticed from the diagram that the position for the frog with a four-wheeled car with trolley pole in center of car is considerably in advance of the position in which it would be placed for a double-truck car with the trolley pole in the center of car.

In the case of a very sharp curve, the position for the frog is sometimes at a spot before the points are reached. As the radius increases the position for the frog moves toward the curve in advance of the points. If the turnout were always a true circular arc the position of the curve traced out by the trolley base could be tabulated, but in almost every instance it is a transition curve, and the most practical method is to measure the versine of a cord equal in length to the distance between the truck centers.

SYDNEY TRAMWAYS—FROG LOCATIONS FOR DIFFERENT COMBINATIONS OF CARS AND CURVES

With the increase in distance between the leading and trailing tongues of the frog, it has been necessary to maintain the trolley wheels more carefully to insure that the planes of the trolley wheel and trolley pole coincide. The carhouse foremen have a special tool for making the necessary adjustments.

It might be added that there are approximately 900 frogs on the Sydney system, and that at some of the busy junctions from 1200 to 1500 cars pass over the same frog during the period of twenty-four hours.

A Home-Made Anti-Straddler

BY K. A. C.

In electric railway operation no condition is so annoying to the operator as that met with in facing switches and generally known as "splitting." The causes for this are quite common and the results frequently disastrous. The accompanying diagram illustrates, in detail, a simple and effective preventive device recently adopted as a standard by one of the large Eastern systems.

Up to the present time this company has had in service numerous devices for the same purposes but all have been found deficient in some respect, some because they were too complicated and others because they were adapted to but one style of switch. After patient experiment with these contrivances it was finally decided to attempt the manufacture of one which would be simple and applicable to any switch in use, and the one herein described is the result. It has proved satisfactory under all conditions and is now in service generally, our own shops manufacturing all the parts.

This anti-straddler contains, exclusive of the box and bolts, nine parts, which are simple and strong, making renewals and repairs economical and easily performed. The parts *C* and *G* and *F* are the only wearing parts; the parts *I* and *E* which are bronze and steel respectively, resist wear to a very satisfactory degree.

The device can be assembled and maintained by an ordinary trackman. Drainage is obtained by means of a hole in the back of the box and consequently this particular requires little attention. All adjustments are made, after the original installation, by means of the nuts *J* and *K*, which are of steel on a bronze screw.

This device is not only an efficient anti-straddler but it can be applied to a spring or derail switch by lengthening or shortening the hold on the tongue rod *F*, according to which way the switch is to be set, so that the throw of the switch will not pull point *X* over center. The different styles of lugs can be cared for by fashioning this rod. The box will fit any of the numerous 9-in. construction switches in use. It can be entirely dismantled without removing any paving. The cover is so designed with lugs that it will remain stationary and be safe for horses and vehicular traffic, even under the most severe trucking.

DETAILS AND BILL OF MATERIAL OF ANTI-STRADDLER DEVISED FOR USE ON A LARGE EASTERN CITY SYSTEM

A Suggested Car-Mileage Meter

BY A MISSOURI CONTRIBUTOR

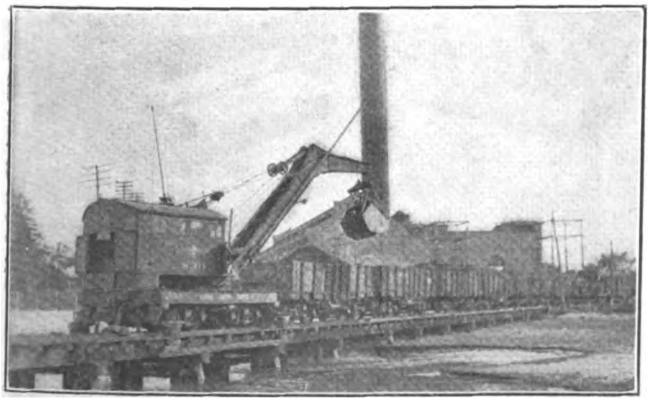
The system of keeping account of the number of miles a car has traveled by figuring up the number of blocks on the route does not seem to be a very accurate one because cars are sometimes switched from one line to another during heavy traffic. Also when trippers are used a few hours in the morning and evening a lot of figuring would be required, after six months of service, to tell how many miles the car had run.

I wish to suggest a system that would be accurate and labor-saving, namely, the use of a meter to register the number of miles traveled. If some manufacturer will put a meter of this order on the market it will do away with much clerical work by the railways. The meter should be made without any time attachment, as it is not wanted as a speed indicator, but it should register plainly the number of miles traveled—say, up to 100,000 miles or whatever other figure is desired.

Suppose a car is equipped with this meter. Then a card index can be kept with the names of the different equipment parts of the car, such as armature bearings, fields, motor bearings, etc. When the car is disabled or turned in the shop man, by referring to the card, will be able to see in a moment how many miles of service have been given by the part which has failed. After repairs, the number of miles shown by the meter could be recorded or the meter could be reset to zero. This meter need not be complicated or expensive.

Under-Water Coal Storage of Illinois Traction System

The Illinois Traction System has two large under-water coal-storage tanks, one located midway between its Peoria and Bloomington plants and the other close to its Riverton plant. The accompanying halftone shows the method of reclaiming coal from these storage tanks. This view was taken at Riverton, and illustrates the use of the company's wrecking crane for loading wet coal into the cars for transfer to the power-station bunkers. Briefly, this pit may be described as a reinforced concrete reservoir, 225 ft. long x 120 ft. wide x 20 ft. deep. Its walls and sides are of 10-in. reinforced concrete slabs protected with a waterproof coating. Along the middle of the storage tank is a timber trestle on which the coal cars are run for loading and reclaiming the fuel.

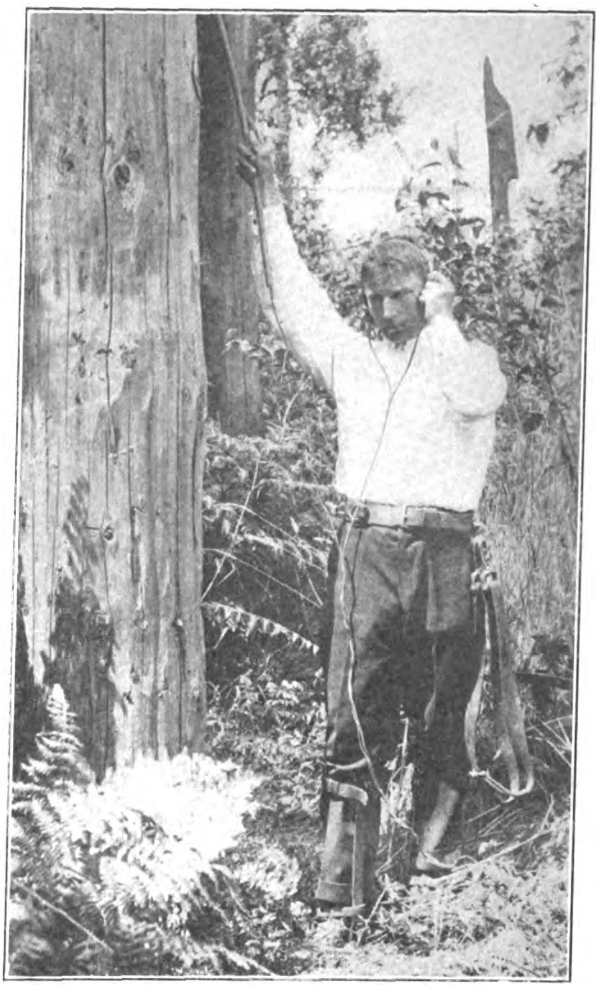


ILLINOIS TRACTION WRECKING CRANE RECLAIMING COAL FROM UNDER-WATER STORAGE TANK

It is stated that the two coal-storage tanks have been very profitable investments. The Illinois Traction System has physical connection with more than 100 mines, and when fuel, especially screenings, can be bought at a particularly low figure, the coal-storage tanks provide capacity for economical under-water storage. This fuel is kept without loss in heat value until such time as a general scarcity of screenings arises and much higher prices prevail.

Detecting Defective Insulators

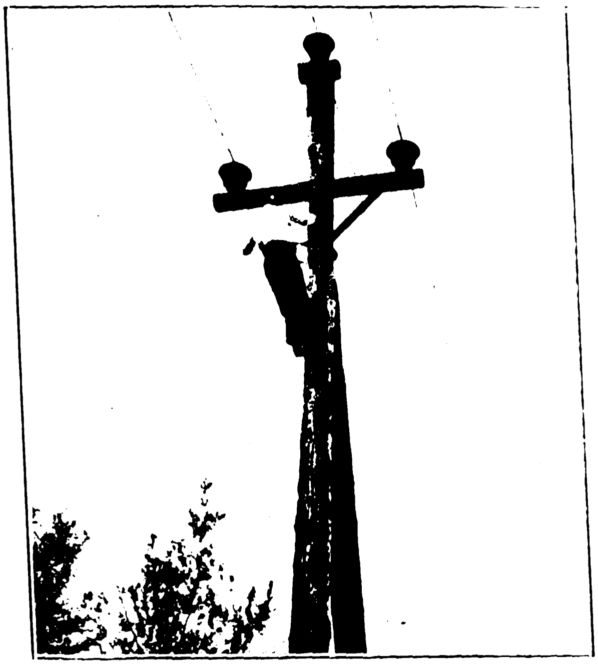
On the system of the Puget Sound Traction, Light & Power Company, of Seattle, Wash., M. T. Crawford, in charge of the transmission lines, has devised a convenient and rapid means for detecting defective insulators. The scheme was outlined briefly at the Pacific Coast meeting of the A. I. E. E. in Spokane, Wash. Recently the porcelain pin insulators used on one of the company's lines began to give a great deal of trouble. Investigation showed that the insulators do not usually have a large radial crack, but that a small crack starts on the head or in the side groove and extends around on the top of the insulator. These cracks enlarge until a leakage current starts through the top two or three shells and discharges over the surface of the lower shell. The tendency of a brush discharge to pass in the positive direction more than in the negative has a rectifying effect on the leakage current. This results in a unidirectional current from the bottom shell to the pin, and signs of electrolytic corrosion of the pinhead in the cement have frequently been found. Once started, this will soon crack the entire insulator, as the high tensile stress put on the porcelain by this internal expan-



TESTING LINE FOR DEFECTIVE INSULATORS

sion will lower its dielectric strength. In many cases insulators have been found which were leaking noisily, and when the line was killed and an examination made the insulator was found intact, although a number of cracks were visible. As soon as the tie wire was removed, however, the entire insulator fell apart.

The expense of replacing all of the insulators was prohibitive, and the practice heretofore was to replace them one by one when the leakage became so great that it could be detected from the ground. As they were at an advanced stage of deterioration before this condition was reached, and frequently failed, causing an arcing ground that punctured other insulators, a heavy charge against maintenance resulted because of the emergency nature of the repair work. In locating defective insulators at first, use was made of a megger, but unless the testing wire was over the leaking crack and this crack extended clear through to the pin, the result was unsatisfactory. After considerable experimenting, a device was perfected by which these insulators could be located at an early stage of the depreciating process. This enabled them to be replaced economically and before they finally broke down and damaged other insulators or interrupted service.



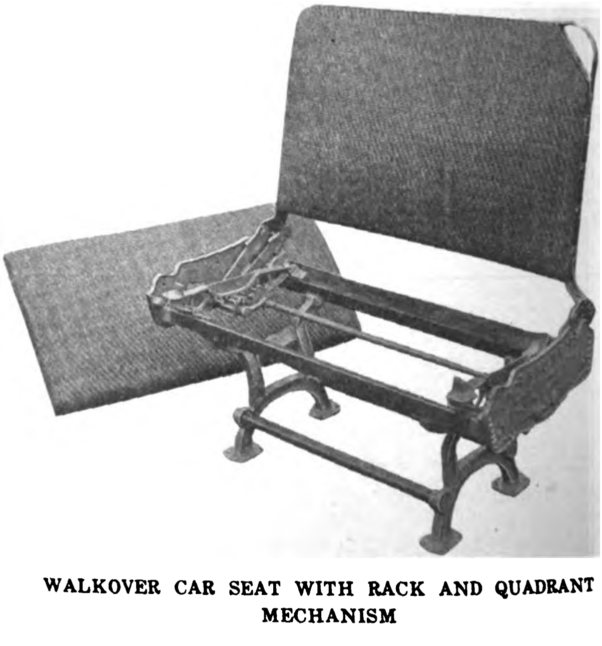
LOCATING DEFECTIVE INSULATOR

The device used for this purpose is shown on page 1065. It consists of a pair of 2000-ohm wireless-telegraph receivers fitted up for the convenience and safety of the inspector in testing. A hand pick is driven into the pole about 7 ft. from the ground, and a pin is driven into the ground several feet from the pole. The receiver set is connected between these two, and if all insulators are sound, there is a clear audible hum of the same tone as the telegraph line due to the shunting of a part of the capacity current of the insulators on the pole top. If, however, an insulator is leaking, a scratching noise is superimposed on the hum which comes and goes as the neutral shifts to and from the wire on the defective insulator. The inspector then climbs the pole and tests between each insulator pin and the center of the cross-arm and thus locates the defective insulator. The device can be used in a similar manner on steel tower lines. Insulators can be found in this way which have started only a very small crack and which will not puncture on the test below 100,000 volts. Insulators with a crack clear around the head were taken off and tested, puncturing at from 60,000 volts to 65,000 volts, but no sound was audible from them while on the line without the use of the detecting set. One or two lower petticoats were usually found intact, the leakage current passing over their surface during the test until the puncture point was reached. In the device used on the Puget Sound lines the hand pick consists of an insulated tube with a sharp-pointed steel terminal on one end which is thrust into the pole or cross-arm. The other terminal, which is driven into the ground or in the pole under the cross-arm in locating the insulator, consists of a sharp steel pin. A fuse and short-circuiting jack with plug on the receiver set is inserted in the circuit if there is any probability of a considerable voltage to ground.

A Cross-Seat with Rack and Quadrant

The name "Triumph" has been given by the United Electric Car Company, Ltd., Preston, England, to a new form of walkover seat, thousands of which have already been bought by several of the larger English tramways. The mechanism for operating the seat back is the special feature, as will appear from the following explanation.

The seat is carried on a tilter with angle corner stops on the upper side in place of the usual dowel pins, thereby permitting the seat to be easily fitted in position, even in the dark. On the bottom of the tilter is arranged a rack, which engages a quadrant carried on a stud. This quadrant is wide enough to engage with another quadrant which is secured on a solid steel shaft. A similar quadrant is fixed on the other end of the shaft and operates a similar mechanism, to insure the travel of the seat in a parallel direction. The back is carried on two short operating levers at each side, one of these levers being fixed to the solid steel shaft, while the other is carried loose on a stud which also carries a quadrant. All the castings are made of the finest malleable cast iron and are set and drilled to jig so that all parts are interchangeable. The seats can be supplied in any type and upholstered in any kind of material. The invention is that of J. E. Anger, manager of the United Electric Car Company, Ltd., and patents have been taken out in England and other countries.



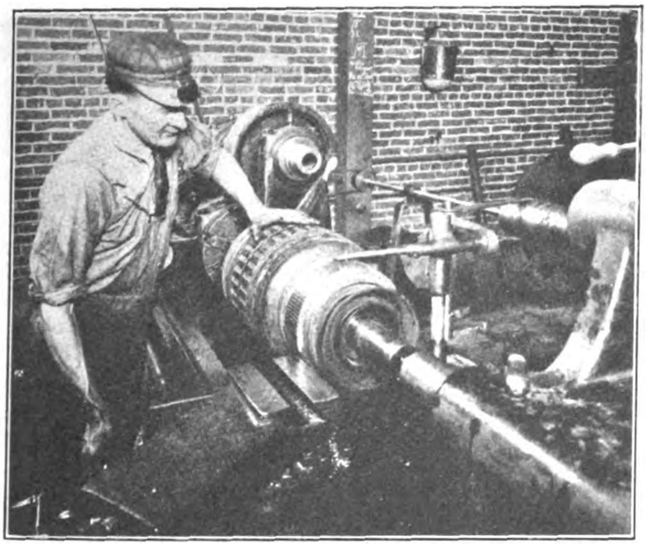
WALKOVER CAR SEAT WITH RACK AND QUADRANT MECHANISM

Actual Uses of a Double-Spindle Lathe

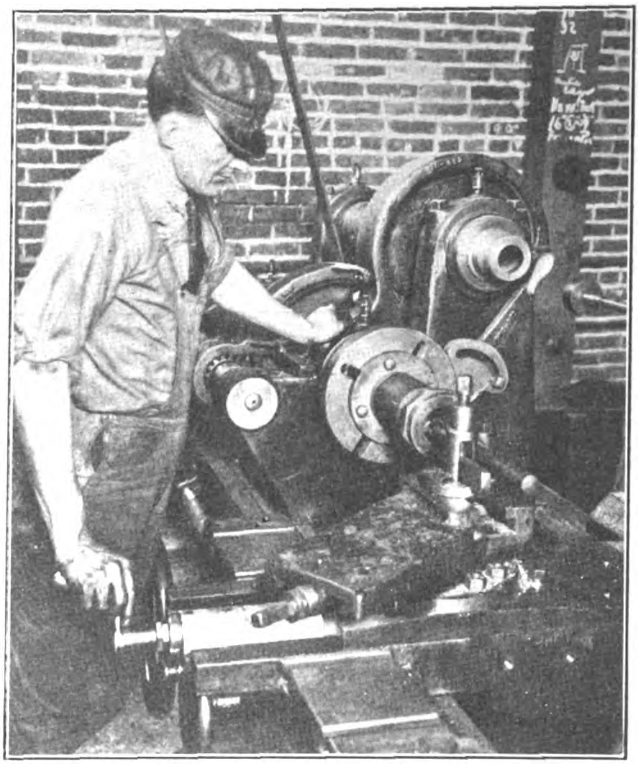
The "2-in-1" lathe with 26-in. back-geared and 48-in. triple-geared swing lathe, made by J. J. McCabe, New York, is a familiar object in many electric railway shops which are not large enough to keep specialized tools reasonably busy. Even the largest companies, however, find good use for this lathe. Thus one of the largest systems in the country uses three as stand-by wheel lathes in addition to handling miscellaneous jobs like the turning of piston rings for the power plants. Some of the possibilities of this machine were revealed recently in visiting one shop in Connecticut and another in New Jersey.

On the Connecticut railway the lathe handles the total repair input of eight sets of wheels a week in addition to a great variety of other work. If used for wheel work alone the lathe can turn out four to five pairs of wheels a day. When used as an ordinary lathe, the large faceplate is removed by means of a block and tackle overhead. This particular lathe is driven by a 7½-hp motor, the control and drive of which embody several commendable features. Thus the lathe movement is controlled from the center of the tool so that the operator does not have to walk over to the motor at the headstock every time he wants to throw the switch. The controller is covered with a wooden casing, which also protects the men from contact with the gearing. Formerly, the circuit breaker was mounted on the motor but it is now mounted on a column because in the old position the jarring of the lathe during the making of heavy cuts sometimes opened the breaker.

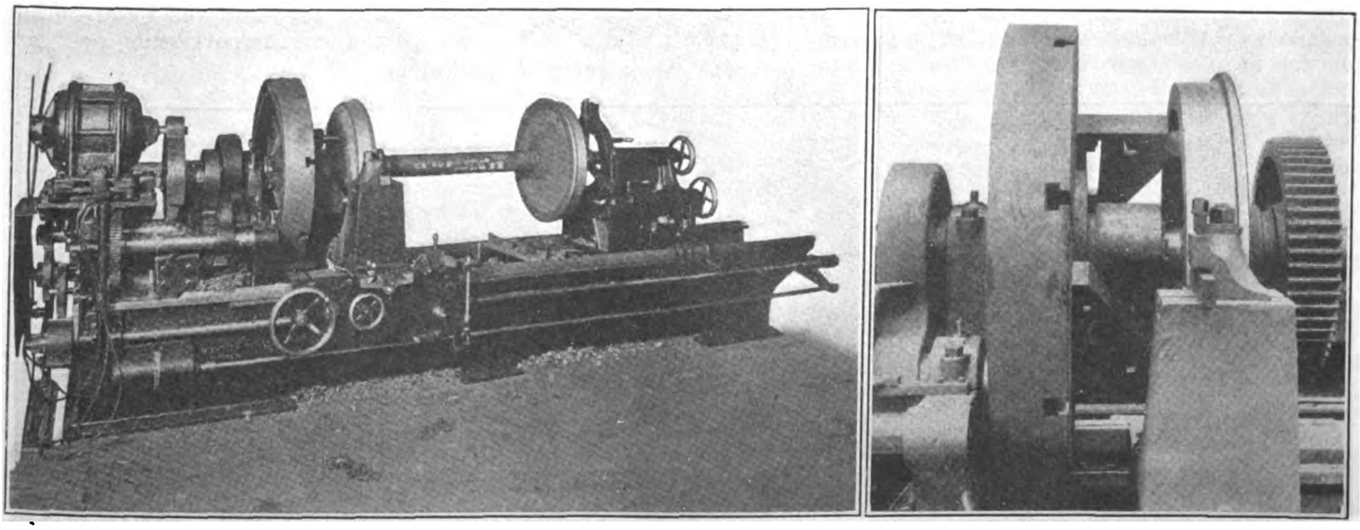
In the New Jersey shop the lathe is belt-driven. It handles anything from the turning of 34-in. diameter steel wheels to the boring of axle and armature housings and compressor cylinders. Among its special applications are threading bolts, making pipe couplings and crosshead keys and boring valve bonnets. This lathe, as adapted for slotting commutators, is shown in one of the illustrations. The frame for the shaft pulleys and idlers of the slotting drive is of heavy bar iron bolted to the base of the lathe. The saw arbor is sleeved on a vertical post with a stop for adjusting it to any desired height. The perfect alignment and the reciprocating movement of the armature are provided by its position in the lathe without the use of extra fittings.



COMMUTATOR SLOTTER ATTACHMENT IN USE ON A DOUBLE-SPINDLE LATHE



DOUBLE-SPINDLE LATHE IN SERVICE FOR THE TURNING OF ARMATURE BEARINGS



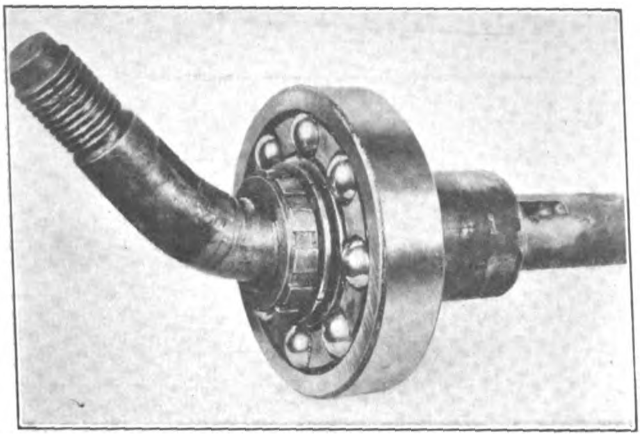
MOTOR-DRIVEN DOUBLE-SPINDLE LATHE SET UP FOR WHEEL WORK; WHEEL TURNING REST AND WHEEL-TURNING ATTACHMENT USED TO INSURE GOOD GRIP AND FREEDOM FROM CHATTERING

The same lathe may also be fitted with an emery wheel to grind flat spots on chilled iron wheels.

The maker calls special attention to the new wheel-turning rest and wheel-holding attachment illustrated in detail alongside the general view of the complete lathe. These changes improve the grip on the wheels, eliminating chattering and insuring uniform cuts.

Strength of Ball Bearings Proved by a Collision—Some Installations

The accompanying illustration is a striking example of what the standard S.K.F. No. 412 size ball bearings, now applied to electric railway motors and car lighting generators, will withstand. This is an armature shaft taken from a car lighting generator which has been in a wreck. The shaft, which was of 1½-in. flanged steel, was bent over the ball bearings as a fulcrum. From the illustration it will be noted that, although there is no crack in the steel at the bend, there is a double wrinkle on the top side, which gives an idea of the great stress imposed upon the ball bearing when the wreck occurred.



SHAFT BENT IN WRECK WITHOUT AFFECTING BALL BEARINGS

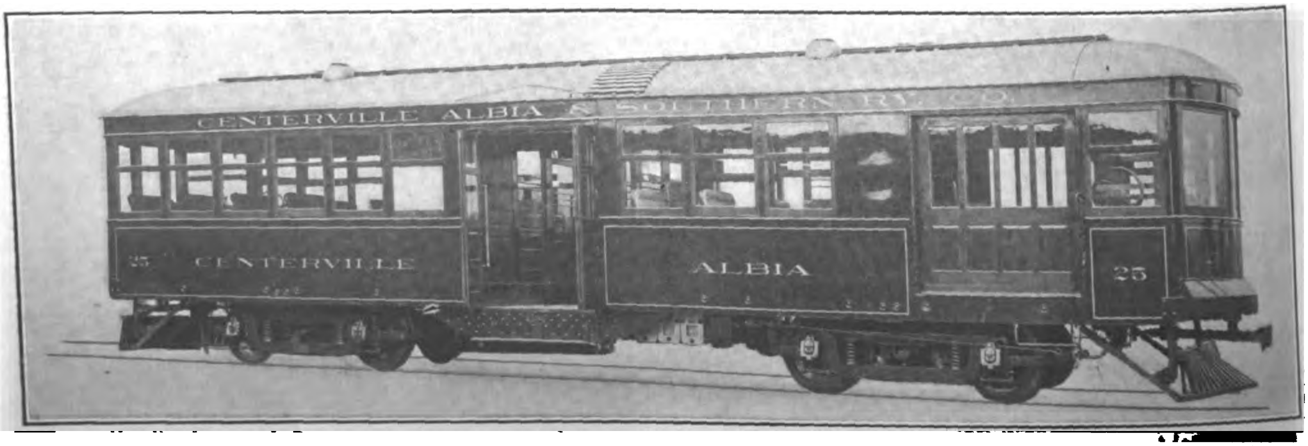
Assuming a strength of 60,000 lb. per sq. in. a force of 23,000 lb. applied 3 in. in from the face of the bearing would be required to bend this shaft. As a matter of fact, each 1-in. ball would stand a crushing load of 97,000 lb. so even under such severe service as a wreck there is a good factor of safety for the ball bearing.

The car to which this generator was applied was a Santa Fé combination coach and mail car. The accident, which occurred on the Colorado Southern Railway tracks in Colorado, was caused by high water. The engine went through a culvert, with the baggage car on top of it and the combination coach and mail car crashing on top of that. The dynamo pulley was entirely broken up, only the hub remaining. The suspension of the dynamo, which was a Bliss type "O," was badly bent, and the generator frame was sprung out of round, so that two of the pole faces bound on the armature, causing trouble in removing it. The armature itself, which was mounted on two ball bearings, was not damaged in the least, and as soon as a new shaft was applied it was ready for service. Neither of the ball bearings showed any effect of their strenuous experience and have been returned to service. Both end housings of the generator covering the bearings were so badly broken that they had to be scrapped.

S.K.F. bearings are in use now on sixty-five cars of the Third Avenue Railway System, New York. Ten storage battery cars were equipped in October, 1910, with both journal and motor bearings, and in June, 1913, the company ordered thirty additional equipments. The excellent service which these bearings have given is emphasized still further by an order placed in September, 1914, for the equipment with journal bearings of twenty-five radial truck low-level trolley cars. The S.K.F. Ball Bearing Company has also recently furnished journal bearings for two Brill storage-battery cars of the Carolina Traction Company, Rock Hill, S. C., and for one Brill storage-battery car of the Cambria & Indiana Railroad, Colver, Pa. The last is a double-truck car operated at a schedule speed of 18 m.p.h., and the weight on the eight journals is fully 56,000 lb.

Combination Passenger and Baggage Side-Entrance Car

The Southern Iowa Traction Company has lately received from the American Car Company two 45-ft. 2-in. arch-roof interurban cars, as illustrated, which are unusual in combining the side-entrance feature with a standard passenger compartment, a smoking compartment and a baggage room. This design is 9 ft. wide over the sills and 9 ft. 4 in. over the trolley boards. A motorman's cab with hinged door is built in at opposite corners of the car. Four-leaf folding doors are used at the side entrance, a single hinged door is installed for each passenger compartment and the usual sliding door is provided for the baggage room except that the upper panels are of clear glass. The car underframe is of steel and wood while the sides are sheathed with steel. Each car is mounted on two Brill 27 M.C.B.-1 trucks equipped with four Westinghouse 323-A motors and K control. Other specialties on these cars are Nichols-Lintern air sanders, Hale & Kilburn reversible seating, Dayton sash fixtures, Ohmer registers and Peter Smith heaters. The two passenger compartments per car seat thirty-eight people.



SIDE-ENTRANCE CAR FOR SOUTHERN IOWA TRACTION COMPANY WITH ONE BAGGAGE AND TWO PASSENGER COMPARTMENTS

LONDON LETTER

Tramway Receipts and Extensions and Parliamentary and Civic Matters Are Reviewed

(From Our Regular Correspondent)

The effect of the war on tramway systems is reflected in the official returns of sixty of the principal tramway undertakings of the United Kingdom for the week ended Sept. 19. The report for this period shows total receipts of £226,838, or £7,747 less than in the corresponding week of last year. Receipts were at the rate of £79 4s. 7d. per track-mile, a decrease of £3 8s. as compared with last year.

The general manager of the Belfast Corporation Tramways has reported that since the outbreak of war the tramway receipts have decreased about £450 weekly, some 130,000 fewer passengers being carried. To meet this decrease he has been taking measures to arrange the tramway service week by week proportionately to the public requirements. He and his committee have received the support of the City Council to the steps so far taken.

The tramways department of the Glasgow Corporation has been able to resume the normal services of cars. Owing to the remarkably loyal response of the tramwaymen to Lord Kitchener's appeal for additional soldiers, the car service suffered considerably from the thinning in the ranks of the staff. In filling the vacancies married men who in ordinary circumstances were not eligible for the new army were selected first. Many of these men have since been trained for tramway work, and a full service is now available.

The Leeds tramways department is hurrying several pieces of work, with the object of providing employment for those who are out of work. The construction of the new tramway line at Guiseley will also be proceeded with, and a start is to be made with the erection of the overhead equipment for the railless cars which will run from the White Cross, Guiseley, through Otley to Burley. It is hoped also to begin the construction of the tramways extension from York Road to Halton.

The Leeds tramways department is hurrying several pieces recommended that the town clerk be authorized to make all necessary preliminary arrangements for the promotion of a tramways bill in the next session of Parliament. It is understood that the bill will include provisions for the extension of the tramways to Elland and to Stainland and for the operation of motor omnibuses to Ripponden and Cragg Vale. It may possibly be proposed to extend the tramways from the center of Brighouse borough to Rastrick. Nearly two years ago the ratepayers rejected a Parliamentary bill for these extensions and some street widenings in Halifax. Since then Huddersfield has taken trams to Elland, and Halifax traders have asked the tramways committee to construct lines to Elland and Stainland.

After a few tri-weekly performances, the experimental electric trolley bus at Hove has been withdrawn. It is understood that the vehicle has served its purpose for the time being. One of the objects of the experimental installation was to ascertain the relative efficiency of the over-running and under-running trolley systems in its bearing upon the scheme prepared by the Brighton authorities for the "through route" service.

As the result of the passing of the Bristol Corporation tramways bill, 1914, the corporation is prepared to work the local tramways if it exercises its power to acquire the property of the Bristol Tramways & Carriage Company. The tramways committee recommends that, before giving notice to purchase, it be authorized to negotiate with the company with the view of ascertaining what rent or other sum the company would be willing to pay to the corporation if the latter agreed to refrain from exercising its option of purchase for seven, fourteen or twenty-one years.

The tramway committee of the Edinburgh Town Council has discussed a draft minute of agreement between the Lord Provost, Magistrates and Council of Edinburgh and the Edinburgh & District Tramway, Ltd., and Dick, Kerr & Company, Ltd. (lessees of the Edinburgh Corporation Tramways). It is provided in the draft agreement that the corporation shall take over the rolling stock, cables and other plant used by the tramway company in working the tramways under the lease and that the tramway company shall sell and deliver the same to the corporation on the expiration of the lease, namely, on June 30, 1919, or at an earlier date if agreed upon between the parties. The tramways company is to continue to maintain and, where necessary, replace the stock during the lease. The price to be paid by the corporation on the transfer of the stock and effects is to be fixed, failing agreement, by an arbiter to be agreed upon between the parties or to be appointed by the Board of Trade. In fixing the price the contingencies of the cable system are to be kept in view, but without any consideration of good-will. It is further provided that the tramway company is to allow the corporation, free of charge, to experiment with self-propelled cars upon such portions of the present tramways as may be arranged between the two parties, the trials, however, to be so conducted as not to interfere with the ordinary working of the system. The tramway company is not to be responsible for any loss or injury through such experiments.

At the last meeting of the Edinburgh tramways committee a proposal was considered for providing a tramway to Queensferry. Two alternative routes are to be considered by a sub-committee.

The London County Council wishes to install the overhead trolley system in two streets in Stepney, but the proposal is opposed by the Borough Council, which desires the underground conduit system. In a report on the subject the works committee states that the Borough Council has most consistently adhered to the opinion that the only system of traction suitable for the two roads is the underground conduit system.

The London County Council has authorized a plan to bring before Parliament proposals respecting the establishment of a new electricity undertaking for Greater London. The details have not yet been submitted to the finance committee, but the draft was sanctioned in order that it may be dealt with without delay by Parliament. The proposals, roughly, mean a combination of municipal and private enterprise designed to insure full control by, and an adequate share of profits to, the public, with the flexibility and commercial enterprise of company management. The best features of both systems of working will thus be retained. The scheme involves the co-operation of the authorities in outer London with the London County Council, but no compulsory purchase of existing undertakings will be entailed.

The London & South-Western Railway has just issued £1,000,000 of preference stock, redeemable in ten years. The proceeds are required for the large electrification scheme which is being carried out on the company's Thames Valley suburban system. When the war broke out a temporary suspension of the work was ordered. The tracks are well advanced and the conductor rails have been laid over many miles of the first section of lines. The high tension distributing cables, carried on brackets on short posts alongside the railway, are also in position for long distances. The generating station, which is being erected at Wimbledon, is nearing completion and should soon be ready for the electrical machinery.

With regard to the extension of the electrical equipment of the London, Brighton & South Coast Railway, much of the electrical material hitherto has been secured from the Allegemeine Elektricitäts-Gesellschaft, Berlin, from which, of course, delivery cannot now be obtained. As is well known, this line has been equipped on the single-phase, high-tension system, the Berlin firm having been the contractors for the electrical portion of the work since the original electrification scheme some years ago. Nothing has yet transpired to indicate that any transference of the contracts for equipment will be made by the London, Brighton & South Coast Railway.

The ceremony of transferring the Kelham Island power station from the tramways committee to the electric light committee of the Sheffield Corporation has been formally carried out. The transfer was made as a result of a recommendation by a joint sub-committee of the tramways and the electric supply committees. All current supplied to the tramway feeders and for Board of Trade requirements, except certain booster units, is to be charged at the flat rate of 0.8d. per unit. This price is subject to a revision at the end of three years, and is based on the conditions already existing at the station and the present system of distribution.

News of Electric Railways

INDIANAPOLIS LABOR SITUATION

Federal Court Injunction to Prevent Strike on Indianapolis Traction & Terminal Company

Hearings were held in the United States Circuit Court at Indianapolis on Oct. 27, 28 and 29, on the petition of the Guaranty Trust & Safe Deposit Company, Philadelphia, trustee under the mortgage of the Indianapolis Traction & Terminal Company, for an injunction to prevent W. D. Mahon, other officials of the Amalgamated Association and labor leaders in Indianapolis from attempting to induce trainmen to violate the award of the arbitration board made on Feb. 9, 1914, and go upon a strike, and to prevent the men individually and as a body from violating the arbitration award contract. At the close of the hearing Judge Arthur B. Anderson declared his intention to grant a temporary injunction, pending litigation.

A temporary restraining order was issued by Judge Anderson in this case on Sept. 23 when attorneys for the plaintiff appeared in the Federal Court and showed that an effort was being made by officials of the Amalgamated Association from Detroit to bring about a strike that night on the lines of the Indianapolis Traction & Terminal Company in violation of the award contract. This action was referred to in the ELECTRIC RAILWAY JOURNAL of Oct. 3, page 640. Oct. 2 was then set as the date of the hearing, but the case was postponed on request of attorneys for the union.

During the hearing nineteen persons were called as witnesses. The case against the labor leaders was presented in such thorough detail that practically no effort was made by their attorneys to controvert any of the facts by cross-examination of the witnesses, and this was commented upon by the court at the close of the arguments. Ralph Belch, business agent and secretary of the local, admitted on the stand that an affidavit signed by him, stating that twenty men were discharged by the company for the sole reason they were union men, was not true, and he asked the forgiveness of the court. Judge Anderson called the attention of the witness to the penalty for perjury and reminded him that the Federal grand jury met the following week. A long deposition of W. D. Mahon, international president of the Amalgamated Association, containing copies of correspondence between the officers of the local and officials of the Amalgamated Association at Detroit was entered as part of the testimony. It showed that appeals were made for a "leader" to come on and save the situation at Indianapolis, as men were continually leaving the union and signing the company's service contract, until now the company had more than 70 per cent of the men signed up.

The correspondence further showed that since last May plans had been discussed for calling a strike; that they were only seeking an opportune time, and that they now felt their last chance was slipping by. It was further shown that a drastic ordinance which had been passed on Oct. 19, 1914, by the City Council of Indianapolis, providing for thirty days' instruction for new motormen and conductors on both city and interurban cars by men who had been in the employ of the company at least one year, and providing a penalty of $300 a day for each man allowed to operate a car in violation of the ordinance, was prepared by Secretary Reeves of the Amalgamated Association at Detroit and sent to the local officers of the union to have put in shape by their attorneys and passed by the Indianapolis City Council. Mr. Latta, attorney for the plaintiff, showed that in the case of a strike it would have cost the company in penalties $100,000 a day to operate its cars, under the ordinance. This ordinance has since been vetoed by Mayor Bell of Indianapolis.

Edward McMorrow, member of the executive board of the Amalgamated Association, admitted that he called on the various labor leaders in Indianapolis and that he was to address the men at the midnight mass meeting on Sept. 24 which was interrupted by a United States marshal serving notice of the restraining order. He said to the men at the meeting that "there were some things I had intended saying which I can't now talk about." Being questioned by the court as to what they were, he declared they were in reference to the "wonderful benefits of membership in the Amalgamated Association, its insurance benefits, and many things too numerous to mention." Judge Anderson later remarked that there was no question but that Mr. McMorrow had intended to talk about a strike and nothing else. Mr. McMorrow admitted that he had advised the renting of vacant houses or other property adjacent to the carhouses for use as headquarters for bodies of men in case of a strike.

W. D. Mahon followed Mr. McMorrow as a witness. He admitted sending Mr. McMorrow to Indianapolis and that Mr. McMorrow reported to him and six members of the executive board at Chicago on Sept. 20. Mr. Mahon's testimony showed that the 50 per cent of the dues from the Indianapolis local received at Detroit had decreased from $626.50 in November, 1913, to $343.50 in September, 1914. During that time $9,000 had been expended on the Indianapolis local.

The question of the company's service contract was one of the principal subjects of argument. The attorneys for the union had filed with their answer a cross-bill asking for injunctive relief against the Indianapolis Traction & Terminal Company in what they claimed was a violation of the arbitration award contract. It was shown by Mr. Winter, counsel for the plaintiff, that as this cross-bill was brought by a co-defendant to a suit it had no validity whatever and could not be considered. The court expressed willingness to hear any evidence which might show that the individual or "service contract" was in violation of the award contract of the Public Service Commission, but attorneys for the Amalgamated Association said they did not care to submit any evidence but would argue the case.

The service contract was a result of the award of the Public Service Commission of Feb. 9, 1914, which contained a provision that each motorman and conductor should be permitted and required to be off one Sunday in each month, and that they should be permitted and required to have eight consecutive hours' rest between runs. The award also provided a minimum wage of $45 a month for extra men. Under these conditions the company found it impossible to take care of the extra baseball, park and theater travel on Sundays and holidays. The company therefore drew up a contract substantially in the same form as the arbitration contract, but with provisions which permitted car service men who signed this contract to work during all Sundays if they so desired, and providing eight hours rest in each twenty-four hours, but not necessarily eight consecutive hours between runs if the public service should at times prevent it. All the non-union men signed this contract and also many of the union men. In fact about 70 per cent of the men became parties to the modified contract. Officials of the Amalgamated Association had sought before the arbitration board, consisting of three members of the Public Service Commission of Indiana, to prove that the service contract was invalid and conflicted with the award contract in the agreement as to working conditions. The arbitration board held that the contract was valid in all provisions in which it did not conflict with the award contract, and that if the company succeeded in getting all the signatures of the employees to the service contract that instrument would then become effective in all particulars.

Judge Anderson, in the injunction hearing, held that the company was not in any way violating the award contract by securing signatures to the service contract, and that it was his opinion that the men who had not signed the service contract could not in any way interfere with those men who had signed it enjoying the privileges it provided; that it was very evident that the company could not secure all the names at once, and the fact that it had already secured 70 per cent, and was still continuing to secure signatures was very much in the favor of the company and could not be criticised.

Mr. Latta, in summing up the case for the plaintiff, asked the labor attorneys if they intended to rely on the Clayton bill in seeking to defeat the granting of an injunction by the court. Upon an affirmatory answer, Mr. Latta argued that the Clayton law was not applicable in this suit, quoting from Section 20, which provides that no judge may grant an injunction or restraining order in cases "between an employer and employees, or between employers and employees, or between employees, or between persons employed or persons seeking employment, involving or growing out of a dispute concerning terms or conditions of employment, unless necessary to prevent irreparable injury to property, or to property right, of the party making the application, for which injury there is no adequate remedy at law." It was shown that the plaintiff, the Guaranty Trust & Safe Deposit Company, is in none of the positions set out in the law, but is in the position of third party holding rights under a contract. The rights of the bondholders are involved, and there could be no adequate remedy at law because the Amalgamated Association (not being an incorporated body) and the other parties set out in the complaint could not make reparation for the damages set out as about to be sustained. Mr. Latta pointed out the unconstitutionality of the Clayton bill, in that under the constitution Congress has no authority to take away the power of the Federal Court, and it follows of necessity that Congress cannot take away the means of enforcing the power held by the court under the constitution. Judge Anderson in the remarks which he made following the argument concurred in this opinion.

Mr. Esarey, attorney for the Amalgamated Association, sought to show that the Federal Court could not enjoin further proceedings in the suit for receivership in the Marion County Circuit Court, in which William Dobson, secretary of the Bricklayers, Masons and Plasterers Union, is seeking to have the lease of the Indianapolis Street Railway to the Indianapolis Traction & Terminal Company cancelled. It was shown by depositions and testimony that five shares of stock were purchased by Mr. Dobson, after conference with labor union leaders, at the time of the strike in November, 1913, and the suit was brought and has been maintained in court for use in case of another strike, "to force the company to come to terms." Judge Anderson interrupted Mr. Esarey's argument by saying that such a suit could not be upheld in any court, and that he would not take time to discuss the matter, but that if he should think it necessary he would enjoin any such proceedings, and that it was his intention to issue such an injunction as would prevent "the raiders from the north—these citizens of Detroit" from interfering with the affairs of the company in Indianapolis.

Judge Anderson took exception to the closing argument of Frank S. Roby, one of the attorneys for the Amalgamated Association, in which Mr. Roby asked for an injunction against the company, intimating that such a decision should be made in answer to a demand by public opinion if an injunction was also issued against the men striking. The court said that if public opinion was represented by Mr. Roby it was founded upon a misapprehension so far as the evidence before him showed. "I think it is about time for us to take stock in the facts and not indulge in too much loose talk about public opinion," said Judge Anderson. "If I were manager of a property, I would discharge any man who stole from us; I would discharge a man if he got drunk; I would discharge a man for disobeying or violating rules—and the fact that he was a union man would not affect it at all." He said that the uncontradicted evidence showed that no man was discharged because of his union affiliations, and none was reinstated because he dropped out of the union. He said that the defendants themselves admitted that their charges to the contrary were untrue.

The temporary restraining order was then extended by the court for ten days, in order that attorneys for the defense might be given an opportunity to file briefs in connection with their cross bill for an injunction to prevent the company from putting its service contract into effect before it has secured the signatures of all the employees.

INJUNCTION GRANTED IN FRANCHISE CASE

The South Covington & Cincinnati Street Railway has been granted a restraining order by Judge A. M. J. Cochran of the United States Court at Covington, Ky., against the city of Covington to prevent its accepting bids for a new franchise over its streets. The court holds in short that the South Covington & Cincinnati Street Railway has a perpetual franchise in the streets of the city. While the order was not made permanent, it is believed that the final decree will not be different.

The movement to receive bids for a new franchise on the streets was inaugurated by former City Solicitor S. L. Blakely in behalf of the General Council and the company, in order to protect its rights, asked for an injunction. It asserted that receiving bids would work irreparable damage to its interests, cause the destruction of its rights and that it would be deprived of its property without due process of law.

The company contended that it owns a perpetual franchise on all the streets occupied, with the exception of the Rosedale line, and that the ordinance of 1864, limiting the street railway franchise granted thereunder to twenty-five years, was not of a general nature and applied only to the Covington Street Railway, which was referred to in the ordinance. When Council, therefore, enacted the ordinance of 1869, giving Mr. Abbott and others the right to construct and operate a railway on certain streets and made no mention of a date of expiration, with the exception of the statement that the grant shall terminate upon the failure of the company to construct its lines and operate its cars or fail to pay the annual stipend, it was the intention that no limit should be placed upon the right as long as these requirements were complied with fully.

Judge Cochran said that it is not necessary that the grant should state in so many words that it is perpetual. Among other things he said:

"Both in the ordinance of Dec. 13, 1869, and the contract of Dec. 23, 1869, made pursuant thereto, it was provided that the defendant (the city of Covington) granted Abbott and associates 'all the authority and right' that it had 'the capacity to grant.' We have seen that it had the capacity to grant to them a perpetual franchise. The provision, then, that there was granted all the authority and right that the city had the capacity to grant was the same as if it had said in so many words that it granted the perpetual franchise. The English language is not so poor that the same idea cannot be expressed."

The court further said that in 1882 the city granted the South Covington & Cincinnati Street Railway a franchise expressly stipulating that it was to operate under the Abbott grant.

NEW KANSAS CITY STATION OPENED

Kansas City's new Union Station was formally opened to traffic at 12:01 o'clock the morning of Nov. 1. A celebration was held on Oct. 30 and 31 which brought many thousand visitors to the city over the railroads and interurbans, and resulted in local traffic over the Metropolitan Street Railway which perhaps established a record. A feature of the celebration was an industrial parade by local manufacturers, with nearly 150 floats. The operation of cars on streets in the business district was suspended during the parade.

Some of the reroutings due to the opening of the station began Friday with the passing of one line through the station grounds. A new line was started which is called the station loop line. Other reroutings were established Sunday. These reroutings are the result of study by the members of the board of control, and were suggested by them to the receivers, who issued the order for the rerouting. The new schedules had to be approved by the City Council, and this formal action was taken before the station was opened.

The subject of handling mail in and out of the new station was not decided upon until Oct. 29, when the Metropolitan Street Railway and the Terminal Company finally got together on the details of an agreement for tracks for mail cars on the station grounds.

The Metropolitan Street Railway will probably use a temporary structure on or near the present Central Avenue bridge and viaduct, while the new viaduct is being constructed. This structure is part of the elevated railway system and provides a shorter route than the surface line between Kansas City, Kan., and Kansas City, Mo. Efforts had been made to induce the company to use the long inter-city viaduct, over which street cars have not been run for several years. It is reported that an interurban line may possibly use the inter-city viaduct.

An interesting feature of the rerouting in Kansas City is that the Independence line of the Metropolitan Street Railway will run on Twelfth Street to and through the business district. This is the first time that Twelfth Street, one of the main east and west arteries, has ever carried any other than the Twelfth Street car line, and it is the only downtown street that, except for a block or so, has been devoted to a single line. This routing puts the Independence cars through the south edge of the office and shopping district, while most of the non-Metropolitan interurbans pass through the office and shopping district north and south.

PUBLIC RELATIONS IN OKLAHOMA

The following editorial complimentary of the Oklahoma Railway, Oklahoma City, Okla., was published recently in the *Daily Oklahoman:*

"Hundreds of visitors during the State Fair period have had occasion to appreciate the kindly courtesy of street car men. Motormen have been careful to watch for belated, hastening passengers and have not followed the Eastern custom of 'failing to see' some breathless runner only a short distance out of line.

"Implicit confidence has been reposed by scores and scores of passengers in the street car conductors of Oklahoma City's lines, and they have not been betrayed. They have relied upon the car men to notify them when they reached certain streets, to direct them how to get to various points, to inform them of this and that, which, in reality, is no part of the conductor's duty except in the first-named instance.

"Little neglect or forgetfulness has been apparent on the part of conductors during this rather strenuous period, and Oklahoma City owes quite a debt of gratitude to the street car men for assisting in impressing upon strangers this city's reputation for hospitality. Politeness and acts of accommodation pay. And because some have been thoughtless of the courtesy extended them by the street car men we take this occasion publicly to express appreciation of it."

Following the publication of the editorial the company through George W. Knox, vice-president and general manager, caused the following notice to be posted:

"ATTENTION BOYS!

"Does It Pay to Be Courteous?

"Here is an unsolicited editorial which was in this morning's *Oklahoman*, and is a direct result of our talks on courtesy in our trainmen's meetings and your response and efforts toward promoting courtesy and good-will to the patrons of this road.

"You should appreciate this editorial and I want you to know that this company appreciates it and your efforts in bringing about conditions which prompted the writing of this article, as it means so much to you and to the Oklahoma Railway, namely, to have the kind consideration and friendly feeling of the people with whom you are dealing.

"Keep up the good work and still greater reward will be yours."

CLEVELAND RAPID TRANSIT RAILWAY FILES $50,000,000 MORTGAGE FOR RECORD

A mortgage for $50,000,000 in favor of the Central Trust Company, New York, was filed at Cleveland, Ohio, on Oct. 23 by the Cleveland Rapid Transit Railway. This is the first step toward financing the proposed underground railway in the city. W. R. Hopkins, president of the company, said that the present ordinance calls for the construction of a line east from the Public Square and another west, as soon as the high-level bridge across the Cuyahoga River will permit operations. The first funds derived from the sale of the bonds secured by the mortgage will be devoted to the construction of these two lines. Stock of the company will also be sold and the proceeds devoted to the same purpose.

It will be necessary to have the franchise ordinance amended in order to carry out the plans. It is now proposed to make the tube 12.6 ft. high and 21.8 ft. wide instead of 8 ft. high and 13.2 ft. wide, as originally designed. It will accommodate surface and interurban cars, under the modified form, while as originally designed only the Du Pont type of underground car could be operated. Two of the interurban lines leave the city on the east side and two on the west. While definite statements have not been made in regard to them, the subway would undoubtedly offer them an excellent means of increasing their running time between Cleveland and other points.

W. F. Thompson, president of the City Council, favors a liberal franchise to the company, but believes that an entirely new grant should be made if the city is to be asked for changes in the original grant. He also believes that the company should furnish the city with a certified check for a substantial amount as a guaranty that the company will begin the work within a specified period and will comply with the terms of the ordinance in other respects. The first grant to the company was made under the administration of the late Tom L. Johnson in 1908. Later the ordinance was modified to give the company an extension of time within which to commence work. Other changes will now be requested.

DECISION OF PITTSBURGH ARBITRATORS

The decision of the arbitrators in the wage dispute between the Pittsburgh (Pa.) Railways and the motormen and conductors employed by the company was handed down late on Nov. 2. An adverse decision to the employees was made by the arbitrators, Congressman Stephen G. Porter, representing the men, dissenting from the joint opinion of Judge Joseph Buffington of the United States Circuit Court of Appeals, who was the third arbitrator, and Attorney James C. Gray, representing the company.

The employees wanted a flat wage rate of 35 cents an hour instead of wages based on the length of service. The present rate is 23½ cents an hour for the first six months, 26 cents for the second six months, 26½ cents for the second year, 28 cents for the third year, 29 cents for the fourth year and 30 cents an hour for the fifth year and thereafter. All the points of contention of the employees were refused. In the matter of Sunday pay, both the company and the employees were refused, the company having asked for a decrease and the employees for an increase in wages. The present Sunday wage rate will be continued.

The wage question has been up for settlement in Pittsburgh since last spring.

NEW HAVEN DIRECTORS INDICTED

Twenty-one directors, past and present, of the New York, New Haven & Hartford Railroad were indicted on Nov. 2 by the Federal Grand Jury for conspiracy to monopolize interstate commerce by acquiring the control of practically all the transportation facilities of New England. This is the result of the government investigation of New Haven affairs which has been in progress for more than a year and which, as regards the civil aspect of the case, was settled by a decree to which both sides agreed before it was presented for Judge Mayer's signature two weeks ago. Charles S. Mellen, formerly president of the company, who was the chief witness before the Grand Jury and thus gained immunity, was not indicted. The defendants named in the true bill were William Rockefeller, George Macculloch Miller, Charles F. Brooker, William Skinner, D. Newton Barney, Robert W. Taft, James E. Elton, James S. Hemingway, Lewis Cass Ledyard, Charles M. Pratt, A. Heaton Robertson, Frederick F. Brewster, Henry K. McHarg, Edward D. Robbins, Alexander Cochrane, John L. Billard, George F. Baker, Thomas De Witt Cuyler, Theodore N. Vail, Edward Milligan and Francis T. Maxwell. Nearly fifty men, some of whom are now dead, were mentioned in the indictment as having conspired with the twenty-one, although they were not indicted. The indictment was handed up in the morning to Judge Foster, who was sitting temporarily in the Federal District Court in New York, Assistant Attorney General Frank M. Swacker,

R. L. Betts, and James W. Osborne were present for the government, and Mr. Osborne asked that bench warrants might issue immediately for the defendants. This was ordered by the court, and the federal officials immediately began to notify the defendants who were in the city. On Nov. 6 only three of the indicted men had not yet appeared before the court to enter pleas. They were Messrs. Cuyler, Elton and Brooker. Interest centered in the appearance of William Rockefeller on Nov. 5.

State Utilities Board Appointed in Maine.—Governor Haines of Maine on Oct. 30 appointed Benjamin F. Cleaves, Biddeford, William B. Skelton, Lewiston, and Samuel W. Gould, Skowhegan, as member of the Board of Public Utility Commissioners created by a new law. All three of the men are lawyers.

Barcelona Development Plans.—It is reported that the construction work of the Barcelona Traction, Light & Power Company remains at a standstill because of the inability of the French bankers to continue payment upon securities underwritten shortly before the war broke out. It is said there is a market in Spain for all the power the company can produce, even under present conditions. The main construction of the company, however, is hung up because of the lack of funds.

Another Pittsburgh Subway Franchise.—Another subway ordinance has been presented to the City Council of Pittsburgh, Pa. The new measure provides that the downtown terminus of the proposed subway be at least as far west as Ferry Street and the eastern terminus as far east as Kelly Street. The route would be through the Oakland district, or, if not, there would be a spur run into Schenley Park and near-by territory. The ordinance has been referred to the committee on surveys.

Communication of Toledo League to the Council.—The City Council of Toledo, Ohio, received a communication from the Municipal Ownership League recently urging that all negotiations with the Toledo Railways & Light Company be abandoned and that legislation be enacted looking toward the acquirement of the company's property by the city. The league contends that the remaining franchises held by the company expired on Nov. 7, 1914. The letter has been referred to the committee on railroads and telegraphs of the Council for consideration.

Loyal Railway Purchase Negotiations.—A committee comprising Councilmen Cooley, Haas, Hesketh, Marble and Lundy and Superintendent of Public Utilities Valentine of Seattle, Wash., has been appointed by the city utilities committee of the City Council to confer with Harry Whitney Treat in regard to purchasing the Loyal Heights Electric Railway, owned by Mr. Treat. The property has been offered to the city for $80,957, which Mr. Treat asserts he has invested in the property. Mr. Valentine has estimated that the line could be duplicated for $53,366. If the City Council should decide to purchase the line it will be made an adjunct to the Seattle Municipal Railway.

Mexican Operators Embarrassed.—The syndicate, headed by Dr. F. S. Pearson, New York and London, which owns the electric tramways in the city of Mexico and the hydroelectric plant at Necaxa, and the lighting and power system of the capital and other cities, has been greatly embarrassed in the conduct of its business by the attitude displayed toward its interests by the Constitutionalist government. A few weeks ago when the demand of the Mexican employees of the tramways for a 100 per cent increase in wages was not granted, General Carranza ordered the federal district authorities to take over and operate the property pending a settlement of the trouble between the men and the management. No settlement has yet been reached and the government is still operating the lines.

Public Relations in Las Vegas.—W. P. Southard, manager of the Las Vegas (N. M.) Transit Company, has been unanimously re-elected president of the Commercial Club of that city. In commenting upon the election, the Las Vegas *Optic* states that "during the twelve months in which he has been at the head of the Commercial Club, Mr. Southard has accomplished more for the club than has anyone ever before during the period of the club's existence." In placing Mr. Southard in nomination, speakers of the evening gave him unstinted praise for his great work in promoting the interests of the organization. It is the policy of the Federal Light & Traction Company, which controls the property at Las Vegas, to urge its representatives to take an interest in the affairs of the cities in which the company operates.

Intra-Mural Railway at Exposition Under Construction.—A shipment of rails and ties for the miniature railway at the Panama-Pacific Exposition, San Francisco, Cal., has arrived on the grounds and about fifty men are at work grading and laying track. Although the locomotives and other equipment, except in the interior of the cars, as described in the ELECTRIC RAILWAY JOURNAL of June 13, 1914, are just one-third standard size, the system is expected to handle a great volume of traffic across the grounds. The gage is 19½ in., and cars 20 ft. long have been built with seats for twenty passengers. With ten cars per train and eight trains in operation, the maximum operating capacity of the system will be 1600 passengers. Conforming to speed regulations, the trains will make about 10 m.p.h. between stations, of which there are to be seven, including three terminals, for which elevated tracks, train sheds and turntables are being built.

City Checks Chicago Elevated Railroad Valuation.—A new appraisal of the Chicago elevated railroad properties, ordered by the local transportation committee of the Chicago City Council as a preliminary to reopening negotiations for a merger of the surface and elevated lines, is being conducted by the department of public service. In connection with this valuation Montague Ferry, commissioner of public service, has undertaken to determine the value in dollars and cents of the franchise of the elevated railroads. In all its dealings with the traction companies, the local transportation committee has never recognized franchise or other intangible values. In a statement regarding what the franchise value might be, Commissioner Ferry said that he had as yet not reached a definite conclusion. It is understood that as soon as these valuation figures have been completed negotiations will again be resumed for the merger of the elevated and surface lines with a one-city, one-fare offer as the basis.

St. Louis Bridge Franchise.—Mayor Kiel of St. Louis says that he will sign the repeal of the Lorimer-Howe franchise which the City Council has already passed and which the House of Delegates is now about to approve. "Jep" Howe, a former "boss" in St. Louis has admitted to W. C. Niblack, receiver for the LaSalle Street Trust & Savings Bank, Chicago, William Lorimer's defunct banking institution, that he received $300,000 of the bonds of the Southern Traction Company as attorney's fees for assisting the passage of a franchise through the House of Delegates and the City Council of St. Louis and that the bonds were pledged when the LaSalle Street Trust & Savings Bank went into the hands of a receiver. Mr. Howe now demands the return of the bonds by the receiver. Three times the people of St. Louis have refused to vote a bond issue to build an eastern approach to the municipal bridge, on the grounds that no one company had an exclusive right to the use of the bridge.

Investment Bankers of America.—The third annual convention of the Investment Bankers' Association of America will be held at the Bellevue-Stratford Hotel, Philadelphia, on Nov. 12 and 13. President George B. Caldwell will call the convention to order at 10 o'clock Thursday morning. A considerable part of that day will be devoted to reports of officers and committees. In the afternoon Howard S. Graham, president of Graham & Company, Philadelphia, will discuss the 5 per cent railroad rate case and Sir George Paish will talk on the English moratorium. Friday will be devoted to a number of important addresses by prominent financiers, the election of officers closing with a banquet. The addresses include: "An Equitable Solution of Our Public Utility Problems," by Andrew J. Frame, president of the Waukesha National Bank, Waukesha, Wis. "Railroad Maintenance and Depreciation," by William H. Coverdale, president of William H. Coverdale & Company, Inc., New York, and "The Federal Reserve Bank and Its Effect on Investment Securities," by H. Parker Wills, secretary of the Federal Reserve Board, Washington, D. C.

Bay State Street Railway Wages to be Arbitrated.—Negotiations between the employees of the Bay State Street Railway, Boston, Mass., and the company have resulted in an agreement to arbitrate wages. The usual method of selection will be followed, the company and the men naming one arbitrator each, the third being chosen by the two thus named. The company offered the platform men an increase of half a cent an hour for the first year under the desired new agreement and an additional half cent an hour for the second year, the graduated scale, which requires a man to work seven years to obtain the maximum rate, remaining the same. A further guarantee was offered to extra men of at least a five-hour work day. The present scale of wages is 24 cents an hour for the first year, 25 cents for the second, 26 cents for the third to fifth years inclusive, 27 cents for the sixth and seventh years, and 28 cents thereafter. The present agreement expired on Oct. 1. In the negotiations preceding the making of the arbitration agreement, the company refused to reduce the hours of the shopmen and the employees in other departments from ten to nine a day. The company also refused to grant shopmen an increase in wages at this time.

Public Relations in Meridian.—The Meridian *Star* recently contained an illustrated description of the activities of the Meridian Light & Railway Company, Meridian, Miss. The sub-title to the article was "A public service corporation that has won the good-will and consideration of the community in which it is operated through its liberal, fair and equitable treatment of the public and efficiency of its service in every department. An important factor in the growth and progress of Meridian, the metropolis of Mississippi." The article concluded with the following tribute to the management of the company: "A distinguishing characteristic of this operation is the recognition which it constantly manifests, of its identity with the city in which its operations are conducted and the unity of interests that subsists between it and the people whom it serves. No movement of any kind is inaugurated in the name of progress for material, moral or social advancement that it does not give hearty and generous support, while its service is constantly laid under contribution in behalf of some worthy cause or occasion that needs it. It is, essentially, and logically, a city builder, it realizes that its profits and prosperity depend upon the growth of the city and a constant increasing demand for the utilities which it supplies. Moreover, it understands that its best asset lies in the good-will and the approval of this public, and that to secure these an efficient and adequate service in every department of its activities must be maintained, while justice, consideration and right treatment must govern its relations with every patron."

PROGRAM OF ASSOCIATION MEETING

Central Electric Railway Association

The program has been announced for the meeting of the Central Electric Railway Association, which is to be held in Fort Wayne on Nov. 19 and 20. This meeting will be preceded by a meeting of the executive committee on the evening of Nov. 18. The meeting of the Central Electric Traffic Association will be held on Nov. 19. The program for the meeting of the Central Electric Railway Association is as follows:

Nov. 19

Report of standardization committee, by R. N. Hemming, chairman, superintendent of motive power of the Union Traction Company of Indiana, Anderson, Ind.

Paper, "Treatment of Ties or Wood Preservation," by W. F. Goltra, president of the W. F. Goltra Tie Company, Cleveland, Ohio.

Paper, "Inter-Mating Tool-Steel Pinions with Untreated Gears," by E. S. Sawtelle, assistant general manager of the Tool Steel Gear & Pinion Company, Cincinnati, Ohio.

Nov. 20

Paper, "Interurban Headlights," by J. W. Esterline, president and general manager of the Esterline Company, Indianapolis, Ind.

Paper, "Oxy-Acetylene Welding," by H. E. Smith, engineer of the Prest-O-Lite Company, Indianapolis, Ind.

Paper, "Selection of Railway Equipment," by J. F. Layng, engineer of the General Electric Company, Schenectady.

Financial and Corporate

CONDITION OF THE COUNTRY

Many auspicious events have marked the operations of the financial and money markets during the last week. The deficiencies in cash reserves registered each week since the outbreak of hostilities have been wiped out, and sterling exchange rates have actually been brought down below the gold export point. Moreover, with the end of the British moratorium outstanding credits in our favor have been released and the exchange market is again in equilibrium. These are not the only causes of optimism, however, on the part of commercial representatives. The promised opening of the federal reserve banks on Nov. 16 will place at the command of industry and trade hundreds of millions of dollars. Foreign orders for American products continue to pour in, and large credits have been established with New York bankers by foreign interests to support their purchases. Exports, while much behind last year, are showing monthly increases, and a balance of trade in our favor is being accumulated which should relieve the effect upon foreign-held American securities when the stock markets open.

An interesting analysis of this whole situation, although at first glance pessimistic, has just been made by Wm. Morris Imbrie & Company, New York. According to this banking house, a decline in business in September as compared to the corresponding period for last year, was shown in the following cases: New buildings, total bank clearings, bank clearings excluding New York, failures, imports and exports of merchandise, balance of trade, railroad earnings, New York deposits, new securities issued, gold production and idle cars. Offsetting this poor showing, however, are the facts that in commodity prices and New York bank loans there was an active business as compared to last year, that crops and production have increased and that railroad earnings, money in circulation, New York bank loans and deposits, exports and the balance of trade exhibit more favorable results for September than for August of this year. These increases for September may be taken as indicative of the more extended improvement that took place during October and will develop even more so now. The condition of business is still not satisfactory, but there is at least ground for increased cheerfulness.

STABILITY OF UTILITY EARNINGS

S. R. Bertron Finds Gratifying Stability of Such Earnings Under Conditions Caused by the European War

S. R. Bertron, of Bertron, Griscom & Company, New York, in speaking of present conditions to a representative of the ELECTRIC RAILWAY JOURNAL, said that the stability in earnings of public utility corporations is a gratifying, although not an unexpected, element in the situation.

"We believe that public service company securities are the best that we can offer to our customers where the companies themselves have good franchises and are well managed," said Mr. Bertron. "They supply public necessities at a minimum cost under special franchise requirements, and every dollar of revenue is received in cash. There is less shrinkage in income in properties of this character in bad times than in any others that we know. Even under the present depressed conditions the earnings of most electrical central stations and gas companies are ahead of last year, while street railways show only a very small shrinkage from last year, varying from 1 per cent to 4 per cent. Up to the present the lighting companies in which we are interested show an average increase in gross earnings over last year of about 6 per cent and the street railways about three quarters of 1 per cent. The net result is that, instead of showing a normal increase in business, public service companies as a whole show some increase, even though a small one."

Mr. Bertron, when asked about the effect of the conditions arising from the European war upon capital expenditures of public service properties, said:

"The companies which we represent spend normally about $7,000,000 annually in new capital. On account of the difficulty of raising new capital now, expenditures of this character are being made only in necessary cases. Just when this policy will change depends upon financial conditions here. It is not necessary to assume, and we do not conclude, that we shall need to wait until the end of the war before undertaking new financing. It is probable that before the war is over financial conditions will permit the resumption of something like normal extensions.

"As business becomes adjusted to conditions and as the new currency act produces the promised release of a large volume of funds, and as economies of the people generally begin to tell in increased bank balances, the result should produce more comfortable rates for money. There are indications now that we are gradually approaching that stage of the situation. The improvement of conditions in the South resulting from the extension of credits now promised by bankers to the cotton growers will be a material factor and a favorable factor throughout the country at large."

Mr. Bertron was asked how he regarded present conditions as compared with those experienced in 1907.

"I am not sure," he said, "but that public service companies are in better shape now for the reason that conditions which preceded the panic of 1907 were very different from the conditions which preceded the outbreak of the war this year. Prior to 1907 general business of this character had been exceedingly active and was so up to the time of the panic, and the companies were expanding in full expectation of a continuance of prosperity and favorable markets for securities. At this time, however, on account of the lessened activity in general business and the depression throughout the country, public service properties were not making normal extensions and improvements at a normal rate. Consequently their construction operations did not have to be curtailed suddenly to as great an extent as was the case seven years ago."

INTERVIEW WITH MR. SCOTT

Holton H. Scott, president National Electric Light Association and general manager Doherty Operating Company, New York, gave some interesting views on the business situation in an interview this week with a representative of the Electric Railway Journal. The operations of Mr. Scott's company extend over sections in all parts of the United States except the Pacific Coast, and it tries to keep closely in touch with general business conditions in the communities served. Mr. Scott said that the Southern States dependent upon the cotton industry directly feel present conditions more than do other parts of the United States, with the possible exception of the districts dependent upon the oil market, but conditions for both are reflecting the improvement resulting from the marketing of part of their products.

Mr. Scott had just returned from a trip to Oklahoma, Kansas and other Middle Western states. Except in certain parts of Oklahoma directly affected by the oil market, he found things normal. In fact, Kansas and the other largely agricultural states seemed to be very prosperous and the people were decidedly optimistic. In Ohio, where his company operates several public utilities, large steel works were under construction in Warren and Massillon when the European war broke out. In spite of this, however, work on these new factories has been continued without a break. Many of the manufacturing towns in Ohio are operating, at least up to this date, at their normal capacity. Mr. Scott spoke as if the greatest amount of pessimism seen by him was found in New York.

He said, referring particularly to lighting companies, that public utilities have been affected by present conditions. Yet there are so many fields for enlarging the use of gas and electrical energy that, even if the increment of increases is reduced, the general average gross and net earnings should continue to increase. Many central station companies are curtailing construction expenditures and endeavoring instead to increase their business without extending their lines and enlarging their power stations, which will eventually be reflected in renewed prosperity and increased sales of appliances by manufacturers and jobbers.

In conclusion, Mr. Scott said that he had had occasion during the last few months to come into contact with many heads of electric lighting companies, and these men, instead of being pessimistic, are confident that the present disturbed conditions are being rapidly readjusted.

ANNUAL REPORT

Boston & Worcester Electric Companies

The comparative statement of income, profit and loss of the Boston & Worcester Electric Companies, Boston, Mass., for the years ended June 30, 1913 and 1914, follows:

	1914	1913
Income:		
Dividends on Boston & Worcester Street Railway shares owned	$55,688	$50,625
Other income	15,349	19,057
Total income	$71,037	$69,682
Disbursements:		
Dividend of $1 per share on preferred shares, payable Jan. 1, 1914	$33,936	$33,936
Dividend of $1 per share on preferred shares, payable July 1, 1914	33,936	33,936
Miscellaneous expenses	1,063	1,388
United States income tax	651	......
Total disbursements	$69,586	$69,260
Surplus for year	$1,451	$422
Surplus brought forward	14,917	14,495
Surplus	$16,368	$14,917

The comparative statement of income, profit and loss of the Boston & Worcester Street Railway for the years ended June 30, 1913 and 1914, follows:

	1914	1913
Revenue from transportation:		
Passenger revenue	$638,212	$631,169
Mail revenue	452	451
Freight and express revenue	71,171	24,938
Miscellaneous transportation revenue	649	200
Total revenue from transportation	$710,484	$656,758
Miscellaneous revenue	6,452	12,180
Total revenue	$716,936	$668,938
Expenses of operation:		
For conducting transportation	$258,279	$209,853
For maintenance	128,459	133,802
For general expense	78,339	74,192
Total expenses of operation	$465,077	$417,847
Net revenue above operation	$251,859	$251,090
Interest on funded and floating debt	$120,693	$124,241
Taxes	46,669	47,971
Total	$167,362	$172,212
Net surplus for year	$84,497	$78,878
Dividends on preferred stock paid during year	$23,832	$23,687
Dividends on common stock paid during year	55,688	50,625
Total	$79,520	$74,312
Surplus for year after dividends	$4,977	$4,566

The gross earnings increased from $656,758 in 1913 to $710,484 in 1914, the largest increases being from $631,169 to $638,212 for passenger revenue and from $24,937 to $71,171 for freight and express revenue. The expenses for conducting transportation increased from $209,853 to $258,279 and general expenses from $74,192 to $78,339, while maintenance expenses decreased from $133,802 to $128,459. The chief maintenance items for 1914 were repairs to track and roadway and line, $63,110, and repairs to rolling stock and miscellaneous equipment, $54,514. The net revenue of the company remained practically constant, but taxes and interest decreased from $172,212 to $167,362, giving an increase in net surplus from $78,878 to $84,497. Dividends increased from $74,312 to $79,520, leaving a surplus for the year of $4,977, as compared to $4,566 for the year previous. The car-miles operated during the year amounted to 2,108,294 and the car-hours to 132,174.

Dick, Kerr & Company

The annual meeting of Dick, Kerr & Company, the British electrical manufacturers, was held in London on Oct. 15. The chairman said that the net profits, which two years ago were £3,000, had increased to £30,000 a year ago and for the past year were £45,000. The fiscal year ended June 30, so that the accounts for the past year showed no effect of the war. Originally the firm was a contracting one, but with the development of the electric tramway the construction of electrical apparatus had been undertaken. With the diminution of new tramway construction, however, the company had again taken up general contracting, large work done during the last year including the construction of a steam railroad in Portuguese East Africa and a reservoir for the Metropolitan Water Board. The company had recently a contract for the electrification of the complete suburban system of the London & South-Western Railway and the Manchester lines of the Lancashire & Yorkshire Railway. It was stated that certain departments, such as the contracting department, would be detrimentally affected by the war, as the construction of public works would be deferred. Other departments should be stimulated, and the company now did not have the German competition for electrical equipment. Claud T. Cayley, chairman of the board, was re-elected to the board at the annual meeting.

ANNUAL MEETING OF BOSTON ELEVATED RAILWAY

At the annual meeting of the Boston Elevated Railway on Nov. 2, Sydney Harwood, Newton, Mass., was elected a director in place of Charles P. Hall, resigned. In his annual report, President Bancroft pointed out that the cost per running foot of building the Cambridge subway was the lowest for all subways recently built in Boston. The most serious problem before the company in the year had been the demands of labor. As a result of the findings of the board of arbitration, published in the ELECTRIC RAILWAY JOURNAL of Jan. 15, 1914, operating expenses were increased by not less than $480,000, or about 2 per cent upon the capital stock. The increase dated from May 1, 1913, so that there was charged to surplus $53,000 as not being applicable to this fiscal year. On May 1, 1914, a second increase required by the award became effective, and another is due May 1, 1915.

Reference was made by Mr. Bancroft to the opening of the Boylston Street subway on Oct. 3, which reduced the surface running time on the round trip from Kenmore Street to Charles Street by 14.5 minutes. The construction of the Dorchester tunnel has proceeded as far as Dewey Square, but the opening of this route, with that of the East Boston tunnel extension in the West End, cannot now be determined. During the year the company added 3.77 miles of surface track, making its total trackage 514.76 miles. A new cut-off line to City Point, South Boston, from Dewey Square, was opened last spring, giving the company three double-track lines to this resort. The company has received all of the 175 new cars mentioned in the last report. Thirty-two stepless, prepayment, middle-entrance, vestibule articulated cars have been placed in service and forty-three more have been authorized. Work has been suspended on the elevated extension to Everett from Sullivan Square pending the approval of national and state authorities.

During the year the capacity of the Coolidge Corner substation was increased from 4000 kw to 6000 kw; a 2000-kw transformer was added to the Harvard power station and arrangements were made to extend the boiler house at the main generating plant in South Boston, to provide for four new boilers and also to build and equip a new 4000-kw substation near Andrew Square. An agreement was reached with the Edison Electric Illuminating Company of Boston for the interchange of energy in case of a surplus or need on either side, through a 9000-kva frequency changer set. The net cost of workmen's compensation insurance for the year is estimated at $55,849. The work of the company's safety committees has reduced the cost of insurance, and employees' accidents decreased 21.7 per cent during the year.

A brief report of the company for the fiscal year ended June 30, as presented to the Massachusetts Public Service Commission, was published in the ELECTRIC RAILWAY JOURNAL of Oct. 24. The total revenue passengers carried during the year were 343,181,049, an increase of 16,828,186, or 5.16 per cent for the year. The number of revenue miles run was 57,990,436 and the revenue car hours 5,406,132. The miles of track equipped with electric third rail system were 36.24 and the miles equipped with electric overhead system 488.409. The stockholders of record June 30 are divided geographically in number as follows: Massachusetts, 5055; other states, 576; Cuba, 1; British provinces, 21; Europe, 12; South America, 1; Asia, 1, or a total of 5667. Grouped by shares the sections rank as follows: Massachusetts, 216,101; other states, 20,877; Europe, 1164; British provinces, 616; Cuba, 25; Asia, 10, and South America, 1.

DETAILS OF COLUMBUS REFUNDING ISSUE

As noted in the ELECTRIC RAILWAY JOURNAL of Oct. 24, the Columbus Railway, Light & Power Company has been authorized by the Ohio Public Utilities Commission to issue its first refunding and extension sinking fund 5 per cent mortgage gold bonds to refund underlying bonds. This refunding is to be accomplished from time to time as the holders may agree, as follows: (1) For the $3,000,000 of first consolidated mortgage forty-year 5 per cent gold bonds of the Columbus Street Railway, dated July 1, 1892, an even exchange at face value. (2) For the $572,000 of first mortgage forty-year 5 per cent gold bonds of the Crosstown Street Railway, dated June 1, 1893, an even exchange at face value. (3) For the $409,000 of the first mortgage twenty-year 5 per cent sinking fund gold bonds of the Central Market Street Railway, dated Jan. 1, 1902, an even exchange at face value. (4) For the $300,000 of first mortgage 5 per cent gold bonds of the Columbus Edison Electric Light Company, dated April 1, 1899, an even exchange at face value. (5) For the $3,145,000 of first consolidated mortgage forty-year 4 per cent gold bonds of the Columbus Railway, dated Oct. 2, 1899, or as much as the Columbus Railway, Power & Light Company is unable with the consent of the holders to retire by issuing its 4 per cent prior preference stock, an exchange on the basis of $850 face value of the petitoner's first refunding 5 per cent gold bonds for each $1,000 face value of these Columbus Railway bonds. (6) For the $450,000 of first mortgage 6 per cent gold bonds of the Columbus Electric Company, dated Nov. 1, 1897, or as much as the petitioner is unable with the consent of the holders to retire by issuing its 6 per cent preferred stock, series A, an exchange on the basis of $1,100 face value of the petitioner's first refunding 5 per cent gold bonds for each $1,000 face value of Columbus Electric Company bonds.

The company was further authorized to issue: (1) An amount of $3,145,000 of its 4 per cent prior preference stock at par, to refund the first consolidated mortgage 4 per cent bonds of the Columbus Railway at face value from time to time as the holders of these bonds may agree, with the option to these stockholders to exchange the stock back at any time before Oct. 1, 1924, for the petitioner's first refunding 5 per cent gold bonds at $850 face value of the bonds for $1,000 face value of the stock; (2) an amount of $450,000 of the company's preferred stock, series A, at par, to refund the first mortgage 6 per cent bonds of the Columbus Electric Company at face value, as may be agreed.

It is provided by the commission, however, that the above stated authority to issue 4 per cent prior preference stock as well as to issue the bonds in refunding the outstanding 4 per cent bonds of the Columbus Railway is an alternative authority. In so far as any of the bonds of the Columbus Railway are refunded into the first refunding 5 per cent gold bonds of the petitioner, the authority granted to refund the bonds of the Columbus Railway into an equal amount of prior preference stock is to be of no further force. As regards the refunding of Columbus Railway bonds into prior preference stock, the same holds true, except that the Columbus Railway, Light & Power Company may in turn issue its first refunding 5 per cent gold bonds in exchange for the prior preference stock theretofore issued in refunding the Columbus Railway bonds as authorized, if the stockholders exercise their option on or before Oct. 1, 1924. The authority granted to issue the 6 per cent preferred stock, series A, or bonds in refunding the $450,000 of 6 per cent bonds of the Columbus Electric Company, is also a similar alternative authority.

City Light & Traction Company, Sedalia, Mo.—The City Light & Traction Company, which is controlled by the Cities Service Company, recently offered in Sedalia at par and interest $25,000 of secured one-year 6 per cent coupon gold bonds, par $100, dated Oct. 1, 1914. The notes are issued for improvements and are backed by $50,000 of the company's first mortgage bonds as security.

East St. Louis & Suburban Company, East St. Louis, Ill.—The East St. Louis & Suburban Company, registered at Camden, N. J., on Oct. 31 decreased its capital stock from

$14,000,000 to $1,000,000. The stock will now be divided into 600 shares of preferred stock and 9400 shares of common stock at $100 par.

Fresno (Cal.) Interurban Railway.—The Railroad Commission of California has issued a supplemental order authorizing the Fresno Interurban Railway to issue $86,000 of ten-year 6 per cent bonds at not less than 90, and 460 shares of capital stock, par value $100, at not less than 80. The proceeds derived from the sale of these securities are to be used for the construction of an electric railway between Fresno and Clovis, a distance of approximately 9 miles. The parties promoting this line have already signed bonus agreements amounting to more than $17,000. These bonuses and any others acquired will be placed in a special fund to be used in making up any deficits that may occur during the early years of operation. If after three years the company's earnings are sufficient to pay its bond interest, operating expenses and taxes, any surplus remaining in the fund will be held as a sinking fund for the redemption of the bonds. The previous order of the commission was noted in the issue of the ELECTRIC RAILWAY JOURNAL of Oct. 31.

International Traction Company, Buffalo, N. Y.—Henry Morgan has been elected a director of the International Traction Company to succeed T. DeWitt Cuyler.

Los Angeles & San Diego Beach Railway, San Diego, Cal.—The Railroad Commission of California has authorized the Los Angeles & San Diego Beach Railway to issue a sufficient amount of bonds to yield $250,000 in cash, the proceeds to be used for the electrification of the company's line, the improvement of its properties, and the payment of certain obligations due to E. S. Babcock. The company has also filed an application with the commission requesting authority to issue two promissory notes amounting to $11,000 at 7 per cent interest for the purpose of refunding other notes outstanding.

New York (N. Y.) Railways.—The Public Service Commission for the First District of New York has granted the application of the New York Railways for authority to purchase all the outstanding capital stock of the Twenty-third Street Railway (6000 shares of $100 each), but on the condition that the company, in issuing its thirty-year 4 per cent gold bonds not to exceed $2,100,000 in payment, provide for the amortization of the difference between the par value and the market value of such bonds. The company proposes to purchase 4305 shares immediately, and the remainder are to be acquired from time to time as arrangements may be made. The commission authorizes the purchase upon the following conditions: (1) That the bonds be delivered only to holders of the stock at the rate of $350 face value of bonds for one share of stock; (2) that no such bonds be issued except in exchange for such stock; (3) that the railway provide for the amortization of 22 per cent of the face value of all bonds so issued, this representing the discount on the bonds; (4) that it keep open until Dec. 31 its offer of $350 face value of bonds for one share of stock, and notify all stockholders of the Twenty-third Street Railway of the acquisition of the majority of the stock and of its willingness to acquire the remainder upon the same terms on or before a specified date, not earlier than Dec. 31, 1914, and (5) that the time in which the bonds are to be issued shall expire Jan. 31, 1915.

Ohio Service Company, Dennison, Ohio.—The Public Utilities Commission of Ohio on Oct. 14 issued a final order authorizing the Ohio Service Company to issue $929,808 of three-year convertible notes, bearing interest at 6 per cent payable semi-annually and convertible into mortgage bonds within three years after their date. These notes are to be transferred in full and final payment for the properties purchased under the authority of the commission, as follows: $70,000 in payment for the purchase of the street railway property of the Twin City Traction Company at Dennison and Uhrichsville; $400,000 for the purchase of the electric lighting, ice manufacturing and street railway properties of the New Midland Power & Traction Company, Cambridge, Ohio, and the line running from Cambridge to Pleasant City; $424,000 for the purchase of the electric lighting plant at Canal Dover, the electric lighting and steam-heating plant at New Philadelphia, and the electric lighting plants at Dennison and Uhrichsville of the County Electric Company; and $35,808 for the purchase of the transmission line now being erected by the Lafayette Light & Power Company in Coshocton, Cambridge, Dennison, Uhrichsville, New Philadelphia and Canal Dover. This order supplements those noted in the ELECTRIC RAILWAY JOURNAL of Jan. 3, June 27 and Oct. 10.

Pacific Gas & Electric Company, San Francisco, Cal.—The Pacific Gas & Electric Company recently announced that it would purchase and accept delivery, as of Oct. 31, at the lowest prices offered, of $2,500,000 of its one year 5 per cent gold notes maturing March 25, 1915. These notes are part of an outstanding issue of $7,000,000. Owners of these notes were invited to forward sealed tenders to the Bankers' Trust Company, New York, on or before Oct 27, the tenders to be exclusive of accrued interest. A committee consisting of representatives of the Bankers' Trust Company, Harris, Forbes & Company and N. W. Halsey & Company was to supervise the transaction and had the right to accept or reject any or all bids in whole or in part. The Railroad Commission of California on Oct. 23 authorized the Pacific Gas & Electric Company to renew a promissory note of $100,000 to the National Conduit & Cable Company, bearing 6 per cent interest and payable not later than Oct. 20, 1915.

Portland, Eugene & Eastern Railway, Portland, Ore.—The annual report of the Portland, Eugene & Eastern Railway for the fiscal year ended June 30, which was recently submitted to the Oregon State Railroad Commission, shows a profit on the electric lines and a large deficit on the steam line of the company. According to this report, the company owns 105.68 miles of line and operates under lease or contract 3.05 miles, a total of 108.73 miles. Capital stock outstanding amounts to $508,800; funded debt outstanding, $1,200,000; capitalization per mile of line, $16,061; investment for road and equipment, $4,253,070; per mile of line, $30,974; operating revenues, electric, $190,219; operating expenses, electric, $171,752; operating revenues, steam, $88,405; operating expenses, steam, $121,801; operating deficit, $14,929; passengers carried, 3,687,700.

Richmond & Henrico Railway, Richmond, Va.—The Virginia Trust Company, Richmond, Va., which was appointed receiver for the Richmond & Henrico Railway on June 3, 1913, sold this company's property on Nov. 5 to E. Randolph Williams, counsel for the Virginia Railway & Power Company, for a consideration of $700,000. The company has an authorized capital stock of $1,250,000 and $2,500,000 of first mortgage 5 per cent bonds. It was organized about four years ago as a competing company to the Virginia Railway & Power Company. The receiver was appointed following a default in interest.

San Joaquin Light & Power Corporation, Bakersville, Cal.—The Railroad Commission of California has authorized the San Joaquin Light & Power Corporation to renew certain promissory notes, aggregating $64,156, for such periods of time as the applicant may desire, provided the aggregate of such renewal does not exceed one year from the date of the order. The new notes are to be issued at full face value and at the rate of interest which is specified in the company's application.

Seattle (Wash.) Municipal Railway.—The total receipts of Division "A" and Division "C" of the Seattle Municipal Railway for September showed a decrease of $732 as compared to the revenues for the preceding month, according to Superintendent of Public Utilities Valentine. The Lake Burien line showed the greatest drop in revenues, the freight and passenger revenues for September being $1,277 as compared to $1,888 in August, a decrease of $611. It is expected that the decrease in receipts in the autumn, on account of lighter passenger travel with the retirement of campers and summer tenants, will bring greater loss. Members of the Council are considering the adjustment of the Lake Burien schedule so that one car will be taken off part of the day. It is estimated that the municipal railway property was operated at a loss of approximately $2,000 during the summer months.

United Railways of St. Louis, St. Louis, Mo.—The Missouri Public Service Commission has authorized the United Railway of St. Louis to issue $600,000 of 5 per cent bonds, the proceeds of which are to be used in taking up an outstanding issue of 6 per cent bonds of the St. Louis & Suburban Railway.

Washington-Virginia Railway, Washington, D. C.—A dividend of 1 per cent has been declared on the $1,378,300 of common stock of the Washington-Virginia Railway along with the usual semi-annual payment of 2½ per cent on the $1,000,000 of preferred stock. These dividends were both payable on Nov. 1 to holders of record on Oct. 19. On May 1, 1½ per cent was paid on the common stock.

DIVIDENDS DECLARED

Boston (Mass.) Elevated Railway, quarterly, 1½ per cent.

Connecticut Railway & Lighting Company, New Haven, Conn., quarterly, 1 per cent, preferred; quarterly, 1 per cent, common.

Detroit (Mich.) United Railway, quarterly, 1½ per cent.

Illinois Traction System, Peoria, Ill., quarterly, three-fourths of 1 per cent, common.

Lehigh Valley Transit Company, Allentown, Pa., 1 per cent, preferred.

Rio de Janeiro Tramway, Light & Power Company, Ltd., Rio de Janeiro, Brazil, quarterly, 1¼ per cent.

Sao Paulo Tramway, Light & Power Company, Ltd., Sao Paulo, Brazil, quarterly, 2½ per cent.

Tampa (Fla.) Electric Company, quarterly, 2½ per cent.

Washington-Virginia Railway, Washington, D. C., semi-annual, 2½ per cent, preferred; 1 per cent, common.

Traffic and Transportation

REROUTING CASE DECIDED

Decision by Commission in Important Buffalo Case—Company's Attitude Highly Commended

The public Service Commission of the Second District of New York has rendered its decision in the case which has been pending since October, 1911, regarding the complaint made to it about the rerouting of the Elmwood and the Hoyt Street cars of the International Railway, Buffalo. The commission has denied the petition with reference to the rerouting of the Elmwood line, and has approved a suggestion made by the company about the Hoyt Street cars as a satisfactory adjustment of the principal question. This suggestion in substance provides for a change in the route of the Hoyt Street cars, taking them across Allen Street and Day's Park to Main Street, and thence down Main Street and out Seneca Street to the easterly terminus of that line and returning over Main and Allen Streets, and also rerouting the Grand Street cars by bringing them across Tracy Street from the corner of West Avenue and Carolina Street to South Elmwood Avenue and thence downtown.

The International Railway changed the routes of its Elmwood and Hoyt Street lines in Buffalo, which had, for many years, given crosstown service from the west side of the city to and down Main Street, and thence to the railroad stations; the new routes of said car lines were taken over South Elmwood Avenue, Chippewa and Franklin Streets. This action was the cause of many complaints to the commission from property owners and business men on upper Main Street, who alleged that the changing of the routes worked great damage to upper Main Street interests; counter petitions and remonstrances from the area traversed by such new routes were presented to the commission urging that such new routes be retained. The whole service in Buffalo, and particularly on the so-called west side, was fully discussed, and the conclusion was reached that adequate service for the west side requires crosstown service to and down Main Street of some of the existing lines of cars.

The commission holds that, in the settlement of these questions, the right of the public to adequate, convenient and proper service is paramount to all other considerations; that there is no duty imposed upon either the railway company or the commission so to route the cars of the company that the property values and business conditions along such routes will be preserved or enhanced; that such considerations have no place in the decision which should be arrived at in the case, except as they bear directly upon the convenience and necessity of the traveling public; and that even such convenience and necessity must be controlled in large measure by the ability and facilities of the railway company to satisfy them.

In its syllabus of the case the commission says:

"It is the settled practice of this commission that a street railway has the first right and duty to route its cars in order to satisfy the necessary demands of the traveling public; and if it shall appear to the commission that such routing does not give ample and proper service which the public interests demand, then it is clearly the duty of the commission to change such routes accordingly, giving due consideration, however, to such ability and facilities of the railway company.

"When it appears that the cars of a street railway are carrying substantially all of those who would avail themselves of transportation over its lines in a certain territory, no matter what changes are made in the routes, and it also appears that there would be no substantial increase in income, the commission should hesitate in making an order for a new line of railroad or the increase in the number of cars then in use, which would add considerably to the operating expenses of the company; for it is equally the duty of the commission to conserve the interests of the railway while satisfying the demands of the traveling public."

Referring to the attitude of the company toward the whole proceeding the commission says:

"The attitude of the International Railway throughout this inquiry, and particularly at the present time, has been most helpful to the commission in its efforts to reach a proper decision in this case; and this is clearly shown by the communication, which was recently received by the commission from the president of the company, by which it appears that, after the lapse of so many years, during which time the chief question in this case has remained unsettled, the company announces its willingness to pave the way for the rerouting of the Hoyt Street cars, by putting the Grant Street cars in their place on South Elmwood Avenue and Franklin Street; all this involves the necessity of widening Tracy Street and building new tracks across that street from Carolina Street to South Elmwood Avenue, which will require the expenditure of about $40,000 by the company.

"The position of the respondent is very fair; indeed, the determination of the company, at the request of many of the interested parties, to make an outlay of so large an amount of money as will be required to reroute the Grant Street cars across Tracy Street, in order to help settle this controversy, is so public spirited that such action should receive more than passing notice from this commission; it should be commended; and the best commendation we can give is to approve of the suggestions made concerning the changes in the routes of the Hoyt Street and Grant Street cars, and use them as the basis for the decision in this case."

I. C. C. ACCIDENT BULLETIN

Accident Bulletin No. 51 of the Interstate Commerce Commission for the three months ended March, 1914, contained the following statement of collisions and derailments on electric railways for the period covered:

No.	Classes	Number	Number of Persons Killed	Injured	Damage to Road and Equipment and Cost of Clearing Wrecks
	Collisions:				
1	Rear	12	2	66	$3,422
2	Butting	3	1	11	2,025
3	Trains separating	..	..	..	......
4	Miscellaneous	9	..	19	1,895
	Total	24	3	96	$7,342
	Derailments due to—				
5	Defects of roadway	1	..	1	$10
6	Defects of equipment	2	..	10	1,850
7	Negligence of trainmen, signalmen, etc.	1	..	2	150
8	Unforeseen obstruction of track, etc.	1	..	4	150
9	Malicious obstruction of track, etc.	..	..	..	......
10	Miscellaneous causes	3	..	5	100
	Total	8	..	22	$2,260

	Total for same quarter of—				
	1913	65	5	383	$48,137
	1912	79	5	402	48,074
	1911	52	1	195	10,173

Inquiry Into Brooklyn Service.—The Public Service Commission for the First District of New York has decided to inquire into the service and equipment of the elevated lines included in the Brooklyn Rapid Transit System. The case will be opened with a hearing on Nov. 9.

Accidents in New York in September.—According to the summary of accidents for September, presented to the Public Service Commission for the First District of New York, it is shown that the number of accidents for the month totaled 6083, in comparison with a total of 6189 for September, 1913. The number of persons injured for the month was 4220, compared with 3995 for the year before; but the number of serious injuries declined from 222 in September, 1913, to 172 in September, 1914. The number killed was thirty for September in each year.

Southern Pacific Transbay Service at San Francisco.—Changes in dispatching via the Eighteenth Street line extension in Oakland, Cal., have made it possible to eliminate a transfer and give faster service between points in Oakland and San Francisco. The change was announced by J. C. McPherson, superintendent of interurban lines, and became effective on Nov. 2. Five trains per hour now run each way between Fourteenth Street and San Francisco boats, the running time to the ferry building in San Francisco now being thirty-five minutes.

Modification of Joplin Near-Side Stop.—The City Commission of Joplin, Mo., has modified the ordinance recently passed which required street cars to stop on the near side of crossings. Under the amendment, Charles Patterson, Commissioner of Public Utilities, may grant permission to stop cars on the far side. There are many waiting stations built by the railways in the outskirts of the city on the far sides of the crossings, and there are some crossings in the business district where boarding or leaving cars on the near side would be inconvenient for passengers.

Passenger Rates Increased in Central States.—In accordance with the decision of the Interstate Commerce Commission handed down last July, the railroads included in the Central Passenger Association will increase their rates effective on Dec. 1. In the future a charge of 2½ cents a mile will be made on interstate fares in the territory north of the Potomac River, east of the Mississippi River and west of Buffalo, Pittsburgh and Wheeling. Heretofore passenger rates have been based on an approximate 2-cents-a-mile basis, with the charge between stations calculated via the short route.

Joint Electric Railway and Steam Excursion.—Officials of the Fort Wayne & Northern Indiana Traction Company, Fort Wayne, Ind., and the New York, Chicago & St. Louis Railway, reached an agreement recently whereby through tickets were sold from Peru, Ind., and points east of Cleveland on Oct. 24. Tickets were also sold over the Fort Wayne & Northern Indiana Traction Company's line from Bluffton and points north to Cleveland on the same date. This is the first time in the history of the Fort Wayne & Northern Indiana Traction Company that an excursion has been run in conjunction with a steam road. Transfers were issued in Fort Wayne.

Service and Labor Questions in Lexington.—According to the opinion of James G. Denny, city solicitor of Lexington, Ky., if they feel that public safety demands such action the City Commissioners of Lexington have authority to compel the Kentucky Traction & Terminal Company to abandon the "front end only" system of handling passengers and return to the former system of one door at each end of the car. As to the differences between the union employees of the company and the company over the discharge of a motorman, Governor McCreary has named a second arbitrator to adjust the differences. Judge W. B. Smith, Richmond, Ky., who was named by the governor, declined to serve and on behest of both parties Governor McCreary now names Charles C. Bagby, Danville, as umpire.

Chicago & Oak Park Elevated Asks Fare Increase.—In a petition filed by Samuel Insull, receiver for the Chicago & Oak Park Elevated Railroad, Chicago, Ill., in the United States District Court, requesting that he be permitted to issue receiver certificates to pay the cost of elevating the tracks in Oak Park, he also requested the right to increase the fares between Oak Park and Chicago. This move on the part of the receiver is in accordance with the order of the court when it issued a temporary injunction restraining the Illinois Public Utilities Commission from enforcng its order on the elevated railroad to elevate its tracks in Oak Park. In this petition requesting an increase in the fare between Oak Park and Chicago it is stated that the competitors of the elevated line receive a 10-cent fare. It is estimated that if the fare was raised to 8 1/3 cents it would increase the earnings of the railroad $15,000, while if the fare was increased to 10 cents it would increase the earnings $20,000.

New Work Advertised in the Twin Cities.—A. W. Warnock, general passenger agent of the Twin City Rapid Transit Company, Minneapolis, Minn., prepared three full-page advertisements recently for use in the daily papers in Minneapolis and St. Paul. They were headed "Dale Street Car Line to Open," "New Street Car Lines to Open" and "Street Car Lines and Signs." The page headed "Dale Street Car Line to Open" appeared in the St. Paul daily papers. It not only showed the new lines built by the company this year, but reviewed all the work done by the company in St. Paul during 1914, the new lines, the extensions of old lines, the reconstruction of old car lines and new paving.

The page headed "New Street Car Lines to Open" gave the complete story of what the company has done in Minneapolis this year. The page "Street Car Lines and Signs" contained a complete list of all the company's lines, showing the signs carried by the cars and the routes of the cars. This is the first time the company has ever assembled such information about its lines for publication. The typographical arrangement of the pages was excellent.

City of Denver Cautions "Safety First."—The official publication of the city of Denver, Col., recently contained the following statement in regard to the need for care on the streets and the work that the police and the Denver City Tramway are doing in connection with the "safety first" movement: "The most frequently broken of the city's laws are the traffic rules. Therefore the police department has issued orders to all patrolmen and traffic officers to arrest all persons violating any portion of the law. The Denver City Tramway has co-operated with the department of safety along these lines, inasmuch as all employees of the company are required to secure the number of the machine of any offender, report same to the company, which in turn gives it to the police department. The tramway company has issued cards, which are placed in various conspicuous places throughout the city, pointing out the common violations which prove fatal in a great many cases. It may be well for any person owning an automobile or vehicle, if not in possession of a copy of the traffic ordinances of the city, to apply to the city clerk, room 102 City Hall, and secure one." This announcement was accompanied with reproductions of six drawings showing the results of carelessness in driving automobiles.

Monthly Commutation Increase Refused.—Contending that its present monthly commutation rate of $5, applicable to parties or associations of 100 individuals or more, between Napa and Vallejo, is insufficient to pay its proper proportion of expenses, the San Francisco, Napa & Calistoga Railway, Napa, Cal., petitioned the Railroad Commission of California for permission to increase such commutation rate to $6 per month. The commission held as follows: That the method used by the applicant of applying a car-mile basis to all items of expenditure irrespective of the relationship of the expense to the particular trains, the operating expense of which it is desired to determine, permits of such a number of inaccuracies as to make it impossible to reach a conclusion that the increase applied for has been justified; also in view of the fact that the applicant agreed to place in effect such a rate, provided that 125 commuters were secured, and that the Chamber of Commerce of Napa paid the deficit until the required number purchased commutation books, the application is denied without prejudice. Suggestions are made whereby applicant may effect economies by discontinuing a Sunday morning train and consolidating two of its daily trains running under a few-minute headway, without inconveniencing its passengers.

Transfer Decision Affecting Interurban Railways.—In a ruling just announced the Illinois Public Utilities Commission holds that under ordinances requiring interurban railways to give transfers to passengers for use over the city lines and vice versa, the transfer applies only to intra-urban traffic and cannot be applied on travel outside the city. The ruling is in the case of the application of the citizens of Wood River and Benbow City for a reduction of fare over the Alton, Granite City & St. Louis Traction Company's line into Alton. The citizens thought the fare ought to be reduced from 15 cents to 10 cents. The company answered that the fare to the city limits of Alton is now 10 cents and that the additional 5 cents represents the travel over the city lines. The commission fixes the fare at 12 cents from the down-town station, or 10 cents from the city limits, a transfer to be good to the city limits. The company can charge 3 cents a mile when passengers fail to purchase tickets. On the use of the transfer, the commission says: "The commission is of the opinion that all passenger traffic originating outside the city must be considered as interurban business which is not affected by the conditions of the present ordinances granted the respondent by the city of Alton. The commission is also of the opinion that the transfer privileges provided for in those ordinances relate to the intra-urban business only."

Personal Mention

Mr. Logan G. McPherson has resigned as director of the bureau of railway statistics at Washington, which is maintained by the steam railroads.

Mr. M. B. Knapp, formerly with the Republic Railway & Light Company, Youngstown, Ohio, has been appointed superintendent of the Hocking Power Company at Nelsonville, Ohio.

Mr. H. C. Harford has been appointed manager of the employees' stores of the Interborough Rapid Transit Company and the New York (N. Y.) Railways, to succeed Mr. F. H. Gard, resigned.

Mr. W. I. Frost has been appointed superintendent of station service of the New York, New Haven & Hartford Railroad, vice Mr. G. L. Graham, resigned to accept service with another company.

Mr. J. P. Mason has been elected president of the Woodstock & Sycamore Railway, Genoa, Ill., a consolidation of the Woodstock & Sycamore Traction Company and the Chicago, Waukegan & Fox Lake Railway.

Mr. P. E. Ryan has been elected vice-president of the Woodstock & Sycamore Railway, Genoa, Ill., a consolidation of the Woodstock & Sycamore Traction Company and the Chicago, Waukegan & Fox Lake Railway.

Mr. William B. McKinley, president of the Illinois Traction System, Peoria, Ill., who acted as campaign manager for Mr. William Howard Taft in 1912, in the election on Nov. 3 recaptured the seat in Congress which he lost two years ago.

Mr. Lewis W. Henry, who has been acting as right-of-way agent for the Indianapolis & Cincinnati Traction Company, Indianapolis, Ind., for the last two years, has been appointed traffic manager of the company to succeed Mr. Charles O. Warfel, now superintendent of the company.

Mr. R. S. Buck, formerly chief engineer of the Dominion Bridge Company, Canada, and previously with the engineering firm of Sanderson & Porter, New York, N. Y., has been appointed engineer of maintenance of way of the New York (N. Y.) Railways, to succeed Mr. W. T. Dougan, resigned.

Mr. A. R. Layman, safety appliance inspector for the State Public Utilities Commission of Illinois, has accepted an appointment with the Interstate Commerce Commission as a railroad inspector. Mr. Layman was appointed to the State Public Utilities Commission in 1909 by Governor Deneen, of Illinois.

Mr. Francis E. Baldwin has resigned as associate and chief assistant counsel of the State Public Utilities Commission of Illinois to become a member of the legal firm of Veeder & Veeder, Chicago. Mr. Baldwin was formerly judge of the County Court of Morgan County, Ill., and resided at Jacksonville.

Mr. Charles O. Warfel has been appointed superintendent of the Indianapolis & Cincinnati Traction Company, Indianapolis, Ind., to succeed Mr. Oscar Lively, who has become connected with the Michigan United Traction Company. Mr. Warfel started in as an agent on one of the lines of the company about ten years ago, and advanced to the position of traffic manager, also having charge of the purchasing department.

Mr. Travis H. Whitney was entertained at dinner recently by members of the staff of the Public Service Commission of the First District of New York at the Martinique in honor of his seven years' service as secretary of the commission. The chair was taken by Mr. James Blaine Walker, assistant secretary. Among others present besides Mr. Whitney and Mr. Walker were Chairman McCall, Commissioners Maltbie and Williams, ex-Commissioners McCarroll and Eustis and Judge W. L. Ransom of the City Court.

Mr. Oscar Lively resigned on Oct. 31 as superintendent of the Indianapolis & Cincinnati Traction Company, Indianapolis, Ind., to accept a position with the Michigan United Traction Company at Jackson, Mich. Mr. Lively started in the electric traction field as a motorman with the Indianapolis, Shelbyville & Southeastern Traction Company about eleven years ago. He was later made trainmaster and has been superintendent of the combined lines of the Indianapolis & Cincinnati Traction Company for the last three years.

Mr. H. W. Magruder was elected president of the Kansas Gas, Water, Electric Light & Street Railway Association at the seventeenth annual convention of that body held at Arkansas City, Ark., on Oct. 22, 23 and 24. Mr. Magruder was born in Edina, Mo., in 1880 and was educated in the schools at Pratt, Kan. In early manhood he entered the government railway mail service and later financed the electric plant at Liberal, Kan., and was made president of the new company, the Liberal Light, Ice & Power Company, in which capacity he has since continued.

Mr. William Seibert, superintendent of surface lines of the Brooklyn (N. Y.) Rapid Transit System, has been elected a director of the Coney Island & Brooklyn Railroad, which is now controlled by the Brooklyn Rapid Transit Company. Mr. Seibert is one of the best-known traffic men in the United States. He began his career as a conductor with one of the companies now included in the system of the Brooklyn Rapid Transit Company and has advanced through all of the intermediary transportation department positions to the one which he now holds.

Mr. Theodore P. Shonts, president of the Interborough Rapid Transit Company and the New York (N. Y.) Railways and former president of the Panama Canal Commission, contributed to the magazine supplement of the New York Sunday *Times* for Nov. 1 an article dealing with an elaborate plan suggested by him for the reconstruction of the Port of New York. He favors the plan of having the railroads pool their present properties. This accomplished, he says that the improvement as outlined by him could be carried out at relatively small expense.

Mr. Frederick W. Whitridge, president of the Third Avenue Railway, New York, N. Y., has answered Germany's appeals in a volume entitled "One American's Opinion of the European War." It will be recalled that Mr. Whitridge made a tour of the Continent just previous to the declaration of war and that he was in Scotland at the time hostilities were commenced. His opinion is that Germany is in the wrong and is following false gods. He noted a decided change in the people themselves just previous to the war, from the simplicity and modesty that formerly prevailed among them.

Mr. John P. Coghlan, who has been appointed receiver of the Northern Electric Railway, Chico, Cal., is manager of the claim department of the Pacific Gas & Electric Company, San Francisco, Cal. Mr. Coghlan was for many years a newspaper reporter in San Francisco and occupied his spare time with reading for the bar. Shortly after his admission to practice he was taken into the office of the city attorney of San Francisco under Mr. Percy V. Long and was entrusted with a most important line of work in which he gained distinction. He has been with the Pacific Gas & Electric Company now for several years.

Mr. James F. Hamilton, retiring general manager United Traction Company, Albany, N. Y., was tendered a complimentary dinner on Oct. 29 by the employees of the company, and was presented with a chest of silver as a token of esteem from the men. The presentation was made by Mr. Charles H. Armatage, formerly traffic manager of the company, who was in turn presented with a fur cap and fur gloves to match his other automobile apparel. As previously stated in the ELECTRIC RAILWAY JOURNAL Mr. Hamilton will in the future devote all his time and attention to the Schenectady (N. Y.) Railway.

Mr. William Osgood Morgan has been elected vice-president of the Empire United Railways, Inc., Syracuse, N. Y. Mr. Morgan is a New York attorney, who has been associated with electric railways for the last decade, during most of which time he was vice-president of the Sheboygan Railway & Electric Company, Sheboygan, Wis. For a time he was also an officer of the Greensboro (N. C.) Electric Company. Mr. Morgan has actively participated in the operation of railways, handling finances and legal matters connected with properties which have heretofore been under the management of Mr. Ernest Gonzenbach, now general manager of the Empire United Railways, Inc., and formerly president of the Sheboygan Railway & Electric Company. Mr. Morgan has contributed some interesting articles to the technical press, among them a summary of the Public Utility Law of the State of Wisconsin.

Mr. William T. Dougan has resigned as engineer of maintenance of way of the New York (N. Y.) Railways and in future will engage in the building and construction of business for himself in New York City. Mr. Dougan was graduated from Union College in 1892 and was at once made assistant to the chief engineer on construction of the Fonda, Johnstown & Gloversville Railroad, in which position he continued until he was made chief engineer of construction of the Herkimer, Ilion & Frankfort Electric Railway, now included in the Utica lines of the New York State Railways. In 1897 Mr. Dougan entered the employ of the Metropolitan Street Railway. He was engineer of construction of the underground conduit system until 1906, when he was made engineer of maintenance of way of the company, which has been succeeded by the New York Railways.

OBITUARY

John Kilgour, president of the Cincinnati (Ohio) Street Railway, which is operated by the Cincinnati Traction Company, is dead. Mr. Kilgour was born in Cincinnati in 1834 and was graduated from Burlington College in New Jersey. He entered business with his father in the wholesale grocery house of Kilgour, Taylor & Company, but left that firm to serve under his father with the Little Miami Railroad. Later he and his brother Charles became partners in the wholesale grocery firm of Neave, Brown & Kilgour. Subsequently he and his brother assisted in building the Pendleton & Fifth Street Railroad in Cincinnati. In 1873 the railways in Cincinnati, including the Pendleton line, were consolidated and Mr. Kilgour was elected a director. Nine years later he was elected president of the company. Mr. Kilgour was also interested in telephone development in Ohio and was for many years president of the local telephone company at Cincinnati. In addition he was interested financially in the Toledo, Bowling Green & Southern Traction Company and the Ohio Traction Company. Mr. Kilgour retired from active business about five years ago. Two years ago he resigned as head of the telephone company, but continued as president of the Cincinnati Street Railway up to the time of his death.

Charles O. Kruger, president of the Philadelphia (Pa.) Rapid Transit Company, died suddenly on Nov. 4. Mr. Kruger had apparently been in the best of health. About an hour before his death he left his office with several other representatives of the company to take luncheon at the Racquet Club. While they were walking from the dining room, Mr. Kruger collapsed and died almost instantly. Heart disease was given as the cause of his death. Mr. Kruger was born in Philadelphia on Dec. 14, 1864. His education was secured in the public schools of that city. He decided early to embark in a commercial business and received his first training in the office of S. & W. Welsh, who at that period were leading merchants and foreign bankers. One year later he became secretary of the company which took over all the arc light companies doing business in Philadelphia. He remained in this capacity until 1885, when he was made secretary and treasurer of the Penn Traffic Company, a corporation identified with the Cambria Steel Company. In 1893 he was chosen secretary and treasurer of the People's Traction Company and in 1895 he was made secretary and treasurer of the Union Traction Company, Philadelphia. Three years later he was advanced to the office of second vice-president and assistant general manager, being made vice-president and general manager in 1899. When the Philadelphia Rapid Transit Company, which absorbed the Union Traction Company, was formed in 1902, Mr. Kruger assumed the position of secretary. Subsequently he was elected vice-president and general manager. In 1909 he was advanced to the position of president. Mr. Kruger was a director of the Jenkintown National Bank, Jenkintown, Pa., and of the Northern National Bank, Philadelphia. He was a member of the Union League, Art, Racquet and Manufacturers' clubs of Philadelphia, the Huntingdon Valley Country Club and the Logan Country Club, and was an associate member of the American Electric Railway Association.

Construction News

Construction News Notes are classified under each heading alphabetically by States.

An asterisk (*) indicates a project not previously reported.

RECENT INCORPORATIONS

Lula-Homer Railroad, Lula, Ga.—Chartered in Georgia to build a 15-mile electric line from Lula to Homer. Connection will be made at Lula with the Southern Railway. Incorporators: S. S. Carter, W. A. Boling, E. E. Chapman and Joel Coffee, Lula.

***Quincy & Hamilton Electric Railway, Hamilton, Ohio.**—Chartered in Ohio to build an electric railway from Quincy to Hamilton. Capital stock, $525,000. Incorporators: Charles S. Carscallon, Charles D. Warner, Edward D. Parkelee, Charles H. Petsch, Warren H. Orr, Earl W. Wood and Robert R. Wallace.

FRANCHISES

***Bisbee, Ariz.**—The Board of Supervisors has been asked to grant a franchise to build an electric railway from Bisbee to Naco.

Los Angeles, Cal.—The Public Utilities Commission has approved the proposed franchise for an extension on Evergreen Avenue, Wabash Avenue, Zonal Street and Marengo Avenue, in Boyle Heights. The Council will call for bids for this franchise.

Clearwater, Fla.—H. A. Murphy and associates have received a franchise to build an electric railway from St. Petersburg to Tarpon Springs.

Methuen, Mass.—The Boston & Northern Street Railway has asked the Council for a franchise for a relocation of tracks in the east section of Methuen.

Southbridge, Mass.—The Worcester Consolidated Street Railway has asked the Council for a franchise to relocate its tracks in Southbridge.

Winnipeg, Man.—The Winnipeg Electric Railway has been instructed by the city to file plans for an extension in the northwest section of Winnipeg.

West Newton, Pa.—The West Penn Traction Company has asked the Council for a year's extension of time on its franchise in which to build an extension between West Newton and Hunker Station.

Montreal, Que.—The Montreal & Southern Counties Railway has received permission from the Council to connect its tracks with the tracks of the Grand Trunk Railway and the tracks of the Montreal Tramways Company in Montreal.

Dallas, Tex.—E. P. Turner, representing the Dallas Southwestern Traction Company, has received a second extension of time on its franchise from the County Commissioners to build the proposed electric line to connect Dallas, Glen Rose, Grand Prairie, Mansfield, Alvarado and Cleburne. The franchise was first extended to Dec. 31, and is now extended to June 30, 1915. [E. R. J., Aug. 29, '14.]

Mexia, Tex.—The Commercial Club has received a franchise to build an electric railway in Mexia.

TRACK AND ROADWAY

Huntsville & Florence Interurban Railway, Huntsville, Ala.—Preliminary arrangements are being made by this company to begin work soon on its line between Huntsville and Florence. Plans have been made for the necessary power, which will be secured from waterfalls in that section. Tracy W. Pratt, Huntsville, is interested.

Pacific Electric Railway, Los Angeles, Cal.—This company has placed in operation the new lines over the extension of Magnolia Avenue, which has been built with a view to its becoming a part of the interurban line ultimately to be built by way of Corona, La Habra and Los Angeles.

San Francisco (Cal.) Municipal Railway.—The Board of Public Works has awarded a contract to the United States Steel Products Company for track special work.

Connecticut Company, New Haven, Conn.—Plans are being made by this company to double track a number of its lines in New Britain.

Rome, Ga.—It is reported that the preliminary survey for the proposed interurban electric railway between Gadsden and Center, Ala., will be made by C. L. March, former city engineer of Gadsden.

Waycross Street & Suburban Railway, Waycross, Ga.—This company has placed in operation its extension to Hebardville.

Springfield, Ill.—The Illinois Public Utilities Commission has approved the issue by the Lee County Central Electric Railway Company of 1010 shares of common capital stock of a par value of $100 per share. The commission has also issued to the company a certificate of convenience and necessity permitting it to extend its present line from Middleburg, Lee County, to Rochelle, Ogle County. [E. R. J., Oct. 24, '14.]

Indianapolis, Ind.—The new Mars Hill line of Indianapolis has been placed in operation, the route of the West Indianapolis line being used to its terminal, thence over special tracks to Minnesota Street and on to Mars Hill, a distance of 2.66 miles from the downtown center of Indianapolis.

LaFayette & Northwestern Railway, LaFayette, Ind.—Offices have been established in LaFayette to direct the construction of this new line, and stakes have been driven to mark out the right-of-way. The railway will run northwestward from LaFayette to Montmorenci, thence north to Remington and Morocco, and thence northwest to Rensselaer, St. Mary's, St. Anne and Kankakee, Ill., where it will connect with the line of the Chicago & Interurban Railway into Chicago. O. L. Brown is the general manager, and he has just appointed Harry Shelhous as chief engineer. [E. R. J., Oct. 17, '14.]

Des Moines (Ia.) Railway.—It is reported that surveys are being made by this company on North Avenue in East Des Moines for a new crosstown line to extend from Waveland Park almost due east to the fair grounds. It will afford direct service between the residence districts of East and West Des Moines.

Covington, Ky.—The South Covington & Cincinnati Street Railway has received a perpetual franchise from the Council in Covington.

Louisville (Ky.) Railway.—Extension of the Market Street line of this company from the end of the track on Frankfort Avenue, out Haldeman Avenue and thence up the Brownsboro road is a possible developments, according to the response of President T. J. Minary, of the company, to a committee representing the Crescent Hill Forward Club.

Boston (Mass.) Elevated Railway.—Plans are being made by this company to extend its line from the present terminus on Playstead Road, West Medford, to Madison Street, on Playstead Road.

Cushing (Okla.) Traction Company.—Contracts have been awarded by this company to build a 13-mile line from Cushing to Drumright. The Cushing Construction Company was estopped from raising the appeal as regards this McAlester, Okla., general manager.

Ottawa & St. Lawrence Electric Railway, Ottawa, Ont.—Work has been begun by this company on the section of its line at Russell. The first division of the railway is to be 119 miles in length and will extend from Ottawa to Morrisburg and on to Beaudette with a branch line from Metcalfe to Russell.

Sudbury-Copper Cliff Suburban Electric Railway, Sudbury, Ont.—Surveys have been made by this company from Sudbury to Copper Cliff, 5 miles; grading has been completed from Sudbury 4.5 miles out, and about 6 miles of track has been laid through paved streets in Sudbury. Construction will be resumed in the spring on this line between Sudbury and Copper Cliff. J. H. Mackey, Sudbury, president. [E. R. J., Oct. 12, '14.]

Toronto Suburban Street Railway, Toronto, Ont.—That this company must build a line on Annette Street from Keele Street to Jane Street in Toronto, is the result of a decision in the Appellate Division at Osgoode Hall on Oct. 22. The company appealed from the order of the Ontario Railway & Municipal Board requiring a single track to be constructed on these streets. The court held that the company was estopped from raising the appeal as regards this order, but under an agreement between counsel there will be a stated case for the determination of the general question of law as to whether the Railway Board has power to direct the company to build tracks on a street on which, under the company's agreement, dated 1899, the company had an option to build or not.

Toronto, Ont.—Work on the Bloor Street civic line from Dundas Street to Quebec Avenue in Toronto will be begun by the city at an early date. It is stated that special legislation is not necessary.

Uxbridge, Ont.—It is stated that the Provincial Hydro-Electric Commission, in conjunction with the various municipalities, will begin the construction of the following lines this fall: Toronto to Unionville, 14 miles; Unionville to Uxbridge, via Vandorf, 25 miles; Unionville to Brooklyn through Markham; Unionville to Stouffville and Port Perry; also spur line from Vandorf to Newmarket. The cost per mile of the line from Unionville to Uxbridge is estimated at $27,650, including roadbed, buildings, bridges, roadways, etc.

Toronto (Ont.) Railway.—Arrangements have been made by this company and the city of Toronto for the reconstruction of the track on College Street in Toronto from Spadina Avenue to Lansdowne Avenue. The section between Spadina Avenue and Bathurst Street will be built at once.

Glenada, Ore.—The operation of an electric railway from Glenada to the lakes south of the Siuslaw to connect with a steamboat line across the lakes, is a project under way to be financed by Siuslaw capital in the development of extensive plans for this territory. A townsite has already been laid out on the south side of Tsiltcoos Lake. It is proposed to electrify the present narrow-gage tramway constructed by Porter Brothers, railroad contractors, from Glenada south 3 miles to Clear Lake which connects with Tsiltcoos and Long Lake. The railroad contractors will have no further use for the tramway and they have offered the line for a nominal sum to represent the sale value of the material minus the cost of tearing it down and shipping it away. Power is to be obtained, if the project is carried out, from the Florence Electric Company, which has wires already strung across the harbor and which supplies the town of Mapleton with current.• [E. R. J., Oct. 17, '14.]

West Penn Traction Company, Pittsburgh, Pa.—Plans are being considered by this company for a line between West Newton and Hunker Station.

Memphis (Tenn.) Street Railway.—This company is asked to consider plans to extend the Crosstown line north from Poplar Avenue and the Overton Park Avenue line out Overton Park Avenue to Evergreen. By extending the Crosstown line the Beale and Main line and the Jackson Avenue line could be tapped in the northeastern part of the city of Memphis.

***Brenham, Tex.**—Plans are being considered to build an electric railway in Brenham and through Washington County. Frank Eberle, secretary of the Brenham Young Men's Business Association, is interested.

Gulf, Freeport & Northern Railway, Freeport, Tex.—This company is asked to consider plans to extend its line through Rosenberg. Beginning at Freeport, the proposed line extends through Columbia, Damon's Mound and Fairchilds, and the surveying lines are now within a few miles of Rosenberg. Grading of some 20 miles from Fairchilds south has already been completed. D. A. Barr, Freeport, is interested. [E. R. J., Oct. 3, '14.]

***Dayton, Tex.**—Plans are being considered to build an electric line between Dayton, Houston, Beaumont and Liberty.

San Antonio, San Jose & Medina Interurban Railway, San Antonio, Tex.—Citizens of Castroville, La Costa, Rio Medina and Red Wing have raised a bonus of about $35,000 to aid in the construction of an interurban line to extend between San Antonio and the Medina dam, via San Jose, Kirk, La Coste, Castroville and other points. It is planned to begin construction of the line between La Coste, 25 miles west of San Antonio, on the Sunset division of the Southern Pacific Railroad, and the Medina dam within the next few weeks. J. G. Miller, 400 Swearingen Building, San Antonio, general manager. [E. R. J., Sept. 26, '14.]

Morgantown (W. Va.) Interstate Railway.—This company has awarded a contract to Joseph Vandergrift, New York, to build an electric line from Morgantown to Point Marion, Pa.

SHOPS AND BUILDINGS

Miami (Fla.) Traction Company.—Plans are being prepared by this company to build new carhouses in Miami.

Bay State Street Railway, Boston, Mass.—The company has opened a new passenger station on School Street in the Washburn Block in Brockton.

Kansas City, Clay County & St. Joseph Railway, Kansas City, Mo.—This company has recently erected an addition to its car shops and offices in North Kansas City at a cost of about $1,000. One of the new stations on the line is that at Camden Point, Mo., about half-way between Kansas City and St. Joseph. The station is of the company's special design, frame and stucco, and is arranged as a residence for the agent. The station also has a little store, to be operated by the agent. The cost of this station was $2,500.

New York Consolidated Railroad, Brooklyn, N. Y.—The Public Service Commission has extended the time within which this company will build a new passenger station upon its Myrtle Avenue elevated line at Cumberland Street and Myrtle Avenue in Brooklyn, from Oct. 1, 1914, to Jan. 31, 1915.

Chambersburg, Greencastle & Waynesboro Railway, Waynesboro, Pa.—Work has been begun by this company on the new addition to its carhouse on East Main Street in Waynesboro. The structure will be 40 ft. x 100 ft. and will be frame, with galvanized roof and sides. It is being built for the purpose of storing the summer cars and will have a capacity for twelve cars.

Ogden (Utah) Rapid Transit Company.—This company has awarded the contract for the new interurban passenger station on Twenty-fourth Street in Ogden to C. F. Dinsmore, Ogden. The contracts for the electric wiring and heating have not been awarded. This terminal will be erected for the joint use of the local company and the Salt Lake & Ogden Railway Company.

West Virginia Traction & Electric Company, Wheeling, W. Va.—This company has received a shipment of material for the construction of a large pumping station to be located at or near Majorsville. Plans are being made to build a new passenger station at Majorsville.

POWER HOUSES AND SUBSTATIONS

South Covington & Cincinnati Street Railway, Covington, Ky.—This company will install new substation equipment consisting of two 1500-kw synchronous rotary converters, six 525-kva transformers, two switchboards and accessories. All the apparatus will be furnished by the General Electric Company.

Interborough Rapid Transit Company, New York, N. Y.—This company will install new substation equipment, comprising two 4000-kw, six-phase commutating pole rotary converters, seven 1400-kva transformers and accessories. The contract to build all the apparatus has been awarded to the General Electric Company.

Nashville Railway & Light Company, Nashville, Tenn.—This company will place in operation in one of its substations a 500-kw motor generator set which was recently purchased from the General Electric Company.

Corpus Christi Railway & Light Company, Corpus Christi, Tex.—This company will add to its substation equipment a 200-kw, three-bearing synchronous motor-generator set of General Electric make with 8.5-kw exciter.

San Antonio Gas & Electric Company, San Antonio, Tex.—This company will place in operation new substation equipment consisting of a 1000-kw, six-phase commutating pole rotary converter, three 350-kva transformers and accessories. This apparatus has been purchased from the General Electric Company.

Monongahela Valley Traction Company, Fairmont, W. Va.—This company will place in operation new power plant equipment comprising three 1250-kw, a.c. generators and 100-kw motor-generator set. The contract for the apparatus has been placed with the General Electric Company.

Manufactures and Supplies

ROLLING STOCK

Chicago, Milwaukee & St. Paul Railway, Chicago, Ill., has ordered one 1500-volt 50-ton electric locomotive from the General Electric Company.

Interborough Rapid Transit Company, New York, N. Y., is having ten work cars built by the Magor Car Company.

Bolivian Rubber & General Enterprise Company, La Paz, Bolivia, a new line in that city, has placed an order for rolling stock with The J. G. Brill Company.

Shore Line Electric Railway, Saybrook, Conn., is expecting to purchase several new interurban cars with seating capacity of not less than fifty-two persons, to replace those recently destroyed by fire.

Wilkes-Barre & Hazleton Railway, Hazleton, Pa., has under consideration the purchase of five interurban cars and ten city cars, as well as six or eight freight cars. These cars will probably be of all-steel construction.

Dallas (Tex.) Consolidated Electric Street Railway has specified the following details for the thirty-five closed prepayment motor cars recently built by the American Car Company:

Seating capacity	40
Bolster centers, length,	19 ft. 2 in.
Length of body	20 ft. 6 in.
Length over vestibule,	39 ft. 6 in.
Width over sills,	8 ft. 3 13/16 in.
Width over all	8 ft. 7 5/16 in.
Height, rail to sills	32⅜ in.
Height, sill to trolley base,	8 ft. 10⅞ in.
Body	composite
Interior trim	statuary bronze and malleable iron
Roofing	Agasote
Roof	arch
Underframe	metal
Air brakes	West.
Axles	Brill
Bumpers	American
Cables	G.E.
Car trimmings	Dayton
Control,	G.E. type, M.K., double-end
Couplers	Tomlinson
Curtain fixtures	Cur. Sup. Co.
Curtain material	Pantasote
Destination signs	Hunter
Fare boxes	Johnson
Fenders	H.B.
Pinions	Tool Steel
Gongs	Wall Mfg. Co.
Hand brakes	Dayton, with Peacock improved drum
Heaters	Consol.
Headlights	Esterline
Journal boxes	Brill
Motors,	2 G.E. No. 201, outside hung
Registers	International
Sanders	Elec. Ser. Sup. Co.
Sash fixtures	O. M. Edwards
Seats	Hey. Bros. & Wake, reversible
Seating material	rattan
Springs	Brill
Step treads	American Abrasive Metals Co.
Trolley catchers	Keystone
Trolley base	G.E.
Trucks	Brill 39 E
Ventilators	American

TRADE NOTES

C. M. Paxton has resigned from the Peter Smith Heater Company, Detroit, Mich., to re-enter the operating field.

Nachod Signal Company, Inc., New York, N. Y., has received orders from the Lehigh Valley Transit Company for four automatic signals, Types CD and MD. Part of this equipment will be used for the Eighth Street Bridge in Allentown, Pa., which is one of the notable concrete structures in America.

John A. Roeblings Sons Company, Trenton, N. J., has received a $50,000 order for telephone cable from the New York Municipal Railway which will be used for the first of a progressive series of instalments of the telephone train dispatching system on the new rapid transit lines of this company.

General Electric Company, Schenectady, N. Y., has received orders for electrical equipment from the following electric railways: Boston (Mass.) Elevated Railway, forty MK control equipments; Springfield (Mass.) Street Railway, ten air-brake equipments; Dayton & Troy Electric Railway, Tippecanoe City, Ohio, ten GE-88, 40-hp form B split-frame railway motors; Worcester (Mass.) Consolidated Street Railway, ten air-brake equipments; Cincinnati & Columbus Traction Company, Cincinnati, Ohio, four GE-73, 75-hp railway motors.

General Railway Signal Company, Rochester, N. Y., has appointed M. Wuerpel assistant to president. S. G. Johnson, vice-president, will be in full charge of the sales department (which includes all branch and foreign office, commercial engineering, commercial inspection and contract installation business) reporting to the president and general manager and with headquarters at Rochester. All those in the sales department formerly reporting to the president and general manager will now report to and receive all instructions from Vice-President Johnson. This company has created a department of publicity and education. H. M. Sperry has been appointed as manager of this department, reporting to the president and general manager and co-operating closely with all departments.

ADVERTISING LITERATURE

MacGovern & Company, Inc., New York, has issued a catalog of its used electrical and steam machinery, including cars and car equipment.

Prepayment Car Sales Company, New York, N. Y., has issued a folder entitled "Blunders," which calls attention to the saving from blunders effected by equipping new cars or re-equipping old ones with prepayment platforms.

Lutz-Webster Engineering Company, Inc., Philadelphia, Pa., has issued a folder describing its compression wrenches, drill posts, compression ratchets, double-end sockets, no-set-screw lathe dogs, drill sockets and bridge and extension sockets.

Eugene C. Mills, chief engineer Sacramento Valley Irrigation Company, Willows, Cal., has issued a booklet describing the corrugated iron construction on the Sacramento Valley Irrigation project. American Ingot Iron is used in this construction.

J. D. Este Company, Philadelphia, Pa., has issued a folder illustrating the game of "Skee-Ball," which recently attracted so much attention at the A. E. R. A. convention at Atlantic City. The game may be readily used as a drawing feature for amusement parks reached by electric railways.

Goldschmidt Thermit Company, New York, has issued pamphlet No. 16, second edition, describing and illustrating the thermit process of pipe welding. Pamphlet No. 39, just issued, describes some recent improvements in methods and practice made by this company in its thermit insert fully-welded rail joint.

Fiber Conduit Company, Orangeburg, N. Y., has issued the third edition of its complete fiber conduit catalog. The catalog gives detailed and illustrated descriptions of this company's various types of conduit, including the socket joint, sleeve joint, Harrington joint, screw joint and "Linaduct" types. A number of photographs show several installations of this conduit.

SKF Ball Bearing Company, New York, N. Y., has issued a compact catalog on the SKF ball bearing as applied to electric railway service. Of particular interest is the company's installation of these bearings on the new stepless cars of the Third Avenue Railway, New York, after SKF bearings had made good in four years' service on the same railway's storage-battery cars. The booklet reviews the merits of the ball bearing from many angles, including that of energy and lubrication economies, shorter motor length, better maintenance of armature air gap and improved meshing of gearing.

Swedish Ljungström Steam Turbine Company, Ltd., Finspong, Sweden, has issued its first catalog describing its "Stal" steam turbines of the radial-flow type, especially adapted to the driving of generators. In these turbines the reaction principle has been applied, which is said to result in unusually good steam economy, reliability and saving of space. In elaborating the design of this turbine special attention has been devoted to the effect of hot steam on its components and arrangements have been made so as to avoid any unfavorable influence of varying steam pressure and steam temperature on the adjustment of the different parts. The expansion and contraction of the material may take place without altering either the centering and balancing of revolving parts or the clearance between revolving and stationary parts. Consequently the working safety of the turbine is insured both at high and low temperatures, and this turbine system can therefore be applied in conjunction with the highest steam temperatures and steam pressures that are obtainable with existing types of boilers and superheaters.

Electric Railway Journal

Published by the McGraw Publishing Company, Inc.
Consolidation of Street Railway Journal and Electric Railway Review

Vol. XLIV NEW YORK, SATURDAY, NOVEMBER 14, 1941 No. 20

THE NEW HAVEN INDICTMENTS

A recent issue of the Springfield *Republican* comments editorially on the indictment of the New Haven directors as follows: "The time when the dead past will be permitted to bury its dead in the matter of criminal conspiracy to monopolize commerce seems far away." This puts in a graphic and figurative manner a fact which puzzles railway managers and others and worries them too, namely, that the federal administration seems disposed to hold all directors during the period when the consolidations were effected as responsible for the alleged extra-statutory acts committed. The inquisitorial dragnet includes not only those who were directors during all or most of the period under consideration, but such men as Theodore N. Vail, Edward Milligan and others who served only a short time under the old administration. Without going into the merits and demerits of the New Haven case, which have already been considered at length in the public press and will soon be rehearsed in much greater detail, it would seem that if the constituted authorities for many years did construe the consolidations effected by the New Haven Railroad as acts in restraint of trade, an effort to bring criminal charges on this basis now is little less than persecution. The public as a whole in the states affected feel the same way, if the result of the elections last week in New England and the East generally are any criterion of their sentiments.

ELECTROLYSIS WITHOUT STRAY CURRENTS

We take pleasure in printing a very unusual article in this issue of the Electric Railway Journal on the subject of electrolytic corrosion. This article is by E. H. Scofield, engineer of power and equipment, and L. A. Stenger, chemist of the Twin City lines. The authors were led to suspect that electrolysis might be caused by currents self-generated in pipes, their suspicions having been aroused by apparent signs of such corrosion in localities where return currents from electric railways could not possibly have existed. Having circumstantial evidence to confirm their suspicions they proceeded in a scientific manner to reproduce the observed results by simple and convincing experiments. These have covered a long period of time, and the electric railway industry is fortunate in having available the data which have thus far been secured. The conclusions are entitled to great respect on account of the manner in which they have been obtained, and they will be the source of considerable comfort to many electric railway operators at whose doors have been laid the blame for all corrosion of pipe which occurred within a wide range surrounding their return circuits and upon whom the public has been inclined to fasten the entire burden of introducing expensive corrective measures. The results of the tests illustrate the importance of considering all aspects of a problem as complicated as that involved in pipe corrosion. We feel sure that the authors will feel repaid if the publication of the results of their work leads to constructive discussion of a complicated subject.

SPECIAL WORK STANDARDIZATION

In a recent communication to this paper from R. C. Cram, assistant engineer of way and structures Brooklyn Rapid Transit Company, attention was directed to the lack of standard specifications for track special work. Mr. Cram suggested that a study of this subject should be conducted by a committee of the American Electric Railway Engineering Association. Our recent studies have impressed upon us most forcibly the need for such action, not only with the object of standardizing design, but also of enabling competing manufacturers to bid on the same character of material and design. At present railway engineers cannot compare bids because each manufacturer furnishes his own design, which may or may not be best adapted to the service conditions. Consequently, the order must be placed either on a price basis, or because a certain design is favored, a state of affairs which must be very unsatisfactory to manufacturers and engineers alike. A committee which would prepare a set of specifications enabling them to obviate these difficulties would receive universal approval. Probably the most perplexing phase of the problem of standardizing track special work is the extent to which it can be carried without conflicting with local conditions or automatically exiling certain designs from the field of competition. We believe that the prevalent condition affords an excellent opportunity for constructive work without extending to the point where the standards could not be generally used. To accomplish the best results and at the same time to make such an analysis thorough, it seems proper that such a study should begin with the foundations and cover the size, spacing and arrangement of ties under typical layouts, from a simple turnout to a grand union. Even if the work of the committee for one year was confined to the foregoing suggestion, it would, no doubt, find a wide diversity of opinion and an abundance of data for analysis sufficient to warrant definite recommendations.

THE PUBLIC UTILITY DRAFT BILL

This week has seen the culmination of three years' work on the part of the National Civic Federation in the publication of its draft bill for the regulation of public utilities, which is abstracted elsewhere in this issue. In reality, from the time when in 1907 the commission on public ownership and operation issued its conclusion that effective regulation in this country was preferable to public ownership and operation, the thoughts of the federation have been directed toward the question of what constitutes adequate regulation which would be fair alike to the investor, the operator and the public. In 1911, the increase in importance of the matter led to the formation of the department on regulation of public utilities and the selection thereby of the executive council of nine to prepare a tentative draft of a model public utility bill. The first two years of the committee's activities were devoted to the compilation of data, now available in printed form, showing the composition, method of creation and precise powers of every public body charged with the regulation of public utilities in our various states. Having thus obtained a basis for intelligent study, the committee devoted a year to the preparation of a model statute to be used as a basis for uniform legislation.

When tentatively drafted, the proposed bill was laid before those who it was thought were most competent to assist in reducing it to its final form, but the result served to emphasize fully the complicated and difficult nature of the problem involved. While of the more than 300 sections of the bill only sixty were criticised by anyone, yet the differences of opinion on these sixty points arising from different points of view on the part of federation members and others made it impracticable for the federation to obtain any general concord on the subject. If the association had been a legislature, it would naturally have bent every effort to secure the judgment of the majority of its membership in regard to the bill. Under existing conditions, however, its only function is to publish the results of the investigation as they stand, with the hope that they will be useful in throwing various light upon the issues involved.

A bill of this character is essentially a compromise measure, not representing in all probability the exact views of any single member of the council. Its chief value lies in the fact that it strikingly portrays the still very incomplete state of public utility legislation. Actually, there are as many radical variations in the legislative acts authorizing these commissions as there are states. This itself is not surprising when we consider the extent of the changes from former ideas of American methods of government which are involved in commission regulation. It will probably take many years of painful experience before the proper status of the commissions and the extent of the powers which should be committed to them will be even approximately determined.

When the investigation of the National Civic Federation began, forty-three states had regulatory bodies, although some of these bodies had very limited powers. During the compilation of the draft bill a number of these states greatly increased the powers of their commissions, notably Massachusetts, Illinois and Pennsylvania, and now only three states, Delaware, Wyoming and Utah, have no commissions. This suggests the question of the extent to which any standard bill drafted now will be adopted. It is difficult to satisfy oneself that the same differences in point of view that rendered it impracticable for the National Civic Federation to adopt a truly model bill will not prevent state legislatures also from adopting uniform regulatory practices. The tenacity with which existing commissions are hanging on to their accounting idiosyncrasies in the face of the Interstate Commerce Commission uniform system is a pertinent example. We would not be understood as inferring that the work was not worth the effort, for any move toward standardization is praiseworthy. In view of the still experimental stage of public utility legislation, however, we believe that the bill in its immediate effects will be of value principally in calling attention to the points that are still devoid of a widespread, to say nothing of a universal and final, solution.

Although the bill purports to be in advance of existing legislation it has a number of serious defects. For instance, we are surprised that there should not have been better recognition of the frequent changes of commission personnel and that the term of office was not made at least ten or preferably fifteen years, instead of five, so as to make a commissioner's tenure of office more independent of politics. Again, while deliberate violations of commissions' orders and offences of moral turpitude should be punished, some of the penalties enumerated in the bill are excessive, such as accumulating fines of $5,000 per day for failure to file a report within a specified time or to make a specific answer to any question propounded by the commission; imprisonment for five years for wilfully destroying or mutilating accounts, records or memoranda prescribed by the commission, or failing to make full entries of all facts, and penal sentences for any public utility officer or agent who neglects to comply with every order of the commission. One can also well criticise the restrictions as to the issue of securities which limit them to the amounts necessary to the "performance of duty to the public" instead of to the fulfilment of the purposes of incorporation, thus preventing a company from creating such a valuable adjunct as a legitimate park property for increasing its income. Again, the bill excludes all municipal public utility enterprises from the jurisdiction of the commission except so far as the regulation of their accounts is concerned. In the conduct of public utility enterprises, municipalities are as liable to make serious errors as private companies, and if any machinery is to be established for public utility regulation, municipal enterprises should certainly be included in its jurisdiction. These are by no means all of the clauses to which exception might be taken but are cited to show some of the points where changes should be made.

TAKING UP THE SLACK IN INTERURBAN SERVICE

Recent first-hand experience with a well advertised interurban service which competes effectively with a steam railroad between terminals suggests that a good deal of lost motion remains to be taken up on not a few such properties before the full benefits of the facilities offered can be enjoyed. The case is typical. The line traversed by the through electric cars has earned a well deserved popularity for the punctuality of its service; the rolling stock is clean and comfortable; the schedule speed over the interurban right-of-way is about 30 m.p.h.; but the through running time is nearly double that on the strictly interurban section on account of the slow movement in the terminal cities.

This cause of delay is an old offender, but it is just as important a factor in deflecting travel to the parallel steam road as though it had never been heard of by the managements of the three companies over whose tracks the through cars run in making a complete trip. Few business men are willing to take two hours for a journey in the middle of the day that can be covered in an hour by steam, even though the latter may cost 30 or 40 cents more than the former. Constructive criticism may be offered along general lines, not so much with the idea of discovering new principles as with the hope of calling attention to certain requisites of good service which are sometimes overlooked even in these enlightened days. The probabilities are that interurban companies realize these essentials better than a good many of the city roads, but as the end of the line is the best place to take up the slack, no apology is offered for emphasizing the failure of not a few local companies to render that alert co-operation in handling through and foreign cars which makes such a vast difference in the patronage and consequently in their own receipts at the terminal ends of the road.

So far as is humanly possible, through interurban cars should have the right-of-way. That is to say, they should be scheduled so as not to be delayed to any greater extent than necessary, and they should not attempt to do a local business. This can be accomplished by running the cars on some limited stop plan such as that of making stops only for boarding passengers on the trip out of the terminal city and for discharging passengers during the trip into the terminal city. A study should be made of the possibilities of short-cut lines within the city, and the movement of the cars can often be expedited through the congested districts by greater attention to the problem of police traffic regulation and street inspection. Too often an interurban car receives no more consideration from the traffic police officers than a local car, yet the time lost in slowdowns and in "inching along" with uncomfortable jerks and frequent dead stops in the vicinity of busy corners is by no means inconsiderable. Stop-watch studies of factory processes have accomplished wonders in a reduction of time for operations, and a complete time analysis of controller movements in getting into and out of interurban terminal cities would show some surprising inefficiencies of car movement in more instances than a few. The time is coming when automobile traffic at street intersections will have to wait for the passage of the interurban car; when freight trains and switch engines will not be allowed deliberately to ignore the rights of an interurban car waiting to cross a steam railroad track; when single-track entrances into cities will give way to double track; when conferences will be held to see if interurban crews cannot make the entire run without change, just as they now often run an overlap of a mile or so on the foreign system if the meeting crew is behind time; when all crew changes will be made quickly; when loading and unloading stops at the terminal cities will be made in squares or streets wide enough to allow free movement of passengers, and when every possible effort will be made to get local cars out of the way of through service. A few minutes saved here and a few there will soon be effective in stimulating increased patronage and without any demand for excessive speeds on the intercity stretches.

TRAFFIC INSPECTORS BY EXAMINATION

The traffic inspector usually does not earn more per hour than the platform man. His actual earnings, however, are greater because he can work more hours with less fatigue. The position is also attractive as a step upward to better things. In selecting this noncommissioned officer of the electric railway army, the management usually places more stress upon a pleasing but firm personality and record of meritorious service than on seniority and education. On one large property after the candidate is chosen he is sent to the instruction department to familiarize himself with the duties of a conductor if he has been a motorman, or with the duties of a motorman if he has been a conductor. Thus he is equipped to deal with problems at either end of the car. As finishing touches he makes a fresh study of the operating rules before the last quiz by the superintendent of transportation.

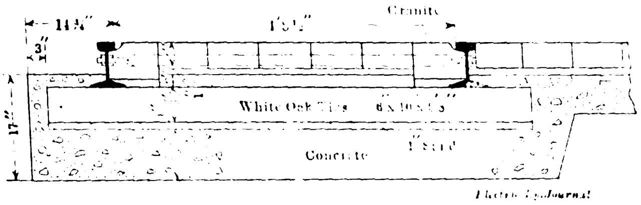
An entirely different principle for the selection of inspectors has been adopted by the Municipal Railways of San Francisco. In compliance with the law, the San Francisco Board of Public Works conducted on Oct. 31 a formal civil service examination for promotions from the platform to inspectorships. As recorded elsewhere in this issue, the examination allowed 85 out of a possible 100 points for accuracy in making out reports, local geographical knowledge and arithmetic. The low maximum of five points for experience is understandable because no man who had not seen at least three years' service was eligible, but only ten points were assigned for meritorious behavior.

The San Francisco examination should certainly bring forward the most literate of the men already employed and encourage the entrance of better educated men to electric railway service. We believe that the method would be greatly strengthened, however, if due allowance is made for personality. Such an allowance is not impracticable, as is shown by the experience of the Board of Education of New York City which makes such an allowance in conducting examinations for school teachers.

Renewing Rail On Twelve-Year-Old Ties and Foundations

An Interesting Piece of Track Rehabilitation on One of the Detroit United Railway's Principal Trunk Lines—In This Article the Character of the Work and the Facilities for Doing It are Described

Since the Detroit (Mich.) United Railway is recognized as one of the pioneers in the use of the sand cushion with concrete track foundations, no small interest will be attached to the rehabilitation of this type of construction after twelve years' service. Extremely heavy traffic, including both city and interurban equipment and averaging 63.6 cars per hour during the 365-day year, or an average of 1018 tons per hour during the same period, accounts in a measure for the depreciation of the track. Other items affecting the life of the track, in fact forming the real reason for rehabilitation, include the use of mechanical instead of cast-welded joints and a shallow-head 9-in. girder-grooved rail. On the other hand, when the fact is made known that only rail renewal was necessary at this time, the ties and track foundation being found in excellent condition requiring little or no expense to prepare them to receive the new rail, it will be seen that there really is some truth in the present-day term "permanent track construction."



D. U. R. TRACK REHABILITATION—CROSS-SECTION OF OLD TRACK

Prior to the beginning of actual reconstruction work, John Kerwin, superintendent of track, decided that although it was possible to obtain more service out of the old 90-lb. girder-grooved rail by making repairs, this would be done at the expense of the track foundations, which it was believed could be saved if the old rails and joints were renewed immediately. An investigation of the concrete foundation and ties indicated that both were as good as on the day they had been installed, except in a very few instances where extremely bad joints had crushed the concrete beneath the ties. Accordingly it was decided that by renewing the concrete in these spots, shimming the rail for slighter surface variations, and using a 7-in. 91-lb. T-rail in place of the 9-in. 90-lb. girder-grooved rail, thus providing additional wear life in the rail head, at least twenty years of additional track life could be obtained. Accordingly the reconstruction work of this main trunk line on Woodward Avenue was planned for this partial renewal, and after the work had been opened, that is, the old rail and paving surface removed, it was found that the decision based on the test was a good one, hence, the actual cost of rehabilitation would be greatly reduced.

CHARACTER OF OLD TRACK CONSTRUCTION

In 1902 the track department of the Detroit United Railway laid a double track on Woodward Avenue, using what was then termed this company's standard permanent track construction. This included an 8-in. concrete slab laid in the bottom of a prepared trench, and over this slab a 1-in. washed sand cushion was spread to receive the ties. These ties were white oak, 6 in. x 10 in. x 6 ft. 8 in. in size, spaced at 36-in. intervals. As mentioned before, the rail used was a 9-in. 90-lb. girder-grooved rail with eight-bolt angle-bar

joints. These rails were maintained at gage by 3/8-in. x 1¾-in. x 5-ft. 3-in. flat tie rods, installed at 10-ft. intervals. The depth of the rail allowed 4 in. of concrete over the surface of the ties, over which the 1-in. sand cushion was spread to receive a vitrified-brick pavement surface.

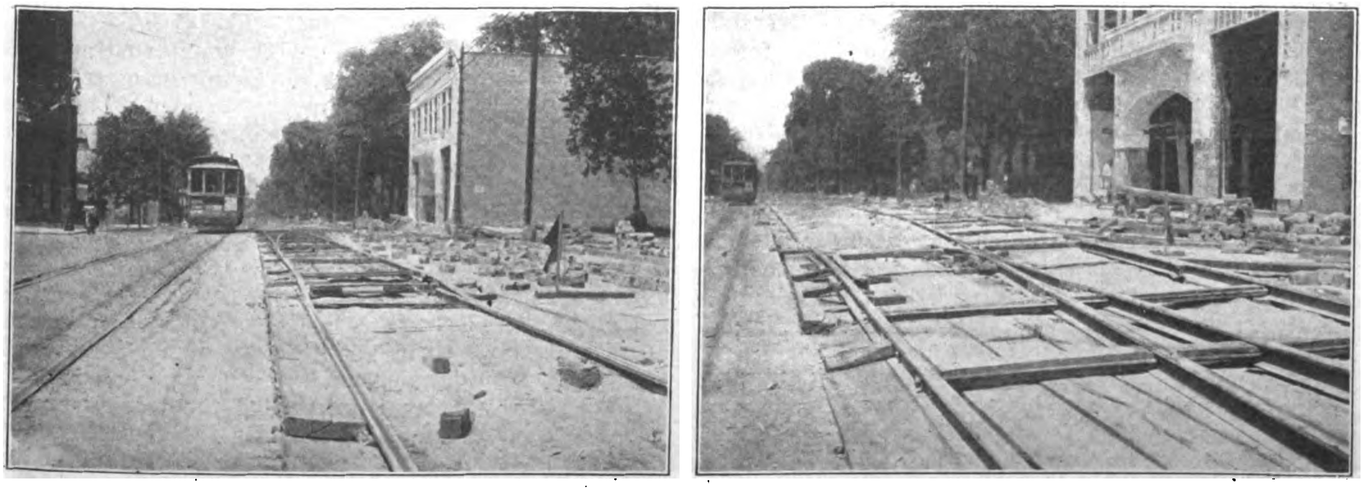
As might be expected, the first form of defect developing in this track was cupping at the joints. During the life period of the track these joints were resurfaced at three different times and ground, and at one of these times the ordinary angle-bars were exchanged for continuous bars. Finally the joints became so loose that reinforcing and grinding was considered impracticable. Moreover, it was not deemed advisable to renew the joints again, owing to the badly worn condition of the ball of the rail. At this time it was decided that it would be an economy to save the foundation, which appeared to be in excellent condition between the joints, by renewing the rail at once, rather than attempting to rehabilitate the joints, and thus obtain the additional wear life out of the old rail.

RECONSTRUCTION MATERIAL

As mentioned before, the 9-in. girder-grooved rail was replaced by a 7-in. 91-lb. T-rail, thus providing a stiffer section laterally as well as one with heavier head and consequently a longer life. In order to provide for the difference in rail heights, 2-in. white oak planks were ripped from the standard cross-ties and laid on the tops of the ties already in the track. These oak planks, as well as the rail, were securely fastened with 8-in. spikes to the ties embedded in the original track construction. The rails were laid in 60-ft. lengths, as in the original construction, but the use of the cast-welded joint instead of the mechanical joint made it necessary to break away the concrete around the old joint ties in order to respace them. Of course in many instances this concrete was badly shattered by extremely heavy impact blows at the very bad joints in the old track, thus requiring the concrete to be renewed or replaced to make a first-class finished job.

The slight variations in the plank shims necessary were first provided for by making these planks vary in thickness from 2 in. to 3¼ in. in ¼-in. variations. These were delivered on the work in sorted lots, and at the time the new rail was placed were merely laid indiscriminately on the old ties. Afterwards a gang of shimmers followed and replaced or shifted these planks to make the new rail surface uniform. Variations of less than ¼ in. were provided for by sheet-metal shims when additional height was needed, or by adzing the planks when it was desired to lower the rail surface. All planks were drilled before they were put in place, so that the spikes would not split them. The sheet-metal shim plates were of the slotted type so that they could be used with other rail-base widths. This 7-in. rail, like the 9-in., was connected at 10-ft. intervals with 3/8-in. x 1¾-in. x 5-ft. 3-in. flat tie-rods. Cast-welded joints calling for 227 lb. of cast metal extending 17 in. along the rails are standard in Detroit and were used on this rail. These welds were made just prior to laying the paving surface, but after the joint ties had been respaced and the shattered concrete at these points replaced.

Standard track paving employed includes a single course of granite nose blocks, 11 in. x 6 in. x 5 in. in size, laid at right angles to the rail, and the space between them surfaced with standard vitrified paving block 4 in. x 4 in. x 9 in. in size. The devil strip between the two tracks was also surfaced with ordinary



D. U. R. TRACK REHABILITATION—ANCHOR POINTS IN PORTABLE SWITCH AND PORTABLE FROG CROSSOVERS vitrified paving block, and the pavement between the outside rails and the street paving, which was asphaltum on Woodward Avenue, included stretcher courses of paving brick sufficient in number to fill the interval opened to rehabilitate the track.

Organization and Procedure

Since it was necessary to continue operating the cars over this street during the period of rehabilitation, a condition customary now in most American cities, it was necessary to have the work well organized and provide ample facilities to accomplish it in the minimum length of time. In Detroit the work is classified into two kinds, that which can be done without interrupting traffic and that which cannot. The latter, of course, may be accomplished during the interval at night when the cars are off the line, and the former includes day-work wholly. In either case, however, the work is more or less retarded, owing to cramped conditions and traffic interference.

D. U. R. TRACK REHABILITATION—METHOD OF LAYING THE BLOCKS AND TEMPLET USED IN LEVELING THE STRIP ADJOINING CITY PAVING

The first gang to arrive on the job is the one which accompanies the work train delivering the temporary track material. This gang installs the portable switches at each end of the passing tracks with a derrick car and lays the track between them. Sometimes as much as a mile of temporary track is laid in one section, and after the night gang has placed it in position the day gang bolts it together and surfaces it. This track is laid on a sand cushion when the pavement is asphaltum, and braces between the outer rail and curb prevent it from shifting toward the curb. On an ordinary brick pavement one plank laid under the outside rail is all that is necessary to surface it. After this temporary track is in position and traffic has been turned over it, active construction work is begun by the paving-excavating gang. This gang loosens and removes all paving blocks, cuts all bolts and prepares the old track as nearly as it can for the rail replacement. This gang usually consists of about thirty men, a foreman and an assistant.

The night gang, consisting of approximately twenty men, completes the work opened by the excavators during the day, loads up the excavated material, or at least load that portion of it which must be removed from the streets, and exchanges the old rail for the new. This gang is usually accompanied by a derrick car and a flat car, and sometimes also by a double-truck motor and two flats. Besides cleaning and replacing the rail this gang also delivers the new material on the job for the following day's work.

The following day the paving gang continues its work, but is followed by a surfacing gang composed of about twenty-five men and two foremen. This gang engages in transferring the shims to their proper positions to give accurate line and surface in accordance with the grade and line stakes set at 50-ft. intervals. After the track has been accurately lined and surfaced by this gang it is ready for the cast welder, which is brought on the job at intervals, preferably when there is a sufficient number of joints to make its coming economical. The cast-welder outfit is usually accompanied by a foreman and thirty-two men, who work either day or night, depending on the requirements.

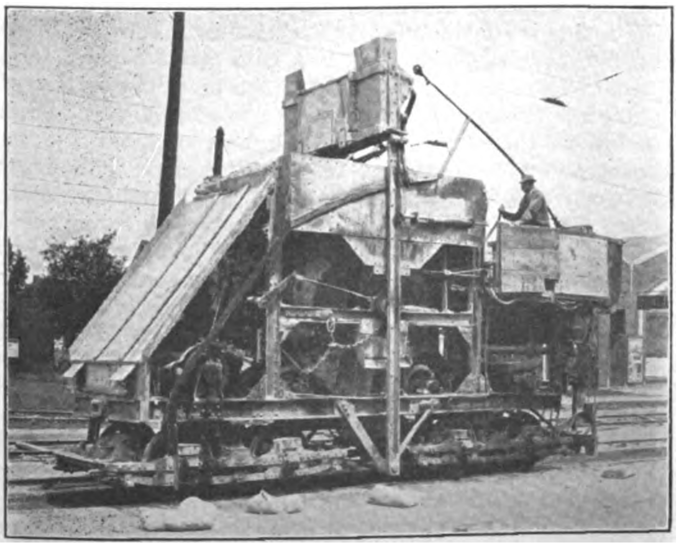
When the welding is completed the track is ready for the concreting, which includes the replacement of that removed at joint ties and that between the ties to bring it up to the paving foundation surface. The concrete mixer, which is of the batch type with three spouts, requires ten men in its operation and has a capacity of approximately 400 yd. per day, or even more when working conditions are exactly right. Views of this mixer are shown in the accompanying illustrations, with the skip in the lowered and elevated positions. It is a self-contained unit, electrically driven and self-propelled. Concrete may be deposited direct to the track or from the spout to wheelbarrows, and wheeled to any point desired.

After the concreting has been completed and allowed to set from seven to ten days, during which time the pavement excavating gang is turned back to complete the paving, the track is turned over for regular traffic. The finished pavement is grouted with a 1 to 3 mixture of sand and cement. Oftentimes it is found necessary to make up for paving-block-thickness variation at the tie-rods by the use of chipped brick. The company has a rule that this chipped-brick course shall be laid two or three courses back of the tie-rod. After the pavers have completed their work, that is to say, that portion including the course between the outer rails and city paving, the city paving gang follows and finishes the joint between its paving and the railway's, and bills the railway company for the work.

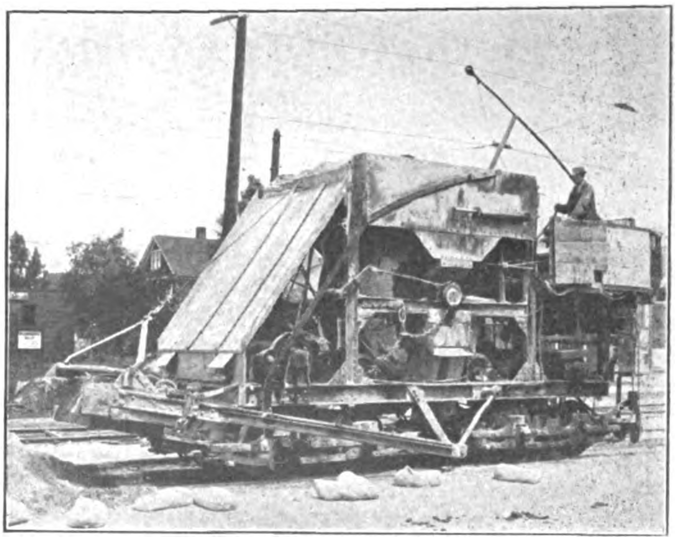
In rehabilitation work of this character the most delicate portion of it must be done by the shimming gang. As already explained, this gang works from grade stakes at 50-ft. intervals or closer, if necessary, and after the men have adjusted the wooden shims the metal shims in various thicknesses are put in place. This gang is trained just for this work and does little or nothing else, and all of its operations are conducted during the daytime. The care exercised in its portion of the job is an index of the success of the whole; consequently the road department believes that too much care cannot be taken by the foremen in charge of this work.

FACILITIES FOR REHABILITATION

Among the facilities used in track rehabilitation which make it possible to do this work and continue operation economically, the portable switch is playing a very important part. John Kerwin, superintendent of track Detroit United Railway, has been a pioneer in the use of portable turnouts and crossovers, especially where the standard A. S. C. E. rail and standard frogs are used. The Kerwin "crossover," or turnout, as it is called, includes a 60-lb. A. S. C. E. rail in 33-ft. lengths, with four-bolt continuous connection plates. The portable track to which it connects is made up in 33-ft. sections, fastened together with four tie-rods to each rail. The two outside tie-rods are 2 ft. 3 in. from the joint, and the inner rods are 8 ft. 6 in. apart. These rods have jamb nuts on each side of the rail, and they are drawn up tight against 3-in. x 6-in. oak spacers, which fit in between the rail webs. In the construction work on Woodward Avenue these rails were laid on oak plank stringers on the asphalt, which in turn rested on from 1 in. to 3 in. of sand cushion, so that the traffic would not scour the asphalt surface.



D. U. R. TRACK REHABILITATION—SELF-CONTAINED CONCRETE MIXER WITH SKIP IN ELEVATED POSITION



D. U. R. TRACK REHABILITATION—SELF-CONTAINED CONCRETE MIXER WITH SKIP LOWERED

Standard Nos. 8 and 9 A. S. C. E. built-up double-spring frogs with 6-ft. anchor points, or beveled switch-points, are used in the portable track turnout. Sections of this track, the switchpoint and frog are shown in the accompanying illustrations. As already mentioned, it is necessary to brace this portable track against the curb in order to prevent its creeping in that direction under traffic. In case the track is laid on a brick pavement a hole is excavated in the pavement at the center of the track, and braces are installed on each side between it and the webs of the rails. After the temporary track has once been delivered to a long section of track undergoing construction, it is shifted as the work progresses in sections just as long as it is possible for the utility motor car to move at one time.

As a rule the day and night work is laid out in sections from 600 to 800 ft. in length. This requires approximately two days before it is possible to change the rail, the first night being consumed in cleaning up the excavating and the second night in unloading material and changing the rails. In order to facilitate the latter, combination joints between the new and old rail are provided and transferred as the work progresses. A view of one of these temporary joints is shown in one of the illustrations.

Other parts of this standard track construction include standard manholes in each depression for surface draining. These are connected to the sewer system and are covered with an ordinary cast-iron perforated cover. Cross bonds are installed at 500-ft. intervals, connecting both rails and both tracks. These bonds are four-strand No. 00 old trolley wire, securely tied and soldered to two sections of a 36-in. strand-wire bond with channel-pin terminals. Holes for these cross bonds and also for the tie-rods are drilled on a piece-work basis by a crew consisting of two men and a boy. This crew is supplied with two electric drills and receives $3\frac{1}{2}$ cents per hole.

Corrosion of Metals in Natural Soils

The Authors Show that Electrolytic Corrosion Can and Does Occur Without Stray Railway Currents and that Two Sets of Conditions May Cause It—Experimental Data Are Given to Prove the Contentions

BY E. H. SCOFIELD, ENGINEER POWER AND EQUIPMENT, AND L. A. STENGER, CHEMIST
MINNEAPOLIS RAILWAY COMPANY

Steel, wrought iron, cast iron and lead corrode in the soils found in the streets of cities where service piping systems are installed. Such corrosion occurs both in the form of uniform rusting or oxidation at the surface, and as the more destructive pitting. The former is generally recognized as a simple chemical action and is considered to be limited in its action and not likely finally to destroy the metallic structure affected. The latter is usually attributed to so-called electrolysis, and when found in localities where electric railways operate the damage is charged to the action of electrical current originating from the return circuits of such railways.

The discovery of numerous cases of destructive corrosion, fair samples of which are shown in Figs. 1, 2 and 7, in localities where there was found to be no possibility of the presence of electric current in the earth originating from commercial electric circuits, led to a search for the causes of such corrosion. Fig. 1 shows a sample of a 4-in. cast-iron water pipe, removed from the natural earth in a city where no electric railways or leakage currents exist. The shell of the pipe was entirely corroded away at several points, while there were deep pits at others. Fig. 2 shows sample of a 1-in. mild-steel pipe, removed from the earth at a location where no leakage currents existed, but where the corrosive condition of the clay soil was very active. Fig. 7 represents a section of corroded lead pipe taken from a mixed, black soil containing cinders and other impurities. No leakage currents could be detected flowing on or from this pipe.

It is the purpose of this article to report the investigations made to determine these causes of corrosion, their nature and the damage that might be expected to arise from them. The investigations disclosed two different classes of phenomena. The first affects metals having more or less impurities in their structure, as iron, either cast or wrought, or as steel. The second affects any metal regardless of internal impurities, such as lead which, from its peculiar chemical properties, is ordinarily regarded as non-corrodible in soils. These two classes of phenomena will be discussed in turn.

CORROSION DUE TO IMPURITIES IN METALS

Reports are available from various sources showing the effects of impurities and irregularities in structure of metals on their electrical conditions. Experimental demonstrations may be made, showing that electric currents are generated when such metals are immersed in, or subjected to the action of, electrolytes. This fact has been advanced as an explanation of the damage done to metals exposed to the atmosphere, but very little attention has so far been paid to the corresponding effect on metals exposed to and in contact with soils.

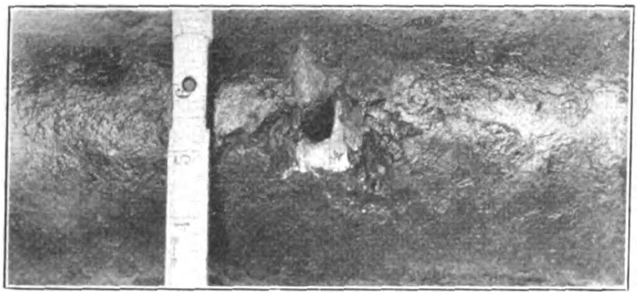
For these experiments two identical terminals were prepared, consisting of platinum plates about 1 in. square. Copper terminals might also have been used. A handle and a connecting wire were riveted in the center of each plate and the connecting wires were, in turn, joined to the terminals of a 15-volt-scale voltmeter. The plates were covered with pads of muslin or filter paper, which serve to prevent metallic contact and to hold a small amount of electrolyte. The electrolyte will be more or less chemically active, according to the kind and amount of components existing in it capable of combining with iron. For a simple, standard electrolyte for the experiments, the pads were wet with very weak sulphuric acid. Tests made with certain black, peaty soils and clays as the electrolyte have shown electric potentials of as great magnitude as have been obtained by the use of this acid. When the pads containing the same electrolyte were placed in contact, no voltage was generated, but in surveys made by placing the pads of the terminals at different points over the surface of various irons emfs were developed as follows: sheet iron, 0 to 0.5 volt; steel pipe, 0 to 0.5 volt; cast iron pipe, 0 to 0.3 volt; pitted cast iron, 0 to 0.7 volt; clean cast iron, 0 to 0.15 volt. In every case the emf's were in such a direction as to cause the current to leave the points where the iron was clean, and to return to the impurity after flowing in the outside circuit. Thus it is evident that the clean iron is electro-positive and the impurity is electro-negative.

The cause of the potential difference is found in the tendency of the pure iron ions to combine with any acid ions in the electrolyte, and to leave the metallic state. This tendency is called the solution tension of the metal and is, in the case of iron, of a comparatively high value.

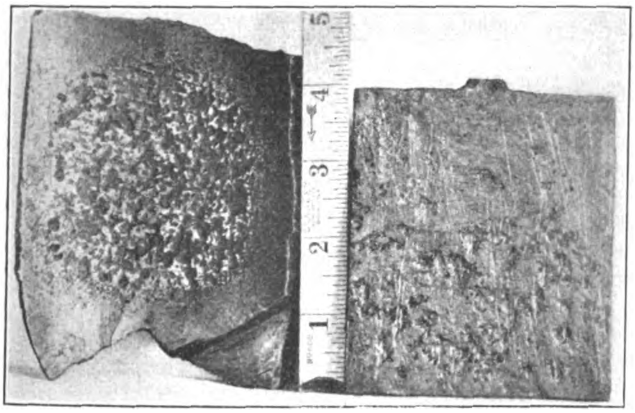
The question will at once arise as to the continuity of this battery action. Obviously the current flow will not decrease unless the conductivity of the circuit is decreased. In case of iron buried in chemically active soil, conditions will tend to increase conductivity in all features except one, that involving polarization, or the plating of a non-conducting film of hydrogen on the negative pole. Theory points out that the free oxygen in the soil and water therein will combine with the hydrogen and allow the action to continue. All experiments and the cases of corrosion examined seem to show that the action is continuous. One cell in particular was made up by using two pieces of cast iron about 4 in. square, broken from the same length of 6-in. pipe. The outside of one piece, already corroded, was placed facing the clean inside of the other, the two supported about 1½ in. apart by a section of 3-in. fiber piping. The space between was filled with moist, peaty soil and the joints were sealed with paraffin wax to prevent a too rapid escape of moisture. The two iron plates were connected through a milliammeter, and a voltmeter was connected across the terminals. The open-circuit voltage generated was 0.7, and the component of current generated, indicated on the outside instrument, was 0.004 amp. In a couple of days the current dropped to a constant value of 0.001 amp. After four months on short-circuit, some pure distilled water was added and the increased conductivity caused the current to increase to 0.004 amp. The cell was then left on short-circuit and, upon opening it after about twenty months, the soil was found to be dry and the iron plate which had the clean inside surface exposed was covered with a thick mixture of iron rust and soil. Under this pits about 1/16 in. deep were found filled with the usual carbon-like deposit.

A number of cells, made up of carbon rods and pieces of cast iron as electrodes, placed in various samples of soil gave voltages of from 0.1 to 0.9, and external current flow of from 1 to 10 milliamp, depending upon the kind of soils and their moisture content.

Fig. 3 shows at the left a sample section of pipe used to make up the cell with iron plates referred to above. The surface exposed to the action of the soil is very sharply defined in contrast to the original surface not so exposed. The pits in it are 1/16 in. deep. The sample shown on the right is a cast-iron plate used with a carbon rod to make up battery couple with soil as the electrolyte.



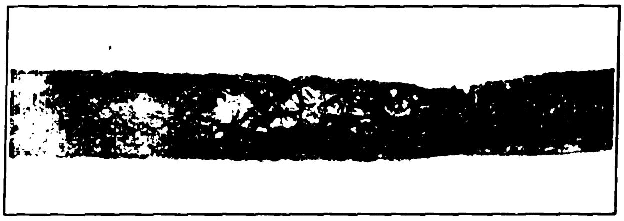
CORROSION OF METALS—FIG. 1—LARGE CAST-IRON WATER PIPE, SHOWING NATURAL CORROSION



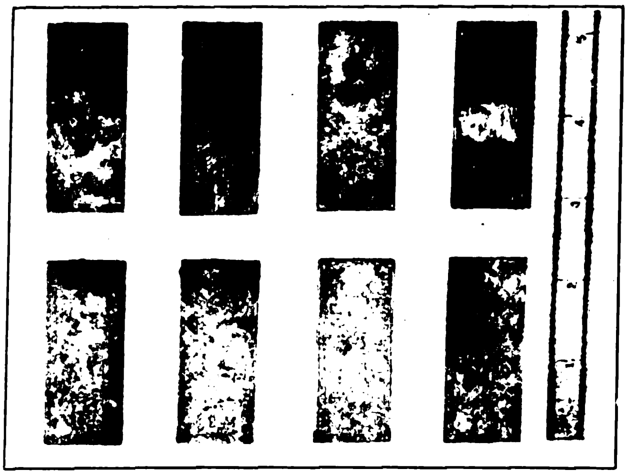
CORROSION OF METALS—FIG. 3—PIPE AND CAST-IRON PLATE CORRODED BY CONTACT WITH SOIL

Considering the practical case of iron buried in soil, there are fulfilled all conditions necessary for the destructive action of these naturally-generated currents. The water in the soil, carrying with it the soluble chemicals which it encounters by seepage through the ground, is the electrolyte. This furnishes the acid ions ready to combine with the metal. These ions act not only once but recurrently, whence a soil of small acid content having an alkaline or neutral reaction, due to natural chemical combinations with other elements may be active in producing corrosion. The electrical currents generated will flow in the shortest circuit they can find through the soil from the corroding, clean metal to the nearest impurity or negative pole on the pipe. There would be ample oxygen available to act as depolarizer. It would be difficult to produce in the laboratory experimental conditions as favorable to corrosive action as actually exist in the case of iron structures buried in the soil.

Tests were conducted on 120 samples of representative soils for the purpose of determining their comparative chemical activity in promoting iron corrosion. The moisture content of each soil as sampled from the natural location was determined. A sample of about 400 grams of each was taken and placed in a glass beaker. This beaker was set in a larger covered beaker containing water to prevent moisture loss from the soil. Mild steel plates, 1 in. x 2¼ in., were cut from the same piece of black No. 16 sheet and were numbered, weighed and placed in the soils, one only in each beaker. After remaining sixty-six days in the soils the plates were removed, cleaned and weighed. Fig. 4 shows samples of steel sheet used in making the tests on the relative corrosion of various samples of soil. It shows localized corrosion and pitting .014 in. deep. The loss in weight was considered a fair measure of the corrosive power of the soil. It was found that all of the plates lost in weight. In clean sand the loss was least, of the order of 0.04 gram. Light sandy clays, loam and drier dark soils produced losses of from 0.15 to 0.20 gram. The plates immersed in heavy clays, carrying 10 per cent to 15 per cent of water, lost by corrosion from 0.20 to 0.40 gram and those in wet, black, peaty soil lost 0.6 gram.



CORROSION OF METALS—FIG. 2—MILD-STEEL PIPE CORRODED IN CLAY SOIL

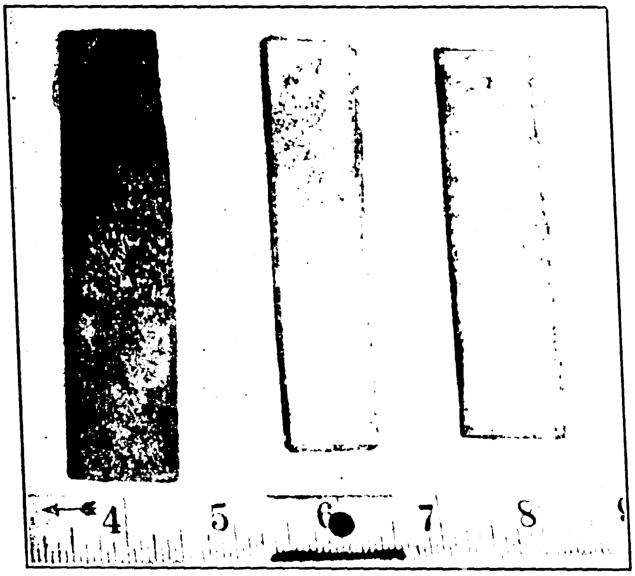


CORROSION OF METALS—FIG. 4—CORROSION OF MILD STEEL SHEETS BY VARIOUS SOILS

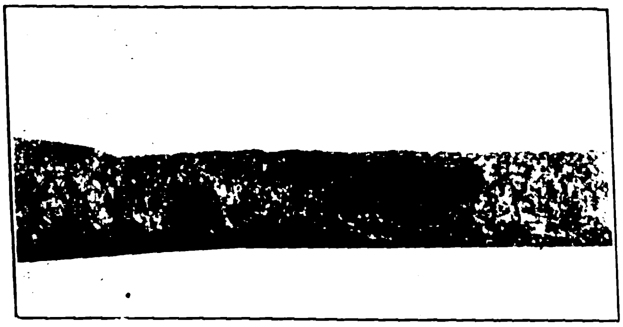
Taking, from the results of these experiments, the average value of 0.25 gram iron loss per sixty-six days, or 1.39 grams per year, as found in common yellow and blue clays, we can determine the approximate life of iron pipe in such soil. Assume that a pit would be made having a conical shape, an area on the pipe surface of 1 sq. in., and a depth of the pipe wall thickness of ¼ in. The iron from this pit would weigh 10.6 grams and, dividing this by the rate per year, we have 7.6 years as the probable life in these clays of a black iron pipe with ¼-in. wall. Cases have come under our observation where pipes which were poorly galvanized lasted but three years in clay soils before leaking, while wrought-iron and steel pipes had from four to six years' life in locations where there would have been no causes of corrosion other than chemical activity of the soil.

A sample of 3-in. cast-iron gas pipe was removed from a location where no stray current was indicated. This pipe was said to have been in service about twenty-seven years, and lay in a mixture of loam, black peat and clays. The present weight of this pipe is 27.5 lb. The probable weight of the piece of pipe as it was installed, calculated from its dimensions and assuming the specific gravity of the cast iron as 7.1, was 34.3 lb., whence the iron lost by corrosion was 6.8 lb., or the equivalent of 8.22 grams per square inch. Assuming a period of five years for disintegration of the tar coating, allowing corrosive agencies full action, this leaves twenty-two years as the time for corrosion to act.

Samples of soils were also taken from around this pipe. Cast-iron plates were placed in these soils in their natural state, in glass beakers, and the loss of iron from the specimens was determined by weighing after a period of sixty-six days. The iron plates were 2¼ in. x 1.05 in. x ⅛ in. in size, about 5.55 sq. in. in area, and were cast to this size. They were quite hard due to chill, and were mechanically cleaned only enough to remove sand and such impurities. The loss due to corrosion in the black peat was 0.8 gram. In the blue clay it was 0.6 gram, in the loam 0.5 gram, and from an average mixture taken at the pipe location 0.4 gram.



CORROSION OF METALS—FIG. 5—CORROSION DUE TO TWO DIFFERENT SOILS IN CONTACT

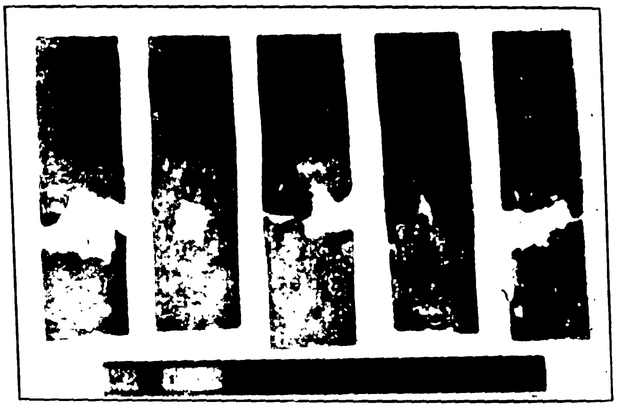


CORROSION OF METALS—FIG. 7—LEAD PIPE CORRODED BY CONTACT WITH MIXED BLACK SOIL

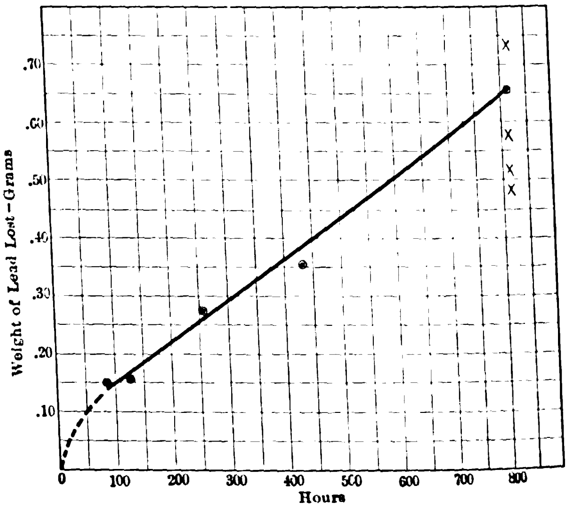
On calculation, assuming that corrosion proceeds at the same rate, these figures show, for 0.8 gram, a loss of 17.6 grams per square inch per twenty-two years, or, for 0.4 gram, 8.8 grams per square inch per twenty-two years. Whence, as an actual loss on the pipe of 8.2 grams per square inch per twenty-two years was found, it is readily seen that the damage done to this pipe may be fully accounted for on the basis of natural soil corrosion.

CORROSION DUE TO THE PRESENCE OF TWO OR MORE DIFFERENT ELECTROLYTES

The condition that causes damage from corrosion of the second class arises from a combination of a metal and two soils of different composition. The theory of this type of corrosion is based upon the easily-demonstrated experiment of physical chemistry in which an electric current can be generated by contact of two solutions of different chemicals combining power or valence. Given metal in contact with two soils, one of which contains any soluble substance subject to change, as carbon in its various combinations of gas or organic matter, nitrogenous bodies or sulphur, we may expect an electric current to flow. The current will enter and leave the metal, as a convenient conductor, in the proximity of the bi-electrolytic soil, and produce corrosion where it leaves the metal.



CORROSION OF METALS—FIG. 6—LEAD FOIL STRIPS CORRODED BY BI-ELECTROLYTIC SOILS



CORROSION OF METALS—FIG. 8—RATE OF CORROSION IN BI-ELECTROLYTIC SOIL

To demonstrate the theory and fit it to practical cases, electrodes of various metals were used. Lead proved to be the most satisfactory, as iron set up its own electromotive forces which masked the effect, and bright platinum polarized too rapidly. A cell was made up of two types of soil in contact. A lead electrode was placed in each soil and the two electrodes were connected through a voltmeter. Voltages were generated. The lead electrodes in either of the soils alone would show no traces of electric potential, if the soil were reasonably homogeneous.

A number of cells of various combinations of soils, cinders and sand were experimented with. Some gave as high as 0.1 to 0.4 volt, but not all soils would produce corrosion under these conditions. Clean sand and clay did not produce the effect, as both of these have presumably been previously reduced to their most stable chemical state.

To demonstrate corrosion under these conditions cells were made up in glass beakers with horizontal layers of two different soils as electrolyte and a single strip of lead as the corrodible metal, with the ends exposed, one to each of the soils. One cell with 1/16-in. commercial sheet lead, and with black soil and cinders as the two electrolytes, showed a corrosion loss of 0.14 gram of lead in seventy hours. Corrosion was all on the soil end as is shown by the illustrations in Fig. 5 which represents samples of lead plates in electrolyte made up of two different soils in contact. The lower half of each sample is corroded. The other end, although it appeared rough on the plate, was slightly discolored by oxidation and carbonization but it was not corroded. Four similar cells were set up, with black peaty soil and dirty clay as electrolytes, and with 1.2-in. x 4-in. strips of pure lead foil, 0.006 in. thick, as the metallic conductor. The lead strip from each cell in turn was removed at intervals, weighed and returned to the cell. This gave data to test the rate and continuity of corrosion. The results as obtained are plotted against time in hours in Fig. 8. In this figure the corrosion at the end of each interval of time for each cell is indicated by circles, and the total corrosion for each cell at the end of 800 hours is indicated by crosses. The curve shows a rapid rate of corrosion for the first 100 hours, after which the rate became constant for the remainder of the test. The total corrosion loss for each cell at the end of the full time was approximately the same as found in the others. The end of the strip in the clay was corroded, while the other end in the peat was in the original condition except for slight surface oxidation. In Fig. 6 samples of lead foil used to demonstrate the destructive corrosion of lead when exposed to action of two different soils in contact are shown. These samples were exposed for a total of 817 hours. The curve given in Fig. 8 shows the time rate of corrosion of these samples.

This latter test is of particular interest in view of the fact that the conditions are such as are found when lead pipe is laid in a trench and the trench is refilled with a mixture of earths of different character, as is usually found in a trench from 3 ft. to 6 ft. in depth. Fig. 7 shows corrosion of such a lead pipe in soil.

The corrosion results of these tests and the appearance of the specimens are such as to fully explain all observed phenomena usually attributed to electrolysis by ground leakage currents. The cast-iron samples, where corroded, were covered with a hard scale of red rust and soil. The pits in the cast iron were filled with carbon and black-iron oxide. The pitting was localized, the space between pits being but slightly corroded. The lead samples show the presence of both the gray and brown oxides. The line between corrosion and non-corrosion, where the metal was exposed to two kinds of soils, is sharply defined. Potential differences up to 1 volt were generated by placing different metals in contact with certain soils, or by placing two pieces of similar metal in contact with different soils.

An ordinance went into effect in Topeka, Kan., on Nov. 1 which provided that automobilists must not pass within 8 ft. on either side of a street car not in motion. The original ordinance provided that no automobile should pass within 8 ft. of the running board of a street car, and the change was made because some street cars have running boards on only one side.

Taxation Values in Illinois

James J. Brady, auditor of public accounts of the State of Illinois, has compiled a tabular statement of the amount of taxes charged for collection against the equalized assessed valuation of steam railroad and interurban electric railway property for 1913. The following summary is taken from Mr. Brady's analysis:

TABLE SHOWING 1913 TAX FIGURES FOR ILLINOIS INTERURBAN ELECTRIC RAILWAYS

Electric Roads	Equalized Assessed Valuation of Property in Illinois	Total Taxes Charged on Tax Books	Rate Per Cent of Tax on each $1 Assessed Valuation	Rate Per Cent of Taxes on Each $1 Gross Earnings
Alton, Jacksonville & Peoria...	$79,261	$2,509	3.17	7.93
Aurora, Elgin & Chicago......	695,511	29,598	4.26	1.62
Bloomington, Pontiac & Joliet.	52,607	1,488	2.83	6.27
Joliet & Southern Traction....	219,238	7,219	3.29	4.41
Total	$271,845	$8,707	3.20	....
Central Illinois Trac. Company	$38,349	$1,493	3.89	2.09
Chicago, Aurora & DeKalb....	91,738	2,816	3.07	3.70
Chicago & Des Plaines Valley..	222,870	11,696	5.25	2.21
Chicago, Harv'd & Geneva Lake	21,956	675	3.12	4.38
Chicago & Interurban Traction	225,791	11,164	3.14	4.31

Examination for Examiner of Accounts

The United States Civil Service Commission has announced an open competitive examination for examiner of accounts for Grade 2 position only, the salaries being from $1,860 to $2,100 per annum. Applicants will not be assembled for examination but will be rated upon the evidence as to education and experience. Applications must be in by Dec. 1. From the registers of eligibles resulting from this examination, which will be made up for electric railway and other single accounting branches, certification will be made to fill vacancies as they occur for accountants in the division of valuation and for examiners of accounts for the division of carriers' accounts, Interstate Commerce Commission.

National Civic Federation Draft Bill

Abstract of Main Features of Bill Drafted by Executive Council of the Department on Regulation of Interstate and Municipal Utilities of the National Civic Federation, Together with Representative Suggestions for Amendment of the Bill—Also Memorandum of Transmission by Seth Low and William R. Willcox and the Dissenting Report by E. M. Bassett, John H. Gray and Milo R. Maltbie

The National Civic Federation has just made public its draft bill for the regulation of public utilities, together with accompanying sections which trace the history of the bill and discuss some of the points of disagreement. An introductory statement and memorandum by Seth Low and William R. Willcox, the report of the department on regulation of interstate and municipal utilities, signed by Emerson McMillin, chairman of the executive council, and the dissenting report by E. M. Bassett, John H. Gray and Milo R. Maltbie, all precede the text of the bill. Appendix A, prepared by William D. Kerr, is a résumé of the suggested amendments to the bill, with arguments pro and con, while in Appendix B there is presented a schedule of existing regulatory commissions. Appendix C is a reprint of the 1907 conclusions of the commission on public ownership and operation of the federation. The drafting of the proposed bill is regarded by the federation as a logical outcome of this former report, which concluded that in this country, under the conditions of municipal politics, private ownership and operation would be preferable to public ownership and operation, provided there were adequate regulation to protect the public from extortionate rates and deficient service.

HISTORY OF BILL

According to the résumé by Messrs. Low and Willcox, who were appointed as a special committee of the executive council of the federation to consider all questions relating to the draft bill, the active work resulting in the present bill was begun in 1911, when, after a conference of those interested in utility regulation, it was determined to create a department to prepare such a bill. The department thus formed appointed an executive committee composed of the following members: Emerson McMillin, American Light & Traction Company, New York, chairman; Franklin T. Brown, Redmond & Company, New York; John H. Gray, head of the department of economics and political science, University of Minnesota; Edward M. Bassett, attorney and former member Public Service Commission for the First District of New York; Halford Erickson, member Railroad Commission of Wisconsin; William D. Kerr, attorney, Chicago; Blewett Lee, general solicitor Illinois Central Railroad; Milo R. Maltbie, member Public Service Commission for the First District of New York; Arthur Williams, chairman Association of Edison Electric Companies, and Franklin K. Lane, former member Interstate Commerce Commission (resigned on account of official duties before drafting of bill).

Inquiry revealed the fact that all states except Delaware, Wyoming and Utah had regulatory commissions of some sort. After making a complete compilation of all statutes relating to such bodies and investigating thoroughly all court decisions and general literature on the subject, tentative sections for a sample public utility bill were drawn up and sent to all commissioners and other selected and interested parties for criticism. Upon the receipt of many suggestions and criticisms and the amendment of the bill in many cases accordingly, the executive counsel of the department prepared the present draft of eleven articles and more than 300 sections. Of these sections as drafted only sixty have been criticised by anyone, from which Messrs. Low and Willcox conclude that the draft bill as a whole embodies a form of legislation which meets with wide approval, except as to such sections as deal with matters upon which differences of opinion are inevitable.

As the preparation of the draft bill proceeded it became apparent that it would be impossible to secure a unanimous approval by the department of this bill or of any other dealing with this subject. The draft bill, therefore, and the dissenting report by Messrs. Bassett, Gray and Maltbie were laid before the executive council of the National Civic Federation at a special meeting in January, 1914, without having been submitted to the department as a whole. In view of this circumstance, Messrs. Low and Willcox recommended that the names of those comprising the department on the regulation of public utilities be omitted from the document, as it was evidently unfair to hold the members in any way responsible for a measure upon which they had not had an adequate opportunity to pass. The present bill, therefore, is published upon the authority of the executive committee of the department on the regulation of public utilities, subject to the reservations embodied in the minority report.

According to Messrs. Low and Willcox, the differences in regard to the bill reflect the differences in the points of view. They say that the radicals are inclined to press regulation to the limit, even if it made it impossible to secure private capital for the construction and the conduct of public utilities. In the minds of many of them, public ownership and operation loomed up as not objectionable alternatives. Those who have to do with the procuring of private capital for public utilities, however, believe that too much regulation will easily make private capital unavailable and lean toward limiting regulation as much as possible. Yet in this conservative element, there are again great differences of opinion, for some believe in public regulation and wish to make it practicable and successful, while others accept it reluctantly and are fearful of any limitation which may interfere with established practices. In the opinion of the special committee, the National Civic Federation cannot pretend to pass judgment on the issues thus raised, and the wise course to be followed lies between the two extremes.

MEMORANDUM BY MESSRS. LOW AND WILLCOX

In the belief that the function of the federation is to make the bill as useful as possible by throwing various lights on it, Messrs. Low and Willcox subjoined to the foregoing résumé a memorandum on some of the large questions involved, for which they did not ask the federation to become responsible. In their opinion, the problem to be worked out in connection with the public regulation of such utilities, is how to give power enough to the regulating commission to enable it to prevent the abuses to which uncontrolled private management has been shown to be subject, without making exactions so severe as to render it impossible to secure the private capital necessary to maintain existing facilities in a high state of efficiency and to develop new enterprises when such are necessary. Any public service commission must have large discretionary powers and it is probably better to make this discretion large, despite the possibilities of abuse, than by making the law too rigid to make it impossible for the commission to deal equitably with exceptional conditions.

The draft bill leaves to the representatives of the public the determination of values against which stock or bonds are to be issued, upon the theory that if regulation means anything it means this, so that both investors and the public served may be protected against fraudulent practices and exaggerated values. Under the draft bill appeals may lie to the courts from the action of the commission on questions of law but not on findings of fact, such as value. Some of those who are engaged in establishing new public utilities hold the view that upon questions of value, if upon no other question of fact, there should be an appeal to the courts.

If the public assumes responsibility for the values against which stocks and bonds may be issued it is held by some that the public becomes morally responsible for the existence of such values. There is at least the possibility that in time the public will be asked to guarantee the values which it stands sponsor for. Should the time come when the public is willing to do this, it can undoubtedly secure private funds for such enterprises at much lower rates of interest than can be had at the present time. On the other hand, because the fixing of values by the public perhaps tends in this direction, there are those who maintain that public regulation should not attempt to determine values, but should call for the most complete publicity. Under such a system private investors would be given the fullest possible information and would then be expected to look out for themselves. There would be nothing in such a case to protect the public against unreasonable financial burdens as these affect good service, except the arbitrary discretion of the public service commission in fixing rates.

It has been suggested that joint use of facilities should not be permitted between competing companies. The draft bill, however, recognizes the propriety of joint use under certain conditions even in such cases, and it confers upon the commission ample authority to prevent competition where this is not in the public interest. Yet wherever the joint use of any facility is permitted, the management should always be left in full control of the owner.

The draft bill deals with the question of depreciation upon the assumption that this term is broad enough to include obsolescence and replacement. In telegraphing, "depreciation" would usually provide adequately for replacement, but in telephoning the principal cost is not in lines and poles but in service stations. For the best service, apparatus that is comparatively new must often be discarded in order to give place to the latest improvement. The same thing is true in power houses of electric railways and probably in a greater or lesser degree in connection with every public utility which depends upon so new a science as electricity. It is very difficult to lay down a general rule for depreciation applying to all cases. Probably there is no way to deal with this question in a law except to give wide discretion to the commission. Sometimes the creation of a depreciation fund board to adjust the matter from year to year in the light of actual circumstances may offer a wise solution of this very difficult problem.

As regards state versus local franchises, it is hardly conceivable that any locality will willingly abandon its right to say whether or not a franchise shall be granted for the use of any of its streets or public places. To this extent the co-operation of the locality with the state commission is probably essential. But many public utilities serve more than one locality, and for these there must be state regulation. A state commission will necessarily have a wider experience than any purely local commission can acquire except in the very largest cities, and ordinarily it can command a higher grade of expert service for its guidance. To submit questions of rates to a local commission is practically to permit the users of the service to say what should be paid for it.

The indeterminate franchise is the best form of franchise, in the interest of the public as well as of the public service corporation, which has yet been developed. It would appear to be fair to permit a locality which has assented to a fixed term franchise to pass upon the conditions of exchange when such a franchise is given up for an indeterminate one. Any attempt to bring about such an exchange by general law without the consent of the locality would be likely to evoke popular resentment because of its unfairness. By the draft bill, a new locality to be served must give its consent, which in its nature will be indeterminate. In doing so, the locality can attach conditions not inconsistent with the provisions of the bill itself.

A local holding company of a local public service corporation would seem to be of no possible advantage to the public. Yet a holding company which controls the operations of many small public service corporations in as many different localities may offer the public many advantages. In the view of some the method of financing proposed by the draft bill would be likely to force the creation of such holding companies in order to provide adequate funds for local service. Whether this be so or not, such a company under broadminded management might give better service to every locality controlled by it than any small-sized locality could command for itself. Whether or not a local company should pass under the control of a holding company and what arrangements should be made in such a case for the protection of minority stockholders, would seem to be legitimate subjects for the discretion of a public service commission.

Some standard of action must be laid down by law for the capitalization of consolidated companies. The draft bill leaves large discretion to the judgment of the commission. The dissenting report simply proposes a different standard.

The issue between public ownership and operation and private ownership and operation under public regulation is not wholly and perhaps not primarily a question of economics. The application of the state civil service law to the men employed by the private electric railway whose system was taken over by the municipality of San Francisco resulted in many members of the local union losing their positions. The effect was so serious that the American Federation of Labor sent a commission to Europe this year to study particularly this aspect of the question. The civil service system and regulation of rates of pay by law are inconsistent with the methods and objects of collective bargaining by organized labor. If anyone imagines that collective bargaining, including the right to strike, may be permanently enjoyed in connection with public service, he should recall what happened in democratic France when the railroad employees went upon a general strike. The men were ordered to the colors and the strike was broken. The attempt to carry out the methods of collective bargaining and the right of striking in connection with the public service is the pathway toward placing every public employment upon a military basis. Such questions as these far outweigh in public importance the financial questions that are involved as between public ownership and operation and private ownership and operation under public regulation.

CONCURRING AND DISSENTING REPORTS

Mr. McMillin, chairman of the executive committee of the department on regulation of interstate municipal utilities, submitted the majority report to the effect that the bill is offered in the belief that, as far as it may be adopted, it will lead to a better understanding between public utilities and the public than has heretofore been possible under less carefully drawn legislation and that the regulation thereunder will be just and fair to the investor, the owner and the user of the service.

The dissenting report by Messrs. Bassett, Gray and Maltbie criticised the bill as giving commissions no jurisdiction over holding companies. The subterranean and indirect method of buying up 51 per cent or more of the stock of a public utility could be resorted to without any check, approval or even investigation, and no protection is provided for minority stockholders. The bill should henceforth prohibit any additional shares passing into the hands of holding companies without investigation and approval by the commission. Purchases of stock in other public utilities should be subject to similar restriction, and companies not public utilities should be prevented from acquiring stock in public utilities beyond a certain small percentage. Moreover, the commission should always have power to impose conditions and enforce regulations to protect minority interests and public rights.

The three dissenters also believed that in no case should the capitalization of a merged or consolidated company exceed the capitalization of the former individual companies. No commission should be practically forced by law, if companies so desire, to make value a basis for recapitalization. All the more progressive states forbid the direct capitalization of surplus simply because it is surplus, and it should not be capitalized indirectly by means of consolidation. The present bill practically invites consolidation of companies that have a surplus with companies that have watered capital.

The sections relating to franchise grants and municipal operation should be either omitted entirely or redrafted along different lines. Particularly objectionable are the sections which undertake virtually to deprive cities of all control over franchise grants affecting their own streets. Any utility now operating might under the proposed law obtain a new franchise without the consent of the municipality, abutting property owners or the state itself. Moreover, municipal authorities would have nothing whatever to say as to the terms of any automatically renewed franchise.

FEATURES OF DRAFT BILL

The bill provides for a commission of five members appointed by the governor for five-year terms. Besides the usual powers of supervision and investigation, the commission is empowered to determine the cost or value of public utilities. Rates fixed by the commission must be observed for a period to be set not exceeding three years.

No provision in the bill is to be construed as obligating the state to pay or guarantee securities or any interest or dividends thereon. Securities are to be issued in an amount reasonably required to enable the utility "to perform its duty to the public." Stock or stock certificates may be issued only for money, or services or property at the true money value thereof as determined by the commission, equal to or in excess of the face value of the securities. Bonds and other evidences of indebtedness may not be issued below 75. The commission may require the utility to provide for the amortization of discount and expenses over a fixed period. No public utility shall declare any yearly dividends until provision has been made for this accrued amortization. The bond issues must bear a reasonable ratio to the stock issues, due consideration being given to the nature of the business, credits, earnings and prospects and the securing of an adequate relative amount of financial interest and risk on the part of the stockholders.

No contracts for consolidations, mergers, leases, or franchises (in excess of amount paid to state for granting, exclusive of taxes) may be capitalized. The capitalization of a merged or consolidated property must not exceed the value of the individual properties as determined by the commission. If the commission determines that capital has been or is being impaired or that securities have been issued for purposes properly chargeable to income, it may require the utility to set aside periodically a portion of earnings or moneys not derived from the sale of securities and prescribe rules governing such a fund.

The commission receives the power to provide joint rates and to enter into an arrangement with a utility for the automatic adjustment of charges. It may investigate all interstate rates affecting acts within the state and apply to the Interstate Commerce Commission for relief. It may enforce emergency rates for thirty days, to be renewed only after an investigation.

Every municipally owned and operated public utility must comply with the commission's orders regarding accounting procedure and reports. Each public utility shall carry a proper and adequate depreciation account under commission rules. The commission may from time to time fix proper and adequate rates of depreciation on the several classes of public utility property. Money set aside for depreciation shall be expended, until required for renewals and replacements, only for purposes chargeable to capital, for the retirement of obligations or for any other authorized purpose. The commission may direct a utility to make provision from income other than from capital sources for an impairment of capital due to depreciation and other causes, which impairment was not provided for through charges against revenue or otherwise at the time of its occurrence or subsequently.

Every utility when required by the commission must file a certification by a public accountant that it is complying with the prescribed accounting system. The commission may require this accountant to be not a shareholder, officer or permanent employee of the utility.

Franchises hereafter granted are to be indeterminate in form. Existing limited franchises may be exchanged for indeterminate ones on filing a consent to future municipal purchase, the new franchise to be subject to alterations, amendments or repeal by the legislature. No municipality can hereafter enter into the original construction of a municipal plant for public utility service in competition to a similar existing plant without obtaining a certificate of public convenience and necessity. When a municipality desires to take over a utility, the commission must set the compensation in one year from the date of the first hearing. In the case of a utility extending outside the municipality, the commission must determine how much shall be purchased. The municipality owning a utility may contract with a privately owned utility for the operation of all or part of the municipal plant.

Complaints for reparation must be filed within two years. The penalty for rebates is three times all sums received or accepted for six years prior to action. In connection with the enforcement of the act rigid penalties are provided, extending from misdemeanors with $5,000 fine for violations of orders or divulging commission information to felonies with five years' imprisonment for acts involving moral turpitude, such as falsification or destruction of records.

RÉSUMÉ OF SUGGESTED AMENDMENTS

Mr. Kerr's résumé of points in favor of and opposed to various features of the bill, as brought out in conferences and correspondence, covers such subjects as the following: Commission supervision over the operation of municipally owned and operated plants, publicity of records, effective period for rates fixed, issuance of securities, capital of consolidated companies, indeterminate franchise, rates, depreciation and municipal purchase. The character of the résumé is shown by the following abstracts of material concerning the last three points:

To the minds of some the bill should make clear that inadequacy is an element in judging rates just as much as justness and reasonableness. In reply, it was asserted that the rule of justness and reasonableness includes adequacy and every other element of rate reasonableness. On the other hand, it was stated that were the rule changed to specify adequacy as one of the elements of reasonableness, the courts would be likely to assume jurisdiction on the determination of what constitutes adequacy in a particular case, which would be undesirable. It was also said that no change should be made in any rates before authority therefor had been obtained from the commission, but the public utility should not be relieved of its duty of fixing rates in the first instance, subject only to supervision and exercise of mandatory powers in case of necessity. In answer to statements that an investigation of interstate rates by the state commission would result in a double investigation, it was asserted that it is a proper function of the state commission to report to the Interstate Commerce Commission matters which it thinks require remedying but which it has not the power to take up.

The sections regarding depreciation roused considerable difference of opinion. It was suggested that each utility should be required to make such reasonable provisions for the replacement and renewal of its property as was necessary to enable it to maintain the adequacy, efficiency and quality of its service, but not to attempt to provide a fund to offset theoretical depreciation. It is pointed out, however, that whether depreciation means so-called theoretical depreciation or merely provision for replacements and renewals, the draft bill does not attempt to say. The fundamental purpose of a depreciation account seems to be to keep a continuing and accurate balance between property values and the amounts at which they are entered in the books of accounts. In the case of a going concern, it would be absurd to apply the depreciation sections of the draft bill so as to accomplish over a period of years by regular deductions from earnings the creation of a fund held intact equalling the original cost of the property. To the drafters of the bill the term "depreciation" is used generically to denote loss of value, whether due to wear and tear, natural causes, improvements in the art, or what not.

It was thought that a municipally owned utility under the bill must secure a certificate of public convenience and necessity even when using service for municipal purposes only. It was suggested that an election regarding municipal ownership should be held not less than four months after the vote by the municipal council on the question, but no such provision was made in the draft bill on account of the radical differences in the policies of the several states upon this question. The point of providing against the cost of severance when only part of an existing utility property was taken over by a municipality was raised. It was considered important, but its determination was said to depend largely on the local law.

COMMUNICATIONS

The Code of Principles

STONE & WEBSTER
BOSTON, MASS., Nov. 12, 1914.

To the Editors:

I thank you for the copies of the "Code of Principles" of the American Electric Railway Association. Each of the ten articles is so concise and expressive that the code cannot fail to make a deep impression on everyone who reads it. I hope that the code will reach the same prominence that the "safety first" movement has already attained in this country.

I should be glad to see a copy of these ten principles posted in every power station, every electric car and every voting booth in the United States. If the people of this country can be brought to realize clearly that their own prosperity and that of their cities and towns depend largely upon their public utilities then that spirit of antagonism which is now so common will no longer exist. The prosperity of any community and the corporations that serve it are inseparably linked. A full understanding of this by the people and the companies will result in co-operation and avoid dissensions.

When the electric railroad was first developed and introduced, every city and town was ready to offer inducements to capital to invest in their city, and the advantages to the community were clearly recognized. It was a wise policy and made it possible for the United States to quickly build up for the people the best systems of local transportation facilities in the world.

These systems are still needed, and further development of them is imperative if our country is to grow. The present hostile attitude of many communities has been bred plainly by a misunderstanding of the true conditions. The more prominence that is given to this "Code of Principles" the more clearly the public will come to understand what the true conditions really are.

CHARLES A. STONE.

BOSTON ELEVATED RAILWAY
BOSTON, MASS., Nov. 10, 1914.

To the Editors:

The "Code of Principles" adopted by the American Electric Railway Association at its recent convention represents a well-considered attempt to set before the industry and the public in condensed form ten fundamental points of view designed to be useful in public relations. Every effort to bring about a better understanding of the mutual obligations of the companies and of the public is commendable, and such an expression of rights and responsibilities will tend to clear the air in many localities. The code in general seems applicable to both small and large companies, and its usefulness should thereby be enhanced.

Without criticising the intent of the separate items, it would seem that greater emphasis should be laid in the future upon reasonable wages and upon the payment of a reasonable return on the investment as the foremost essential of successful public utility management. The whole scheme of private ownership hinges upon the latter. Efficient service is unquestionably desirable from every point of view, but it should not be forgotten that the best modern facilities are closely related to a reasonable return on capital. The provision of the most advanced standards of service depends directly upon the prospect of a fair return, which is only another way of saying that prosperous electric railway companies are a fundamental necessity to sound transportation development under a régime of publicly regulated private enterprise.

The code covers a broad range of subjects which cannot be discussed adequately in a few words. Its emphasis upon the detrimental effect of short-term franchises upon civic welfare and growth and the desirability of divers methods of valuation in appraisals is well taken. The more angles from which the latter subject can be viewed the less likelihood there is of a one-sided conclusion. The clause pointing out that electric railways, being public servants regulated by public authorities, should be protected against excessive demands of labor and strikes will be generally conceded within the Association. Just how this can be brought about is the problem, and this portion of the code will have served a good purpose if it leads to practical results. The code wisely does not attempt to settle the problems of the industry in detail, but it furnishes a starting point for much valuable discussion, such as Mr. McCarter has contributed to the Nov. 7 issue of the ELECTRIC RAILWAY JOURNAL, pages 1047-1049.

Some of the principles laid down have been practised in Massachusetts from the early days of commission regulation, notably the issuing of securities on the basis of a fair capitalization; the safeguarding of the public interests by the authority given to the regulative body; State as differentiated from municipal supervision; and the full publicity of sources and amounts of receipts and expenditures. In the recent Middlesex & Boston rate decision of the Massachusetts Public Service Commission the right of capital to a living wage is also set forth in terms generally harmonious with the spirit of the code. It is to be hoped that the truths there embodied will find widespread popular acceptance.

WILLIAM A. BANCROFT, President.

WEST PENN RAILWAYS
CONNELLSVILLE, PA., Nov. 4, 1914.

To the Editors:

I wish that you would send me eight extra copies of the "Code of Principles," published as a supplement in your issue of Oct. 31. I want to have them framed and hung in several of our most important waiting rooms. I believe that the principles in this code will be appreciated and thoroughly understood by a large percentage of the traveling public and will assist in improving the relations between the electric railway companies and the public.

M. A. COFFEY,
Superintendent of Transportation.

[EDITORS' NOTE: We have on hand a number of extra copies of the supplement to our issue of Oct. 31, containing the "Code of Principles," and will supply these gratis as long as they last to electric railway companies desiring to post them in public places.]

The Revival of the Flagging Rule

ILLINOIS TRACTION SYSTEM
SPRINGFIELD, ILL., Nov. 2, 1914.

To the Editors:

Referring to your editorial headed "Revival of the Flagging Rule" and previous articles concerning the same question, all of which have been carefully considered by the writer, we have come to the conclusion that almost everybody who has had to do with this particular question seems to be somewhat mixed. The argument is, as we see it, what will a train crew do when finding a block signal set at danger, with all means of communication with the dispatcher cut off and with a right to proceed so far as time-card rights are concerned. Our answer to this proposition is that they should wait the number of minutes necessary for a train under reasonable conditions to arrive, or come from the next siding ahead, after which they should proceed carefully under the protection of a flag where the same should be necessary—that is, around curves, up grades, or over any part of the track where the vision is obscured. This should, however, apply only to roads that are equipped with block signals. An occurrence of this kind in the present day is very rare. I know of no such happening on this line since the signals have been installed.

With reference to the flagging rule in the 1909 book of rules, which was intended for non-signalled roads, I will say that, when the 1911 revision of interurban rules was being discussed, this particular rule brought out considerable argument both for and against it. It was finally decided that a rule which permitted a train crew to flag itself beyond a positive meeting point (such as that appearing in the 1909 code) was not only bad practice, but unreasonable. Also, unless it was carried out with the best of judgment, the rule was unsafe, and hence it was eliminated in the revision of rules in 1911.

Unless the telephone lines are out of use or destroyed for some considerable distance, or in other words, for a number of sidings, there is hardly an emergency which can arise that will delay the operation of trains very seriously. The ordinary telephone trouble does not delay trains to any extent, as it is seldom that trains on the average interurban railroad are off time. When they are off time to any extent there is generally some unusual reason for it and provisions are easily made to straighten it out one way or another. Considering this, we feel that it would be much better to delay a train a reasonable length of time than to take a chance of having trains meet on the main line (even though no damage was done), as this would at least create considerable comment from passengers and would naturally advertise the road and its methods of operation.

With proper supervision we can see no argument for the flagging rule as it was in the 1909 book of rules. From this you can readily see our position in reference to the flagging rule as we understand it in the operation of signals. We know of no rule in the A. R. A. code of rules which permits a train crew to flag itself out of a meeting point given by train order or time card, although the train may move under the protection of another train which has train-order or time-card rights, and consequently, we do not believe that the interurban code of rules should contain a flagging rule.

C. F. HANDSHY, Assistant General Manager.

Indexing Technical Information

MACON, GA., Oct. 30, 1914.

To the Editors:

Since the publication in the ELECTRIC RAILWAY JOURNAL for Oct. 3 of Mr. Alvord's article on "How to Use the Technical Journal," a number of short items have appeared in technical papers describing various filing systems. All of these have merit and prove that engineers and other technical readers have given much thought to preserving or recording the material that interests them, the principal object being to render such matter serviceable and accessible. Where a man is permanently located, and has the facilities to keep them up almost any filing system may be made as serviceable and expansive as desired, but the work must be conscientiously carried out in all of its detail for otherwise such systems frequently become a hopeless muddle.

But the reader who keeps his files up through his own individual effort, and who is confronted with the necessity or inclination to keep them in a compact and even portable form, soon finds the various card indexes and filing systems a burden to be discarded because of their bulk or of the labor necessary for their upkeep. Nevertheless, he feels the need of some form of taking care of certain data in an economical and quickly accessible manner. This one feature, accessibility, is perhaps the keynote to the whole problem. The purpose of this article is to describe a system that not only is accessible but is also compact and simple to maintain.

The illustration shows a file that has been in constant use for nearly ten years, holding many hundreds of valuable clippings, photographs, small drawings, cuts, typewritten sheets, etc., put up in a shape sufficiently portable to be carried in an ordinary suit case, yet admitting expansion or contraction to any desired degree. Scarcely any of the original matter remains in this particular case, as it is constantly being discarded for fresher or more desirable data, the prime object being to retain a compact working library of such material. Yet the matter discarded has not been lost track of and may readily be located in any of the larger libraries located about the country.

The elements of the system are simple and inexpensive, consisting of (1) a 600-page book in limp leather binding, the first fifty pages being alphabetically indexed from "A" to "Z" and the rest numbered consecutively, and (2) a dozen or more grip files or pasteboard covers having flexible backs with two pins or spiles with a covering clamp to bind the filed sheets together, a device more satisfactory for its purpose than any of the loose-leaf ring binders. These files are made to accommodate ordinary correspondence paper, but will readily take the large pages of the technical journals such as ELECTRICAL RAILWAY JOURNAL and the *Enginering News.* These pages usually have sufficient margin to admit trimming three sides to a template, leaving the inside margin for binding. Larger material may be folded, leaving one edge projection for binding, while small clippings may be pasted either singly or in groups on ordinary typewriter paper and then inserted. No special punch is necessary, although one adds to the neatness of the binding, as each cover contains a small flap that may be turned down over the edge of the sheet to be bound, and holes may be punched by pushing the sharp point of a hard lead pencil through the two eyelet holes provided for that purpose. These files cost 15 cents each, less in quantities, and may be obtained from almost any stationer.

LEATHER-BOUND PERMANENT RECORD BOOK AND SPECIAL FILES FOR HOLDING DATA

In this file each cover represents an individual subject or group of subjects, and each cover carries in the space provided an index letter and the title of its volume as

Volume A—Personal Clippings.
Volume B—Steel Construction (all kinds).
Volume C—Electric Railway Data.
Volume D—Concrete Construction.
Volume E—Architecture.

This lettering is continued for as many volumes and general or special topics as desired. It has the advantage of holding all material relating to that particular topic tightly bound in that volume, but no attempt toward further classification is made in these covers. Each sheet as entered is given the next higher number, page 1 being in the back of the book and the highest number always on top. To facilitate indexing, a small red margined Dennison sticker is attached in the upper right-hand corner and on it is placed the index number, volume and page, as 54 C 201, the first figure referring to the page the article is indexed on in the index volume.

In reading the technical papers three classes of material are found: (1) That which you have no desire to keep or refer to; (2) that which you have no desire to keep but which you do not care to lose track of altogether; (3) that which, at the time of filing, you think is worth keeping for future reference. The first is, of course, discarded, the second is recorded under the proper heading of the index before discarding or being placed in the library, the name of the article, the publication and date being entered as described further along, while the third class is clipped and filed in the volume assigned to that group of material. For instance, an article describing the Dallas street railway shops will be placed in volume "C," which in this case contains electric railway data, and is also recorded in the index with the addition of the volume letter and page number.

Now suppose it is desired to locate any or all of the material filed or recorded on car shops, we turn to "E" in the index where we find,

Electric Railway—Track ....page 51
Power Plants ....page 52
Carhouses ....page 53
Car Shops ....page 54

or under "C" we find,

Car Shops—Steam Roads ....page 44
Electric Roads ....page 54

This is a portion of the general index to the whole system, and once established requires no further attention except to add an occasional new sub-title.

Turning to page 54 we find the heading "Electric Railway Car Shops" and under it,

Bedford Shops, *Chicago Tribune,* Jan. 3, 1910.
A. C. C. L. Shops, *Eng. News,* June 6, 1912.
Macon Ry. & Lt. Co. Shops, *Eng. & Contg.,* May 13, 1914, Vol. A, 106.
Dallas Street Railway Shops, ELECTRIC RY. JR., Sept. 19, 1914, Vol. A, 201.

Each page of the index volume is devoted to some sub-title and on it we find recorded articles which have not been retained but which can be readily located if we care to go to the trouble. We can also locate in our own file the article or articles that have been retained. In every case the volume letter and page number are recorded in pencil to permit erasure should the article in question be removed from the file, but in any case the title and location of the original recorded in ink are retained. A 5½-in. x 9-in. 600-page book will be sufficient for a glossary of all the material the average man will care to index himself in a lifetime, while his filed material can be expanded or contracted as suits his fancy.

The description of this method may appear formidable, but in reality hardly anything simpler can be devised. The preliminary index or skeleton is permanent and the only entry made, whether the article is filed or simply recorded, is the one line entry under the proper sub-heading, no further cross-indexing being necessary as that has already been taken care of. A decimal system of numbering may be used but the advantages are hardly worth the extra effort. As the volume letter and page number readily locate it, material does not even need to be grouped in the files, except as such grouping adds to the convenience of having one volume devoted to one subject. Nor does a temporary suspension of interest in filing and indexing serve to disarrange the file which requires a surprisingly small amount of time to keep up. Also any single unit of the file may readily be split up or rearranged, as the page numbers are in pencil and these constitute the only part of the record to be changed.

CARL H. FULLER,
Formerly Engineer of Maintenance of Way,
Macon Railway & Light Company.

British See Opening for Railway Materials

According to *The Electric Railway and Tramway Journal* of recent date, the principal German markets for railway material in 1912 and the aggregate amount sent to each were as follows: Dutch East Indies, £518,900; Turkey, £473,200; Argentina, £319,100; Sweden, £303,700; Switzerland, £288,000; Netherlands, £297,600; Chile, £193,900; Brazil, £181,100; United Kingdom, £180,100; Japan, £166,900, and Denmark, £150,400. Divided according to kind of material, the German exports for rails in 1912 to all markets amounted to £2,900,600; steel railway ties, £763,800; angle plates and base plates, £329,000; fish plates, screws and wedges, bolts, gage bars, clamp plates and spikes, £250,000; metal fittings and buffers, £75,400; railway switches and signal parts, £119,200; carriage and buffer springs, £92,900. The most important item exported was rails, accounting for fully one-half of the total.

In comparing the British and German exports in rails, it is stated that in India and Australia the British hold an overwhelmingly strong position, but in South Africa their position is not so strong, although they already hold four-fifths of the trade. In Egypt, Portuguese East Africa and Argentina, the British share is larger than the German. In the European markets and in the Dutch East Indies the British have hitherto hardly been represented. In the case of chairs and ties, the position is practically the same as with rails—a strong position in British colonial markets and Portuguese East Africa and a weak position elsewhere. It is estimated that the aggregate value of the trade in railway materials which may be diverted from Germany and Austria-Hungary consists of £179,400 in the United Kingdom markets and £3,849,000 in colonial and neutral markets, or a total of £4,028,400.

Second Issue of "The Americas"

The National City Bank has just published the second, or November, issue of its magazine entitled "The Americas." Some of the most interesting articles are as follows: "A New Application of Trade Diplomacy," by William C. Redfield, Secretary of Commerce; "Financial Conditions in Argentina" and "The First Effects of the European War," by R. O. Bailey; "The Present Best Policy of South American Trade," by John Barrett, director general of the Pan American Union; "Organizing to Reach the Merchant"; "The South American Commission House" "Using the Individual Salesman"; "The Advantage of Co-operation in Latin-American Credits," by James Matthews, credit manager National City Bank, and "Banking Acceptances and Dollar Credits."

One article describes the efforts of England to secure the commerce of Germany through such means as the formation on Oct. 8 in London of the Institute of Commerce. The French also hope to secure new markets in South America. Mr. Bailey says that influential Americans already established in Argentina are reported to be opposed to an increase of American trading. An effort six months ago to establish an American Chamber of Commerce in Argentina is said to have failed on account of a fancied infringement of established rights.

The National City Bank's branch at Buenos Aires was formally opened at 321 Calle Rivadavia on Nov. 10 under the management of John H. Allen.

General Outlook in America

In his presidential address on Nov. 12 before the convention of the Investment Bankers' Association of America at Philadelphia, President George B. Caldwell, vice-president Continental & Commercial Trust & Savings Bank, Chicago, Ill., said that Americans should hold steadfastly to a belief in our banks, our securities and our government, as well as in American ability to overcome conditions that three months ago seemed insurmountable.

In enumerating seven things about which Americans should be hopeful, Mr. Caldwell mentioned American neutrality and peace, the annual surplus of about $10,000,000,000 of agricultural products to sell and the stimulus being received by American manufacturers on account of demands from abroad. In regard to the repurchase of a large amount of securities from Europe Mr. Caldwell said that it would be done at a very low price, and moreover, would have to be accomplished but once.

Moreover, speculation in this country was at a low ebb when the war started, and business was being done on a 6 per cent money market, so that it was impossible to drop from a very high level and greatly to demoralize business. Mr. Caldwell also believed that after ten years of agitation the United States is apparently approaching the time when people will not continue to listen to attacks upon big business and constructive wealth. They are beginning to realize that their welfare depends upon the welfare of those companies in which their savings are invested. As a last reason for optimism Mr. Caldwell observed that the new banking and currency act will soon release a large amount of money now in reserve, more than enough to make the early retirement of clearing house certificates and emergency currency possible, thus putting the banking houses of the country in a position they held July 30, 1914.

In Mr. Caldwell's opinion, every possible precaution is being taken in America to minimize the evil effects of the European war, and it now seems possible that the loss to American enterprise will be confined to a shrinkage of income with little or no encroachment upon capital. Some see in the present situation a long siege of calamity, but with new tools in the form of new laws to work with, the man with power of analysis and foresight born of experience knows that it is always possible to turn every advantage into a favorable condition for trading. Events are rapidly transpiring to bring about conditions more nearly normal.

The investment banker, according to Mr. Caldwell, has been for all time the medium through which secured credits were purchased and distributed, and on account of his organization, his ability to mobilize capital and his optimistic efforts and usefulness, he must continue to be recognized as most useful to society. Temporarily restrained, he will resume his activities and usefulness as quickly as the machinery can be put in order and the banks of the country give the word. In behalf of the Investment Bankers' Association, Mr. Caldwell says it does not lack in individual energy or initiative with which to meet the future.

American Association News

Opening of the New Association Year is Marked by Many Committee Meetings—Engineering and Transportation & Traffic Associations Have Selected Subjects Which Will Be Announced Soon—Index Bureau Subscription Is In Danger

The present week has been a busy one at association headquarters as the following committee meeting schedule was adhered to:

Monday, Nov. 9; committee on compensation for carrying United States mail, American Association; committee on subjects, Engineering Association.

Tuesday, Nov. 10; executive committee, Engineering Association; committee on annual dinner, committee on subjects and special membership committee, American Association.

Wednesday, Nov. 11; committee on subjects, Transportation & Traffic Association.

Thursday, Nov. 12; executive committee, Transportation & Traffic Association.

A meeting of the national joint committee on electrolysis was also held on Friday, Nov. 13, at the headquarters of the American Institute of Electrical Engineers. The association has adequate representation on this committee.

A meeting of the joint committee on overhead and underground crossings is scheduled for Tuesday, Nov. 17.

The association is also interested in the meeting of the A. I. E. E. committee on standards which is being held in New York to-day.

AMERICAN ASSOCIATION COMMITTEES

At the meeting of the committee on compensation for carrying United States mail, held on Monday, there were present the following: Capt. A. R. Piper, Brooklyn Rapid Transit Company, chairman; W. H. Collins, Fonda, Johnstown & Gloversville Railroad; T. C. Cherry, Maryland Electric Railways Company; P. N. Jones, Pittsburgh Railways, and J. H. Neal, Boston Elevated Railway Company, representing H. P. Lyons.

The committee prepared information for the use of the joint committee of the House of Representatives and the Senate of the United States on postage on second-class mail matter and compensation for the transportation of mail, as requested by Senator Bourne, chairman of the committee. The report contains statistical information relating to the transportation of mail matter by electric lines and it was immediately forwarded to Senator Bourne.

The special committee on membership appointed by the executive committee of the American Association at Atlantic City held a preliminary meeting on Tuesday. Those in attendance were L. S. Storrs, Connecticut Company, chairman; C. L. Henry, Indianapolis & Cincinnati Traction Company; James H. McGraw, McGraw Publishing Company, Inc.; S. K. Colby, Allen & Peck, Inc., and J. H. Hanna, Capital Traction Company, representing L. P. Crecelius. The committee is formulating a report to be presented later to the executive committee of the American Association.

JOINT MEETING OF AMERICAN AND MANUFACTURERS' ASSOCIATIONS COMMITTEES

A joint meeting of the subjects committee of the American Association and the committee on annual dinner of the American and Manufacturers' Associations was held on Tuesday to consider the details of the mid-year meeting and the annual dinner. As the decision had already been reached that the mid-winter meeting should be held in Washington on Jan. 29, and that it should consist of but one session for the presentation of addresses, the work of the committee was considerably simplified. The committee decided to hold the dinner on the evening of Jan. 29 and considered at length the program for the annual meeting and the dinner. A tentative program was prepared and speakers will be invited at once to participate. Due announcement of the names of these will be made. The committee decided that there should be no reduction in the number of addresses from that usual at mid-winter meetings and that the discussion should continue until all of the speakers had been heard. The committee plans to utilize the opportunity for securing prominent speakers afforded by the fact that the meeting will be held in Washington.

The following committee on arrangements for the dinner was appointed to look after details of this feature: J. H. Hanna, Capital Traction Company, chairman; W. F. Ham, Washington Railway & Electric Company; S. K. Colby, Allen & Peck, Inc.; C. C. Pierce, General Electric Company, H. G. McConnaughy, Dearborn Chemical Company, and E. B. Burritt, secretary. This committee will have general charge of the arrangements for the banquet, but the details will be in charge of a sub-committee to be known as the committee on arrangements, comprising Messrs. Burritt and McConnaughy.

A committee on transportation was also appointed consisting of Bertram Berry, Heywood Brothers & Wakefield Company, chairman; J. A. Kucera, ELECTRIC RAILWAY JOURNAL, and Harlow C. Clark, *Aera.*

Those in attendance at this meeting were C. L. Henry, Indianapolis & Cincinnati Traction Company; J. H. Hanna, Capital Traction Company, representing L. P. Crecelius, president of the Engineering Association; William Tichenor, Terre Haute, Indianapolis & Eastern Traction Company; Harlow C. Clark, *Aera;* C. C. Pierce, General Electric Company; S. K. Colby, Allen & Peck, Inc.; Bertram Berry, Heywood Brothers & Wakefield Company, and E. B. Burritt, secretary A. E. R. A.

ENGINEERING ASSOCIATION COMMITTEES

At the meeting of the committee on subjects held on Monday there were present: John Lindall, Boston Elevated Railway, chairman; J. H. Hanna, Capital Traction Company; Martin Schreiber, Public Service Railway; L. P. Crecelius, Cleveland Railway, and F. R. Phillips, Pittsburgh Railways.

The committee drafted a report assigning subjects for investigation by different committees for the coming year for consideration of the executive committee, which met on the following day.

The executive committee met on Wednesday with the following in attendance: L. P. Crecelius, Cleveland Railway, chairman; John Lindall, Boston Elevated Railway; F. R. Phillips, Pittsburgh Railways; H. F. Merker, East St. Louis & Suburban Railway; G. W. Palmer, Bay State Street Railway; W. G. Gove, Brooklyn Rapid Transit Company; J. H. Hanna, Capital Traction Company, and Martin Schreiber, Public Service Railway.

The committee approved the recommendations of the committee on subjects, and these will be announced as soon as the appointment of committees has been completed. All of the committees of last year were continued and a new special committee on lightning protection was appointed. The committee voted to request from the American Electric Railway Association the sum of $4,000 to carry on the work for the coming year. A set of rules was also drafted as a guide in the consideration of matters jointly with other associations.

TRANSPORTATION AND TRAFFIC ASSOCIATION

The committee on subjects of this association met on Wednesday and formulated plans for the year for submission to the executive committee, which met the following day. There were present: E. F. Schneider, Cleveland, Southwestern & Columbus Railway, chairman; H. C. Donecker, Public Service Railway, and L. H. Palmer, Harrison Williams Company.

The executive committee of the same association met on Thursday to consider the report of the committee on subjects. There were present: M. C. Brush, Boston Elevated Railway, chairman; R. E. Danforth, Public Service Railway; T. C. Cherry, Maryland Electric Railways; H. A. Nicholl, Indiana Union Traction Company; C. D. Emmons, Chicago, South Bend & Northern Indiana Traction Company; L. H. Palmer, Harrison Williams Company; E. F. Schneider, Cleveland, Southwestern & Columbus Railway; H. C. Donecker, Public Service Railway, and E. B. Burritt, secretary A. E. R. A.

The committee approved the report of the committee on subjects, the details of which will be made public shortly, and considered carefully the personnel of the several committees to insure the continuation of the excellent work of former committees. It was decided that reports of committees should be received on May 1 to insure proper consideration before the convention. The appointment of a committee on standards, to comprise eleven members, was authorized. This will consist of the chairmen of the committees on rules, passenger traffic, express and freight traffic, construction of schedules and time-tables, and training of transportation employees, and of one member at large from each of these divisions of transportation work, and of the chairman who shall also be chosen at large. It was further recommended that a joint committee with the Claims Association be appointed to consider the training of transportation employees, particularly with a view to utilizing the experience of the claims departments with accidents, without interfering with discipline.

ULTIMATUM ON THE INDEX BUREAU SERVICE

At the Atlantic City convention the executive committee of the American Association voted to discontinue the subscription to the Hooper-Holmes Bureau service on Dec. 31 unless much greater use is made of it than at present by the member companies. Circular letters are now going out from H. V. Drown, chairman of the Claims Association committee on index bureau, and from the central office, calling attention to the situation and to the facts underlying it. From these letters it appears that the small companies in particular are not using the bureau as they profitably could, and that those who are using it are receiving great benefit. Under the arrangement with the bureau members of the association have the privilege of filing reports of accidents and receiving in return, for a nominal consideration, reports upon such cases as involve individuals known to the bureau. There are now on file with the bureau more than 3,000,000 records, and the number is increasing by 500,000 each year.

Meetings of Anthony N. Brady Medal Award Committee

Meetings of the committee of men not identified with railway operation appointed by the American Museum of Safety to award the safety medals founded by the relatives of the late Anthony N. Brady were held in New York on Nov. 12 and 13. Those present were: Bion J. Arnold, Chicago, chairman; Frank J. Sprague, New York; James H. McGraw, New York, and W. H. Tolman, secretary-director of the American Museum of Safety. The committee met to award the medals under conditions prescribed by the committee of the American Electric Railway Association comprising A. W. Brady, Indiana Union Traction Company; C. S. Sergeant, Boston Elevated Railway, and Frank Hedley, Interborough Rapid Transit Company. The data furnished by a number of electric railways, which had complied with the request of the committee for information regarding accidents and the means taken to prevent them, were considered by the committee and will have further study. The competition has naturally awakened great interest and the committee was pleased to note how widespread and substantial is the safety movement.

Eleven Fundamental Principles

P. W. Brooks & Company, New York, have recently issued an interesting pamphlet dealing with eleven fundamental economic principles that should be followed by an investor in buying securities. The value of public utility bonds is tested from the eleven standpoints. These are demand; relation of supply and demand; efficient management; supervision by commissions; financial analyses of condition; attitude of national banks; successful operation; test by time, panic and war; freedom from competition; small denomination of bonds and certificates; and a yield, proportionate to the cost of living. In the light of each point, all public utility bonds are said to qualify as a safe and substantial investment.

The point of successful operation is discussed in connection with net earnings and the risk of receivership in per cent of capital invested. For the last thirty years public utilities have earned 8.45 per cent, as compared to 4.25 per cent for steam railroads and 7.79 per cent for industrials. The risk of receivership for the same period has been 1.84 per cent for steam railroads, 2.07 per cent for industrials and 0.37 per cent for public utilities. During the period of panic and its effects from 1907 to 1911, the net earnings of public utilities showed an increase of 60 per cent for gas and electric companies, 20 per cent for electric railways, and only 5 per cent for steam railroads. It is stated that in no other class of securities is there such a large proportion of bonds of $100 and $500 denominations. This gives public utility bonds two important advantages, in that they offer 5 and 6 per cent to the investor on savings which have not yet reached the amount necessary for investment in other bonds, and they have a very broad direct distribution. This return of 5 and 6 per cent, moreover, is accompanied by a high degree of safety.

The business of public utilities is said to be growing more than twice as fast as the railroad business, and to meet the increased demands of the public for public utility services it is estimated that $1,200,000,000 of new capital per year will be required.

The work of D. W. Merritt, chief despatcher of the San Antonio (Tex.) Traction Company, was described and illustrated in the San Antonio *Light* recently.

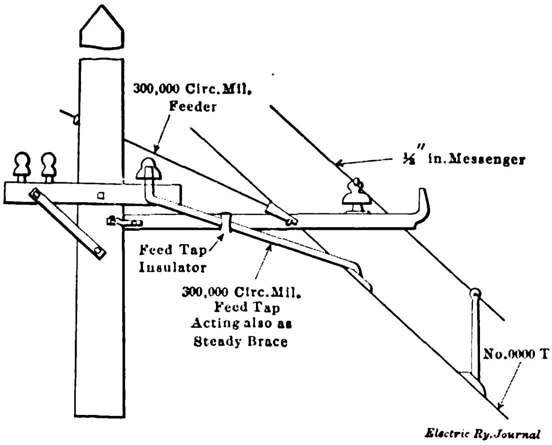
A Combined Steady Brace and Feed Tap

BY E. S. ELLIS, SUPERINTENDENT OF CONSTRUCTION CLEVELAND, ALLIANCE & MAHONING VALLEY RAILROAD, ALLIANCE, OHIO

The Cleveland, Alliance & Mahoning Valley Railroad for a year and a half has been operating a 19-mile line between Alliance and Ravenna. Last year it began the construction of its Ravenna-Warren division, a distance of 17 miles, and it is now constructing between Newtown Falls and Warren an 11-mile section. The company also proposes to extend its lines northward from Ravenna to and through Hudson, Twinsburg, Falls Junction and Randall to Cleveland, a distance of about 31 miles. Even the city trackage is on right-of-way.



COMBINED STEADY BRACE AND FEED TAP

We had much trouble with the steady braces and feed taps on our catenary line until the writer hit upon the following scheme for combining the feed tap and steady brace in one. As shown in the accompanying sketch, the same feed tap insulator as used for ordinary feed taps is clamped to the mast arm. With this insulator we use a piece of feeder to make the tap, the same piece also acting as a steady strain. A standard ear is screwed on the wire and clamped to the No. 0000 trolley to complete the connection.

Detroit Paint Shop Work-Card System

BY C. L. KELLER, ASSISTANT MASTER MECHANIC DETROIT UNITED RAILWAY

A change from the flat-rate-per-day plan of payment to the piece-work system necessitates a corresponding change in timekeeping methods, which may result in the error of "too much system" if not carefully studied and safeguarded. A piecework timekeeping system in which both accuracy and simplicity are embodied is now in force in the Highland Park shops of the Detroit United Railway. Two printed forms are in use, and, in the course of the eight or nine months that the paint shop has been working on the piece-work basis, we have had no operations that could not be accounted for on them. An additional advantage is that timekeeping for day work or piece work can be recorded on the same time card.

The operation or work card is 4 in. x 6 in. in size, and is printed only on one side of a light cardboard, which is just heavy enough to withstand a little rough handling. As illustrated, the upper left hand corner is left blank for the imprint of the time stamp at the commencement or completion of a job, and the opposite corner contains blanks for entering the car number and type. For convenience the cars are designated as single or double-truck city cars and interurban cars. These are further subdivided into a number of different types, payment for the work done being regulated by the type to which the particular car is assigned.

CORRECT James Smith Foreman.

PIECEWORK TIME CARD, DETROIT UNITED RAILWAY car or the number finished by a workman is indicated opposite the word "special" at the bottom of the card, as is any other notation that may be desired.

The piece-work time card, which is the other form shown, is merely a blank for assembling the time of one man for one day. When filled out, this form contains all the necessary information for wage or cost purposes. The card is printed on light-weight paper, since it is only handled by the time clerks and not by the shop workmen.

METHOD OF USING FORMS

Workmen, upon arrival at the shop, ring in at the time clock, and then proceed to the foreman, where they receive a work card on which the time of beginning is stamped and the car number on which they are to work is indicated. One of the operations listed in the small rectangles is also checked with a pencil to indicate the particular work to be performed. Upon the completion of the work assigned it is inspected by the foreman and if found satisfactory he affixes his initials at the bottom of the work card above the word "approved," after which he turns the card over and writes the car number and operation for the next job. The workman then proceeds with the card to the time clerk, who stamps the finishing time upon it and issues a new card from the data on the back of the old one.

From the information contained on the completed card the clerk can compute the time occupied in performing the operation. This is entered upon the workman's daily time sheet with the car number, class of work and on what plan of payment the work was done. At the close of each day these time slips are delivered to the timekeeper, who inserts the rates and calculates the amounts due, and distributes them to their proper accounts. From the foregoing, as can readily be seen, the work card is virtually a written order to the employee. From it, he is enabled to keep an accurate account of his work, and if any question arises there is really no reason for an argument, since the entire record may be produced and verified.

Manufacture and Cost of a Built-Up Mate

BY R. P. WILLIAMS, INSPECTOR OF SPECIAL WORK BROOKLYN RAPID TRANSIT SYSTEM

The mate shown is our standard for emergency crossovers and branch-offs. It is built up of the Pennsylvania Section 291, 132-lb., or Section 294, 117-lb. rail.

An important feature is the strength of the main rail, the head web and the base being left intact. The raising of the head of the curve rail to the level of the guard of straight rail provides a floor for the wheel flange while passing from the main to the curve rail. The splice bar fit, shown at section *A-A*, and the heavy chock, shown at section *C-C*, make for stability.

In the ordinary built-up mate the base of the main rail is cut away into the web, and as a consequence the rail breaks at this point under heavy travel, or lacking the splice bar fit a shearing action between the main and curve rail loosens the mate and destroys the foundation.

CONSTRUCTION DETAILS OF BUILT-UP MATE USED BY THE BROOKLYN RAPID TRANSIT SYSTEM

Fig. 1 shows drilling and clearance cut for planing; Fig. 2 shows the detail of cuts for the main rail; Fig. 3 shows the cut for the curve rail, the ⅜ in. measured from the inside of the guard being a straight line to the 5-ft. point at the back of the head, and Fig. 4 shows the rails and chock assembled for bolting.

We have had mates of this make in service for more than two years, some of them under our heavIest traffic, without loosening. The cost of construction follows:

Labor	
Cutting rail	$1.47
Shaping clearance	1.05
Bending	1.15
Drilling	1.95
Planing	4.65
Fitting and bolting	1.35
Fitting chock	.35
Grinding	1.70
Supervision	1.50
Total labor	$15.17
Material	
Rail	$25.92
Chock	2.00
Bolts	.75
Total material	$28.67
Grand total—labor and material	$43.84

Equipment Defects—Control Apparatus and Connections—I

BY C. W. SQUIER, E. E.

The starting of motors from rest and their acceleration to a speed where they can be operated at line voltage form the nucleus of the control problem. To this must be added suitable methods for securing several efficient operating speeds and necessary connections for reversing the direction of rotation, as well as suitable connections for those cases where the motors are to be used as prime movers or for electric or magnetic braking. The motors should be started with the least expenditure of energy and with such uniform acceleration that no excessive loads or undue strains will be thrown on them or other parts of the equipment, and with the maximum current peaks well within the commutating capacity.

In the present articles I shall deal simply with those control problems which arise in the operation of electric cars or trains, as a desirable introduction to the study of troubles that arise in operation. Since the d.c. series motor is the most widely used, only this type will be considered. I propose, further, to confine the discussion to the problems in which the motion of the rotating part of the motor maintains a constant relation to the motion of the driving wheels. The motor then must start from rest and increase its speed as the car or train increases in speed.

MOTOR ACCELERATION

First let us consider the control problem apart from the apparatus or its manipulation by considering several circuit combinations that are essential to the proper control of the motors. The problem of accelerating a motor from rest to full speed consists in starting the motor with a certain amount of external resistance in circuit with it, and then by reducing this resistance or by a series of combinations of the resistance, increase the impressed emf at a uniform rate. The greater the number of steps in the regulating rheostat the less will be the current peaks and the more uniform will be the acceleration.

In deciding on the number of steps, the first point that should be considered is the maximum allowable variation in the torque of the motors during acceleration. The average torque is obtained by considering the average acceleration that it is desired to maintain, and this must be a certain amount in order to fulfil the operating conditions laid down. Therefore, the accelerating force will be a certain constant amount upon which will be superimposed another amount composed of a succession of impulses in the nature of blows of greater or lesser intensity, depending on the number of impulses or the number of steps in the regulating resistance. This is indicated in Fig. 1, which shows a current-time curve and a tractive effort-time curve obtained in starting a car with two motors, and accelerating it to a speed where the motors can be operated with full line potential. The average tractive effort per motor required in this case was 1335 lb., and the maximum of 1800 lb. was obtained on the second point. Each succeeding notch of the controller was taken when the current had dropped to 63 amp.

Since the impulses just referred to cannot be eliminated entirely they should be made small enough to give the desired smoothness of operation. For ordinary service the difference between the greatest and least torques of the motors during acceleration should not be more than 40 per cent of the average torque required. For passenger service the comfort of the riders must be considered, and any excessive or sudden jerking is very annoying. The life of the apparatus and of the car itself is affected by the severity of these impulses. Hence control resistances must be so designed that the impulses will be small enough to be within the strength of the apparatus. In freight locomotives any excessive peaks in the torque supplied by the motors will cause the wheels to slip, and such slippage is a very important consideration in starting heavy loads.

RESISTANCE CONNECTIONS

The calculation of the resistance stepping and the number of steps required will be taken up when we consider resistance details. Resistance connections and combinations to increase the impressed emf at the motors affect the controller design, however, and several different methods will be considered.

Series Resistance—A series method of connecting the resistance is shown in Fig. 2. This consists of arranging the total resistance in several groups as *A, B, C* and *D,* with all groups connected in series at the start. This resistance is decreased by short-circuiting sections of it progressively, as indicated by the numbers applied to the contacts or switches which close in the order they are numbered and remain closed until the succeeding ones short-circuit their respective sections of resistance. Fig. 3 shows another method of connecting series resistance. In this case each succeeding switch or contact not only short-circuits its section of resistance, but also the resistance switches or contacts already closed. The arrangement shown in Fig. 2 has the disadvantage of requiring larger and heavier switches or contacts than that of Fig. 3, as each contact when closed must carry the whole current passing through the motors from the instant it is closed until the circuit is opened again. Contrariwise, with the arrangement shown in Fig. 3 each contact carries the whole current only until the next succeeding switch or contact closes. The Fig. 3 arrangement, however, has this disadvantage: if the last switch remains closed for any reason, say when the contacts are welded by excessive heating, all the resistance is short-circuited, while in the Fig. 2 method but one section is short-circuited.

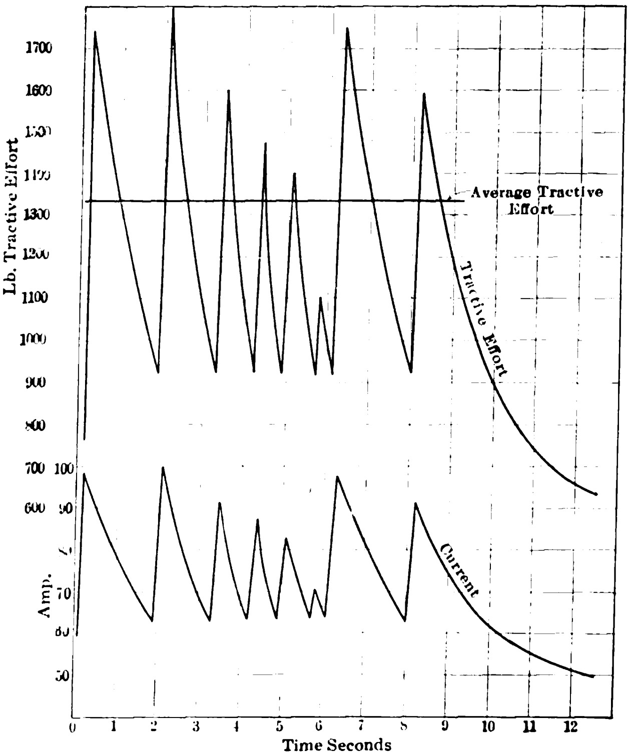

FIG. 1—CURRENT AND TRACTIVE EFFORT CURVES

Parallel Resistance—Fig. 4 shows a parallel method of arranging resistance. This consists of connecting the different sections *A*, *B*, *C* and *D* of the resistance in parallel. The total value of the resistance in circuit is thus decreased, as each section is connected in until finally the last switch or contact short-circuits the whole resistance.

The series methods have the advantage of having all resistance available for heat radiation when operating on the first point of the control, but they have the disadvantage of requiring larger and heavier switches and contacts because each when closed short-circuits its section and must carry the total current passing to the motors. This means that each contact must be of the same capacity as the final short-circuiting contacts No. 5 in the parallel method.

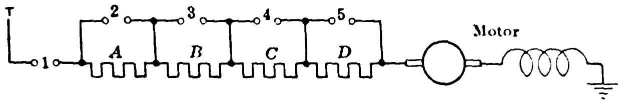

FIG. 2—SERIES METHOD OF CONNECTING RESISTANCE WITH SHORT-CIRCUITING SWITCHES IN SERIES

Series-Parallel Resistance—In an effort to reduce the total number of the contacts or switches and also the number of resistance connections, a combination of both series and parallel is sometimes used with the same control. Fig. 5 illustrates such an arrangement, and the resistance combinations for a five-point controller are as follows:

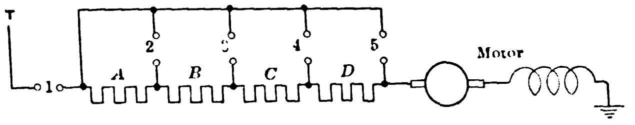

FIG. 3—SERIES METHOD OF CONNECTING RESISTANCE WITH SHORT-CIRCUITING SWITCHES IN PARALLEL

First point—With No. 1 switch closed resistance groups *A*, *B* and *C* are connected in series. Second point—with switches Nos. 1 and 2 closed the resistance is reduced by short-circuiting group *C*. Third point—with switches Nos. 1, 2 and 3 closed, resistance groups *B* and *C* are short-circuited and we have group *A* alone in the circuit. (Before passing to the fourth point No. 2 switch is opened. This does not change the value of the current to the motors as this switch has already been short-circuited by the closing of No. 3 switch.) Fourth point—switches Nos. 1, 3 and 4 are closed, No. 2 remaining open and resistance groups *A*, *B* and *C* are placed in parallel. Fifth point—switches Nos. 1, 2, 3 and 4 are all closed and all resistance is short-circuited.

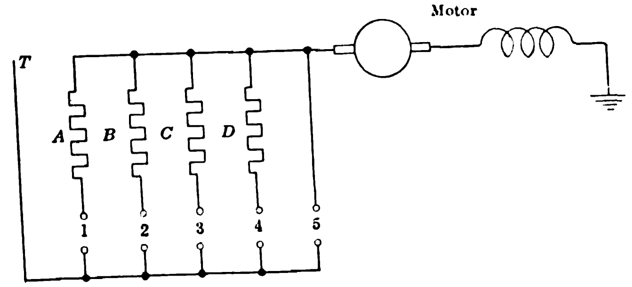

FIG. 4—PARALLEL METHOD OF CONNECTING RESISTANCE

With this series-parallel arrangement of resistance five points of control are secured with but four switches and three groups of resistance, while with the series and parallel arrangements shown in Figs. 2, 3 and 4, five points of control require five switches and four groups of resistance.

Still another resistance combination can be obtained with switches Nos. 1 and 4 closed, leaving the resistance group *C* in circuit. This can be used to advantage when motors are operated in series and parallel combinations, for to obtain the best acceleration it is necessary that the amount of resistance and the stepping should be different with the motors in parallel from what is necessary with the motors in series.

In the diagrams referred to so far I have shown only one motor, but the same connections will apply equally well to combinations of two or more motors by connecting them in series and parallel with the regulating resistance. A resistance common to all motors may be used, or each motor may have its own regulating resistance.

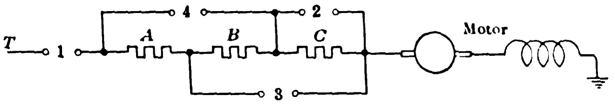

FIG. 5—SERIES PARALLEL METHOD OF CONNECTING RESISTANCE

Chicago Elevated Economy Posters

In order to impress upon the minds of its employees the cost of materials in every-day use, and what it means to the railroad company if they are wasted, the different departments of the Chicago Elevated Railroads have compiled a complete cost record of the various materials in common use. These have been printed in the form of posters which are displayed in conspicuous locations throughout the system. Under a heavy type heading entitled "Material Means Money" the following text matter is contained: "Would you allow a quarter, dime or even a penny to lie around on the structure or to be kicked around on the ground? You are intrusted with material that is just as valuable as the coin and should be as carefully protected. Look at the following prices and be as economical and as careful with all material, whether new or old, as you would be with your own." The following list of materials and their costs are furnished because it was believed that it would be helpful to other companies in compiling economy posters of this kind. The posters are printed in two forms, one for the electrical and track department, and another for the transportation and shop department. Each is displayed where it will receive the most attention from the departments effected. The following is a list of materials and their costs contained on these posters:

TRACK DEPARTMENT

Track spike, 9/16 in. x 5½ in.	$0.01	Signal oil, per gallon	$0.34
Screw spike	.04	Wood alcohol, per gallon	.41
Nut lock, ⅞ in.	.01	Muriatic acid, per gallon	.45
Beveled washer	.02	Turpentine, per gallon	.53
Hacksaw blades	.04	Malleable rail brace	.30
Hook bolts	.05	Malleable rail plate	.47
Lag screws	.05	Angle bars, 26 in. long, per pair	.90
Buttonhead bolt	.06	Plank, 2 in. x 6 in. x 16 ft., each	.46
Track bolts, 4¾ in. long	.05	Tie, yellow pine, 8 ft	1.00
Track bolts, 9 in. long	.09	Tie, yellow pine, 9 ft	1.12
Curve grease, per pound	.06	Guard rail, 6 in. x 6 in. x 24 ft. 8 in.	2.15
Tie plates, short	.11	Guard rail, 6 in. x 8 in. x 24 ft. 8 in.	2.88
Standard joint plate	.14		
Tie plates, long	.16		
Compressor oil, per gallon	.24		

ELECTRICAL DEPARTMENT

No. 4½ porcelain knobs	$0.01	Rubber tape, per pound	$0.60
½-in. x 2½-in. lag screws	.01	3-in. iron battery bell	.25
¾-in. x 3¼-in. track bolts	.02	G. E. No. 50702 lamp sockets	.27
½-in. x 12-in. arc light carbons	.02	No. 0000 clinch ears	.34
Conduit, ½ in., per foot	.04	18-in. splicing ears	1.04
Dry batteries	.15	No. 0000 foot bonds	.35
Weatherproof cable, No. 0000, per foot	.15	No. 0000 16-in. cable bonds	.54
½-in. twist drills	.09	No. 0000 48-in. cable bonds	1.05
Solder, per pound	.20	48-lb. third-rail insulators	.52
23-watt Mazda lamps	.20	Submarine cable, 500,000 circ. mil, per foot	.64
150-watt Mazda lamps	.79	P. & B. paint, per gallon	.55
Inner arc lamp globes	.16	10-amp snap switches	.77
Outer arc lamp globes	.75	Brooklyn strain insulators	.88
Friction tape, per pound	.21		
P. & B. tape, per pound	.30		

Shop Department

Air-hose gaskets	$0.01½

Light hose jumper $2.50 to	3.50
Pyrene fire extinguisher	5.60
Train line jumpers	20.00

Painting Steel Cars

At the November meeting of the Central Railway Club Milton L. Sims, of the Sherwin-Williams Company, stated that the preparation of a steel coach for painting was of vital importance, as the absolute removal of all scale, grease and corrosion was necessary before any protective coatings should be applied. Any idea that paint coatings would stop corrosion when it had once started was incorrect. The safest and most economical method for removing rust was the sand blast for the outside of the cars. For the interior the use of raw linseed oil and benzine or gasoline was recommended in the proportion of one part of the oil to two parts of the benzine, applied with a brush and rubbed down with emery cloth or paper. After the rubbing down was completed, the surface should be washed with gasoline and rubbed dry with rags or waste and was then ready for the priming coat, which in all cases should be applied as soon as possible after the surface has been cleaned. The priming coat was more important than any one that was to follow, except the coats of finishing varnish, and too much care could not be exercised to see that it was done thoroughly, brushed out evenly and every bolt head and joint coated perfectly. The priming coat must spread smoothly under the brush, dry hard, but be elastic enough safely to withstand the contraction and expansion of the steel surface, which varied greatly in different sections of the country.

When the priming coat had dried safely, the next step was to hard-putty and glaze-coat over all rough places. The second coat, or brush surface, which is designed to fit with the priming coat must dry hard but elastic, and should be made from well-known and selected materials. A much heavier bodied surfacing material should then be applied and knifed off, leaving a very smooth surface, which required very much less rubbing to bring the surface up ready to receive the color coats. A more modern and safer method than using block pumice stone and water was to rub the surface down smooth by using emery cloth in connection with equal parts of raw linseed oil and benzine, and then to wash or wipe off with rags or waste and clear benzine or gasoline.

Mr. Sims said this method of surfacing did away with all danger from moisture and prevented the starting up of corrosion where any sharp edges or bolt heads may cut through to the steel. The oil formed a good sealer for the more or less porous surfacing material and provided a safe foundation for the succeeding color and varnish coats.

One coat of specially prepared car-body color should be applied and then a second coat of specially prepared car-body color. The latter should be of an elastic enamel quality, should dry hard with a semi-gloss, but should make an elastic surface suitable for striping and lettering. After this two coats of durable outside finishing varnish should be applied, and the outside of the car would be ready for service. The same priming material should be used on the interior surface, and should then be followed up with the second coat of brush surfacer. The heavy coat of knifing material could be dispensed with, and after the rubbing with emery cloth, oil and benzine had been finished, a suitable ground for graining in imitation of natural woods should be used, and then two coats of elastic rubbing varnish. The latter could be rubbed to a dead finish with rubbing oil and pulverized pumice stone, or polished as desired. This schedule was stated to require thirteen days.

With regard to canvas roofs, Mr. Sims stated that they required a specially prepared roof primer which dried very elastic and did not penetrate clear through the cotton fabric. This prevented the rotting of the fabric, which was sure to occur where too much vegetable oil was used. After the special primer has been applied, special long-life roof paints of any desired shade could be applied. He further stated that the method of painting steel coal cars had changed very materially in the last few years. Formerly all coatings were made very elastic, and very little attention was given to make the first or priming coat dry any differently from the last or finishing coat. Research work on this matter had proved that the method was wrong and that the first or priming coat should, by all means, be constructed so as to dry hard and elastic, using specially treated vehicles for the purpose and such pigments as would be neutral and last the longest. The finishing coats were made more elastic and had more gloss and moisture-resisting qualities.

Electrolysis Survey at Providence

A detailed electrolysis survey was recently completed at Providence, R. I., by Robert L. Brunet, public service engineer of the city, assisted by James A. McKenna, of the city engineering department, with the co-operation of the Rhode Island Company. The greater part of the observations were made with a test car furnished by the company. At various points in the city test stations were also established at which were determined the flow of current in pipes and the voltage drop between pipes and rails. The maximum current found at any of the eleven testing stations employed was 13 amp. At seven stations no current in pipes was observed, the favorable conditions being attributed to the installation of insulating joints, thirty-five of which are now in use. The tests showed that the water mains in the city are on the whole substantially free from stray currents. On recommendation of Mr. Brunet, the company is to install negative cables from the Douglas Avenue terminus to the tracks on Admiral Street and from the Admiral Street terminus to the tracks on Branch Avenue. In his report, Mr. Brunet suggests that the company be formally requested to test its track and bonds yearly, the city conducting a similar yearly investigation on the piping systems. Other recommendations to be carried out from time to time include the installation of pilot wires to determine the over-all potential drop in the track, the determination of potential gradients, use of the negative returns, and yearly excavations and inspections at certain points to determine the integrity of the bonding system.

Light-Weight Cars for Puget Sound

The St. Louis Car Company recently shipped the Puget Sound Traction, Light & Power Company ten double-truck prepayment city cars, which are notable for combining lightness in weight with maximum capacity in transverse slat-type seating. The body measures 38 ft. 4 in. between the corner posts and 49 ft. 2 in. over the buffers, while the width over the sheathing is 8 ft. 4 in. These cars are of the Stone & Webster standard design for city service, but are considerably longer than cars of this design previously built. In fact, in the Puget Sound cars the designer carries out the same underframe and side construction as used on the cars of 26 ft. to 30 ft. length. The side sill angles are 5 in. x 3 in. x 5/16 in., with cross-sills of 3 in. 5½-lb. I-beams. The posts are the company's standard 1½-in. x 2-in. x ¼-in. "T" Carnegie section No. 519, and extend in one piece from side sill to side sill, forming the post and carlin. The outside panel is a girder of 5 32-in. x 29-in. plate extending from center to center of the end sills. A reinforcing plate 5 16 in. x 6 in. x 12 ft. is placed over the bolsters. Cross-sill truss rods are riveted to the side sill angles and have malleable iron struts riveted to the I-beam cross-sills. The layout is for single-end operation with a front platform 4 ft. long and a rear platform 6 ft. long over the dasher, both vestibuled. The seating capacity is sixty. The complete equipment weighs 39,000 lb., the car body alone weighing 18,000 lb.

An interesting feature is the absence of headlining, the roof being formed of ¼-in. canvas-covered Agasote. The two end ventilators are of the Stone & Webster vacuum type, while that in the rear hood and the six on the roof are of the car builders' type. The view of the interior also shows the motorman's cab which is entered by way of a 22-in. sliding door. The cab is finished in mahogany to harmonize with the general interior finish.

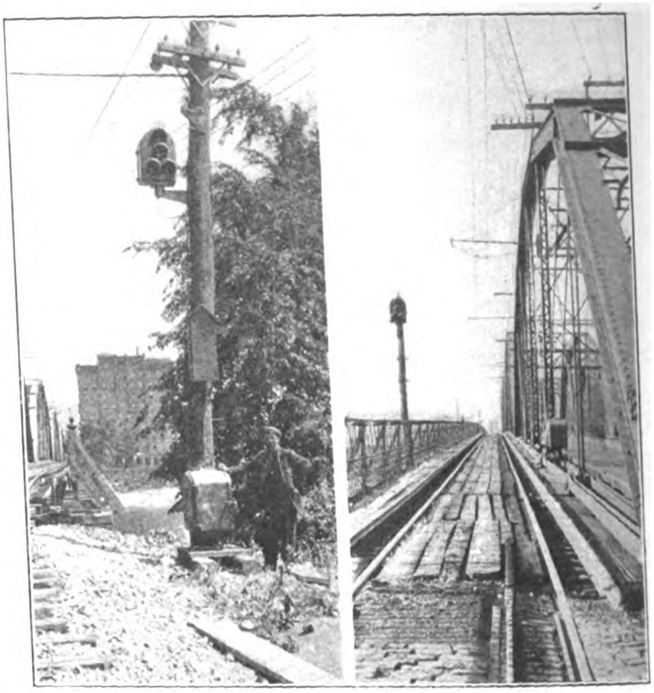
Protecting Traffic on a Single-Track Bridge

The Wilkes-Barre Railways Company is protecting traffic over the Market Street Bridge in Wilkes-Barre, Pa., a distance of 708 ft., with a set of the Type-E signals of the Street Railway Signal Company, Philadelphia, Pa. As the service at this point is almost constant the signals do strenuous duty, cars passing over the bridge at this season of the year at a rate of about 1000 per day of twenty hours. The percentage of failures in six weeks was 0.032, a most remarkable record in consideration of the fact that, under normal conditions, six cars leave the Public Square every ten minutes and pass under the signals in rotation, cars entering the block at the east end at the same time that cars are leaving at the west end. This makes the counting-in and counting-out operations simultaneous,



SIGNALS PROTECTING BOTH ENDS OF BRIDGE, WILKES-BARRE, PA.

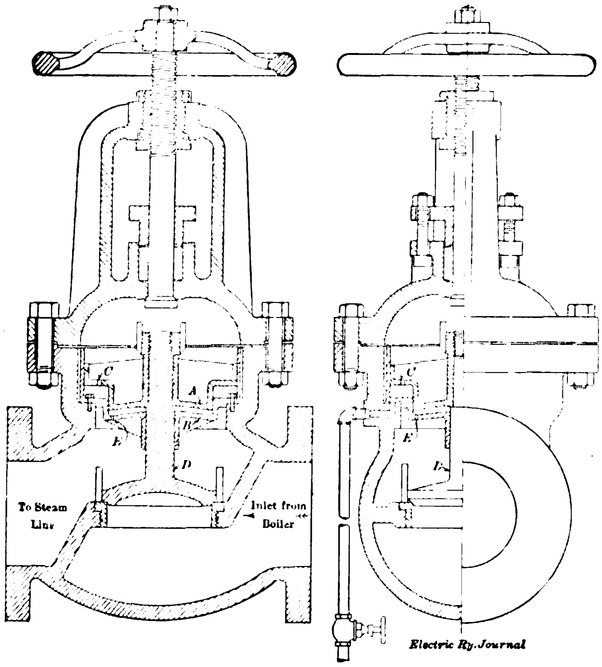
a feature which the Street Railway Signal Company claims to be original with its apparatus.

As the cars come across the bridge into Wilkes-Barre they enter a turnout that will accommodate only three cars. In order to facilitate traffic and avoid possibilities of a tie-up at this point an arrangement has been introduced whereby the closing of a switch will cause the signal at the west end of the bridge to go from permissive to stop after the passage of the three cars into the block, this indication holding until all cars pass out of the block. The illustrations on page 1110 show how the signals are mounted. At one end of the bridge the aspect case is on the existing pole, with the relay case at the bottom of the same pole. At the other end the aspect case is on a special pole with the relay located at the opposite side of the track.

Valves for Boiler and Steam Line Protection

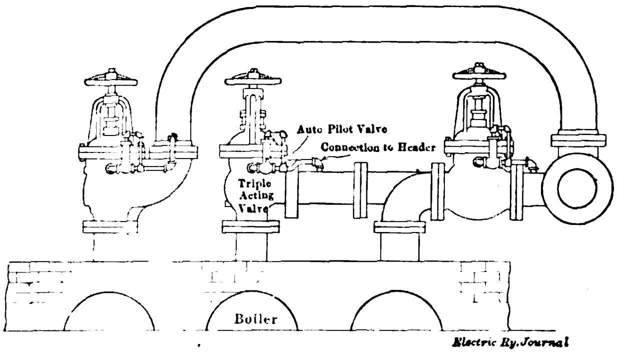
Of the valves made by the Golden-Anderson Company, Pittsburgh, Pa., the two hereinafter described are of special interest. One is a single-acting non-return valve for protecting the boilers only, the other is a triple-action valve for both steam line and boilers.

The single-acting valve is said to be the only non-return or automatic stop and check valve that can be tested in service. This valve is used in the connection from each boiler to the main steam line to prevent back flow from this line when the pressure in a boiler is lower or when it is cold. The valve embodies the Corliss dashpot method of cushioning, the full area of the upper portion of the body being occupied. Perfect alignment with the seat is also secured at all times regardless of position. The sectional views show the inside dashpot *A* attached to the valve spindle *D*, while the outside dashpot *B* acts as a bronze cylinder which is held firmly in place by the tap bolts. When the steam pressure raises the valve the resulting space between the inner and outer dashpots is instantly filled with steam, cushioning the valve in closing. The steam also circulates around and above the inside dashpot through the ports *C* and *E* to cushion the valve in opening. The small branch shown in the lower right-hand corner can be run to the floor or any other convenient point for testing the valve in service. Simply by opening the small valve the non-return valve will instantly close. By closing the small valve the non-return valve will immediately return to its automatic position. This feature enables the operators to determine at once whether the valve is operative, and avoids going on top of the boilers to close and open the non-return valve with the hand wheel. A solenoid and piping are also provided to permit remote control.

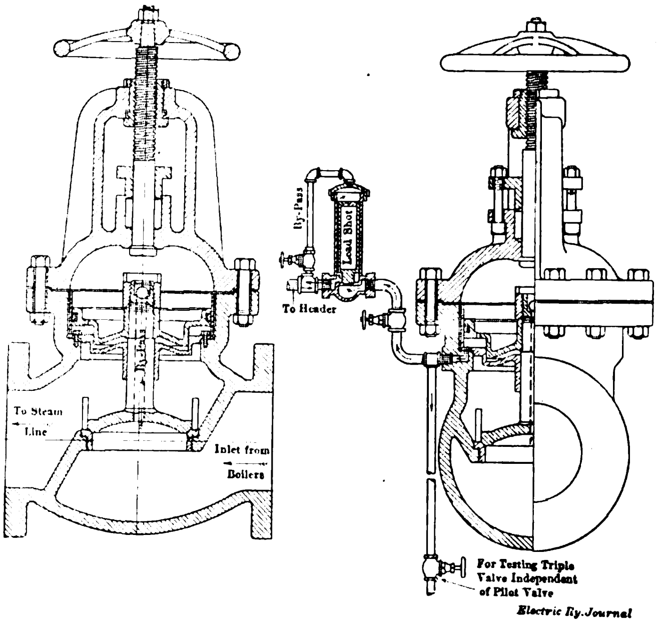


SECTIONS AND ELEVATIONS OF SINGLE-ACTING NON-RETURN VALVE

The triple-acting non-return valve requires only one connection to the header. As in the single-acting valve, the double Corliss dashpot is used to prevent sticking or hammering. Adjustment for any variation of pressure is made merely by removing the cap of the pilot valve and adding or removing lead shot or other weights from a hollow piston, as shown, for a greater or lesser variation between the boiler and header pressure. Valves of this type equalize the pressure between the different boilers, for they remain closed as long as the boiler pressure is lower than that of the header. When the pressure is equal they open automatically. The branch connection shown in the lower right-hand corner permits tests to be made from some convenient point as with the single-acting valve.



INSTALLATION OF TRIPLE-ACTING NON-RETURN VALVES



SECTIONS AND ELEVATIONS OF TRIPLE-ACTING NON-RETURN VALVE

News of Electric Railways

DECISION OF PITTSBURGH ARBITRATORS

An Abstract Is Presented of the Findings of the Majority, Adverse to the Men

The decision of the majority of the arbitrators in the wage dispute between the Pittsburgh (Pa.) Railways and its motormen and conductors, referred to briefly in the ELECTRIC RAILWAY JOURNAL of Nov. 7, page 1072, follows in part:

"We have reached the conclusion that the contention of the men for an increase over the present scale, or a change therefrom, should not be granted for Pittsburgh or for Washington, Pa.

"We will consider first certain claims for extra compensation not allowed by the present or former scales. At present no extra pay is allowed for night or holiday runs, for snow plow work, or for the five minutes a man is required to report before his platform work starts. Taking these up in order, it is contended by the employees that men operating night cars should be paid ten hours' pay for eight hours' work.

"Night work is an uncontrollable requirement of the public. As a general principle, the same reason which justifies extra pay for night work in time-controllable day ocupations, does not apply to street railway work. The absence of extra pay for night service, with the exception of one city, is the invariable practice of street railway companies.

"What has been said of night work applies to Sunday service. Conditions are unchangeable. On Sundays and holidays street traffic is not as heavy as on other days, there are fewer pedestrians on the streets and passengers are distributed more evenly over the entire day.

"The proofs in the case show that the men entitled to preference choose the Sunday runs and that in many instances where they take a rest day they take a week day in preference to Sunday. The general practice of American street railways is to allow no extra pay for Sunday work. In Pittsburgh the practice has been to allow in some instances ten hours' pay for eight hours' work on Sundays. The contention of the company is that this extra Sunday pay should be abolished; the contention of the men is that it should be further increased.

"The Pittsburgh Railways, however, has in the last schedule, and for some years, made some extra allowance for some Sunday runs. The reasons it now advocates for a change have always existed, and with them before it the company has chosen for some years to make this extra allowance. As we have said before, where any change in an existing scale is sought the burden of proof rests upon him who asks such change. We therefore adhere to the present scale.

"The conclusion has been reached that the agreement shall stand for two years from the date of this report and that the time blank in the agreement should be filled so as to read 'until Sept. 30, 1916.'"

The board made the following recommendations to the motormen, conductors and the company:

"First—That a board of co-operation be formed as follows: One man to be elected at each carhouse by secret ballot by the motormen and conductors in service more than six months. These twenty men, together with the general manager or superintendent of transportation and such other representatives as the company may select, not to exceed five persons, to constitute a board of co-operation. This board to meet at least once every month, to suggest and discuss methods of improving the service, of rendering it safer to the company, and in general to suggest ways and means of avoiding misunderstandings between the men and the company, and promoting good feeling on both sides. This board also to hear grievances and complaints that may be made by the men or the company and to suggest methods of reasonably meeting them. The election for the following period to be held at each carhouse once each year under the direction of the local committee of motormen and conductors and a local superintendent. The trainmen to be paid by the company at their regular rates of wages for all time employed by the men in attending the meetings.

"Second—That the subject of profit-sharing by the men in a percentage of the gross earnings of the company be jointly taken up by the motormen and conductors and the company, with a view to working out such plans."

EMPLOYERS LIABILITY INSURANCE IN CALIFORNIA

Financial Report Issued Indicating Success of the New State Department

The Industrial Accident Commission of California last December addressed the employers of the State, outlining the employer's liability under the workmen's compensation, insurance and safety act, and announcing that in establishing the State compensation insurance fund, the State had entered the insurance field to protect employers against their compensation liability. On Oct. 24, 1914, the manager of the compensation fund issued a financial report which is declared to be an indication of the success of the new State department. It is pointed out that as the State is not engaged in the insurance business for profit, the new department is the employer's own company, operated at a very low cost under State supervision, and providing service and protection of the highest class.

With the report appears a statement that, barring any unexpected calamity, those who hold State compensation insurance policies will be allowed a return premium of 5 to 25 per cent of premiums earned, the amount of return depending upon the experience in the various hazard groups. This return, however, will not affect minimum premiums. The California insurance laws require the setting aside of claim reserves equalling 72 per cent of all earned premiums, less losses and loss expenses paid, and this reserve must be maintained for five years. It is thought that there is no possibility of losses and loss expenses equalling that percentage, and that the difference between the reserve and the actual value of claims can ultimately be taken down. This would indicate a further return premium to 1914 policyholders, after a fair catastrophe surplus is set aside.

The initial insurance rates to be adopted for the coming year are the same as charged by the standard corporate companies, with the exception of the excess premium returns mentioned. All plants are inspected and the merit classification is applied to many. Where allowed, special merit inspections result in rate reductions of 1 to 40 per cent, the average reduction being 10.08 per cent.

The financial statement just issued covers the period from Jan. 1, 1914, to Oct. 1, 1914, during which time 5360 applications for insurance were received, and 2478 accident cases were handled. The expenses amount to 8.49 per cent of the premiums. The statement shows a total surplus of $224,020, of which $100,000 is the appropriation made last year and $124,020 represents accumulated surplus. The items that make up the totals are as follows:

Appropriation (1913 statute)	$100,000
Premiums written, less premiums returned	462,014
Interest received, due and accrued	4,502
Total	$567,017
Expenses and salaries	$41,328
Compensation and statutory medical payments	52,529
Outstanding cost, foregoing item	110,456
Unearned premiums	138,684
Total	$342,997
Surplus	$224,020

BOSTON TRANSPORTATION HEARING

Mr. Snow, for Boston Elevated Railway, Outlines Attitude of That Company Toward Proposed Unification

The Massachusetts Public Service Commission continued the hearing on Nov. 5 on the legislative resolve (Chap. 149, Acts of 1914) requiring the board to investigate transportation conditions in the Boston Metropolitan district. The proposed consolidation of the Bay State Street Railway and the Boston Elevated Railway was discussed by James F. Jackson, counsel for the former. The enabling act presented at the last Legislature was reviewed with special reference to its bearing on fare revision. It is expected that if the consolidation is approved by the Legislature a zone system of fares somewhat resembling that in use at Milwaukee will be submitted to the commission for approval. Frank B. Walker, civil engineer of the Bay State Street Railway, Boston, described various proposed track connections between the Boston & Maine, Boston & Albany and New York, New Haven & Hartford railroads and the Boston Elevated rapid transit lines, by which suburban trains may be run between the heart of the city of Boston and the outlying districts in establishing a comprehensive service in the metropolitan area. It was pointed out that this arrangement would relieve congestion at the existing railroad terminals, obviate the necessity of further costly extensions of elevated and subway structures and greatly improve the distribution of traffic. Chairman McLeod questioned the practicability of this part of the plan and pointed out that the rapid transit lines in Boston should be conserved to meet future demands upon them along existing channels of traffic instead of turned over to the accommodation of rolling stock diverted from the railroad lines of the metropolitan district.

For the Boston Elevated Railway, Frederic E. Snow pointed out the readiness of the company to enter into any comprehensive plan of consolidation or lease which will not add to existing unprofitable fare conditions. The company could not accept less than a 5-cent fare, but would be willing to extend this to Malden and Chelsea, which lie in general within the 4¼-mile radius of the Boston City Hall, which the joint commission on transportation estimated as the maximum profitable local ride for 5 cents. Residents of distant outlying suburbs cannot be carried to and from the heart of Boston at a 5-cent rate. The Revere Beach line of the Bay State Street Railway might be taken over under special excess fare arrangement. Mr. Snow said that in the event of a consolidation with the Bay State company a zone system of fares would be necessary and that the consent of the city of Boston would have to be secured to an alteration of the East Boston tunnel lease and to the transfer of the present subway leases to the new company. The Boston Elevated Railway did not desire to take on any new lines which would not be self-supporting and provide a return on the investment. Higher fares to and from the outlying districts are essential to a comprehensive development.

INJUNCTION GRANTED IN INDIANAPOLIS LABOR CASE

An injunction, *pendente lite*, enjoining officials of the Amalgamated Association and local labor union leaders from confederating to bring about a strike of the street railway employees at Indianapolis, and enjoining the car service men from striking, was issued on Nov. 7 by Judge A. B. Anderson of the United States District Court for Indiana. The injunction supersedes the temporary restraining order issued in September and continues effective until the decision on the final hearing for a permanent injunction. No date for the final hearing has been set by the court.

The individual service contract of the Indianapolis Traction & Terminal Company is found by the court to be valid, binding and effectual and in full force on its signers. The court finds that the defendants, William D. Mahon, Edward McMorrow, Joseph Colgan and R. L. Reeves, international officers of the Amalgamated Association, and the officers and attorneys for labor unions in Indianapolis, sustain no relations to the Indianapolis Traction & Terminal Company, but have confederated together to induce railway men who have not signed the individual contract and still work under the arbitration award contract to violate the provisions of the award contract by striking. The names of about 200 union men who are working under the award contract and more than 500 other men, practically all non-union, who are working under the company's individual service contract are included in the order of the court, and each is enjoined from striking or attempting to bring about a strike. The union officers previously mentioned are enjoined from combining and confederating or inducing or procuring any of the car men named in the order to violate the award contract or service contract by striking to compel the Indianapolis Traction & Terminal Company to operate upon the closed shop principle. The defendants are one and all enjoined from trespassing upon the property of the company or collecting in or upon the streets of Indianapolis or about the cars in such a manner as to interfere with the operation of cars or the employees. The order also enjoins all the defendants from interfering with any employee of the company in the discharge of his duties or by attempting to compel him to become a member of a labor organization by threats or intimidation.

MUNICIPAL RAILWAY CONSTRUCTION COST

According to a financial statement issued by the bookkeeping department of the Board of Public Works, the total cash available for construction work of the San Francisco (Cal.) Municipal Railways, when all of the sold bonds of the $3,500,000 issue voted on Aug. 26, 1913, are taken up, will be $2,666,159. The bonds to be sold total $857,500, giving a total estimated available amount from all sources of $3,523,659. Up to Sept. 26 there has been extended $1,915,567. There will be needed to complete work under way $718,227, and the engineers' estimate for new work amounts to $1,020,240, or a total of $3,654,034. The result is an estimated deficit to completion of $130,375. Some of the principal items included in the $1,915,567 of expenditures up to Sept. 26 are the following: Rails, $149,175; track specials, $118,653; car bodies, $144,650; car trucks, $36,250; motor equipment, $188,987; trolley poles, $61,237; Van Ness Avenue and Chestnut Street construction, $230,768; Potrero Avenue lines, $143,768; preliminary expenses—elections, $26,679, and Presidio & Ferries property, $312,535. The engineers' estimate for new work includes, among other items, the following: Track specials, $22,486; motor equipment, $15,348; plans and inspection, $54,000; California Street line, $127,500; Potrero carhouse, $211,345, and Church Street line (latest plans), $433,000.

During the year ended June 30, 1914, a total of 10.38 miles of track was added to the municipal railway system. The Van Ness Avenue line, 3.26 miles, was built primarily to serve exposition needs and was completed on Aug. 15. The Potrero Avenue line, 1.99 miles, running south of Market Street, was completed on Sept. 7. The Union Street line, 3.9 miles, was purchased from the Presidio & Ferries Railroad and put in service on Dec. 11. The Stockton Street line, 0.99 mile, completed this month, was built to connect Market Street with the Union Street line via the Stockton Street tunnel. The Masonic Avenue line, 0.26 mile, was built as a spur to the baseball grounds. Plans are now in course of preparation for three extensions; one on Columbus Avenue, one on California Street and a third on Church Street, the latter to cost about $330,000. The extension of the Geary Street carhouse is practically complete and the grading contract has been awarded for the 200-car shed on York Street.

MODIFIED CLEVELAND SUBWAY ORDINANCE INTRODUCED

At the regular meeting of the City Council of Cleveland, Ohio, on the evening of Nov. 9 Robert Koch, chairman of the committee on street railways, introduced an amended ordinance extending the time for starting the construction of the proposed subway, permitting larger tubes and increasing the price from $350,000 to $550,000 a mile of single track in the purchase clause. The measure was not discussed, but was referred to the Council committee of the whole. This ordinance permits stairways to stations to be 5 ft. wide, with entrances 6 ft. wide and 20 ft. long. Under it subway tracks may be brought to the surface to connect with surface tracks at locations approved by the director of public service. The ordinance further provides that the subways shall have a clear height of not less than 12 ft. and a clear width of not less than 10 ft. for each track. The construction of the first line is to be begun within twelve months from the time the ordinance goes into effect and be completed within thirty months thereafter. W. R. Hopkins, president of the Cleveland Rapid Transit Railway, stated that work may be begun sooner than stipulated, but that this depends on financial conditions.

Commissioner Hobbs reported on the cost of constructing a suspended railway of the German type. He thinks that such a road could be built at about $470,000 per mile of double track. His report showed the cost of elevated roads in New York and other cities.

The platform employees of the Cleveland Railway have decided to take their grievances to the City Council and ask that the company be authorized to make the expenditure necessary to grant a minimum work day of eight hours. Arbitration of the differences between the employees and company failed recently because certain points in the contract prevented action on the matters suggested by the men. George R. Davies, president of the local branch of the street railway men's union in Cleveland, stated on Nov. 9 that a committee will be appointed to work before the next session of the Legislature for a law fixing the number of hours that shall constitute a day's work.

NEW YORK TRANSIT MATTERS

Advertising Contract Disapproved and Relocation of Brooklyn Elevated Suggested

The Public Service Commission for the First District of New York has disapproved a contract, submitted on Feb. 2, 1914, which the Interborough Rapid Transit Company, lessee of the city subway, proposed to make with Artemus Ward for advertising, newsstand and vending machine privileges on that part of the dual system of rapid transit to be operated by the Interborough Company. The company had a contract covering such privileges in the old subway with Ward & Gow, which expired on Jan. 1, 1914, but contained a provision for a renewal for five years at a 10 per cent. increase. Before the expiration of the contract, however, the firm of Ward & Gow was dissolved and there was some question between the company and Artemus Ward as to his right as the successor of Ward & Gow to claim the right to a renewal. Therefore, the new contract was drafted and submitted to the commission. This contract was to cover a period of fifteen years from Jan. 1, 1914, and the contractor agreed to pay the Interborough Company $600,000 for that year, $700,000 each for the years 1915 to 1918, inclusive, and $800,000 for the year 1919 and each year thereafter, plus an additional sum equal to 10 per cent of the contractor's gross receipts. In disapproving the proposed contract, the commission adopted an opinion by Commissioner George V. S. Williams, in which he pointed out that the Interborough Company, as the lessee of the old subway, has the right to dispose of the advertising privileges therein without objection by the city until Jan. 1, 1917, when operation will be begun under the dual system contracts. These contracts cover the new subways as well as the old one, and provide for a division of profits between the company and the city. The city, therefore, is interested in any advertising contracts which may be made covering the period of dual system operation. The commissioner holds that the value of the advertising privileges will increase as time goes on and that better terms can be secured shortly prior to the beginning of dual system operation than can be obtained now. The dispute between the company and Artemus Ward as to the latter's right of renewal of the old contract for five years makes it impossible for the company to guarantee possession to a new contractor during such five-year period, and the commission was advised that because of this uncertainty it is impossible, at this time, to obtain effective competition for the privileges. Therefore, the contract was disapproved.

The New York Municipal Railway Corporation has applied to the Public Service Commission for a relocation of part of its Fulton Street elevated railroad in Brooklyn, in accordance with the plan favored by the committee on city plan and other citizens. This plan provides for the removal of the elevated structure from Fulton Street between Borough Hall and the Brooklyn Bridge and its transfer to Adams Street and private property. By an amendment to the rapid transit act, passed in 1913, the Public Service Commission is authorized, upon application from a company holding such a franchise, to relocate a line or part of a line in another street. Under the dual system contracts the company has the right to build a third track on the present elevated structure, and it is willing to apply to the cost of the new structure in Adams Street an amount equivalent to the money it would spend in erecting the third track. The company points out, however, that it is about ready to proceed with the third-tracking and urges immediate action if its application for a relocation in Adams Street is to be favorably considered by the commission and the Board of Estimate and Apportionment.

At the request of the financial officers of the city, the Public Service Commission for the First District has adopted a resolution asking that its engineering expenses since March 19, 1913, when the dual system contracts were signed, amounting to $3,533,000, be funded by the issuance of corporate stock instead of revenue bonds already issued in payment thereof and to be discharged by inclusion in the tax levy for 1915. The effect of this action will be to permit the city authorities to lower the tax levy for 1915 by the amount mentioned. The action is made possible by provisions of the dual system contracts, which authorize the charging of the commission's engineering expenses to the cost of construction of the new rapid transit lines.

DETROIT APPRAISAL FIGURES EXPECTED IN DECEMBER

It is unlikely that Prof. E. W. Bemis will present his appraisal of the property of the Detroit (Mich.) United Railway within the one-fare zone before Dec. 15, according to statements issued by the municipal street railway commission. The report was to have been received early in November, but various delays encountered indicate that no announcement of figures will be made until after the first week of next month.

Mayor Marx and a number of his heads of departments are making a tour to gather information as to surface railway service in several cities. Boston, New York, Philadelphia and other cities will be visited. It has been intimated by the anti-Detroit United Railway press rather than by the administration that upon the Mayor's return there will be some discussion with the company as to the service being furnished.

MONTREAL SUBURBAN LINE RECORD REVIEWED

The Montreal *Evening News* of Nov. 2 contained the following review of the activity of the Montreal & Southern Counties Railway, the property of which was described in the ELECTRIC RAILWAY JOURNAL of March 28, 1914:

"Sunday, Nov. 1, was the fifth anniversary of the opening of the Montreal & Southern Counties Railway. On Nov. 1, 1909, the first service between McGill Street and the South Shore was put in operation. The company then owned two passenger cars, and these made twenty-eight trips to and from St. Lambert only. To-day the company is operating more than 40 miles of track and is serving St. Lambert, Montreal South, Longueuil, Greenfield Park, Country Club, Chambly, Richelieu, Marieville, Rougemont and St. Cesaire, making in all ninety trips daily over the Victoria Bridge. In addition it has another 16 miles of track under construction to link up Abbotsford and Granby. In January next work will be begun on the extension of the tracks on the Montreal side as far as Youville Square.

"In place of the two cars which comprised the railway's rolling stock five years ago, there are now thirty-two passenger cars, two baggage cars, two flat cars, two rotary plows, one double track sweeper and one single track sweeper. During the first year 319,778 passengers were carried, while during the fiscal year ending June 30 last, W. B. Powell, the general manager, reports that the company carried 1,915,379 passengers.

"The effect which this line has had on the towns through which it passes is shown by the increased population figures:

	1909	1914
St. Lambert	1800	5300
Longueuil	3900	5800
Greenfield Park	500	1300
Montreal South	664	802

"In addition the company has been the means of opening up many new centers of population, including Alexandria Park, Rivera Park, St. Lambert Heights, St. Lambert Annex, Springfield Park, Sunlight City, East Greenfield Park, Pinehurst, Brooklin, Brentwood, South Kensington, Woodbine, Beverly, Albani, Belleville, Tunnel Terminals and Elswick Townsite."

ST. PAUL ELECTRIFICATION PLANS UNALTERED

C. A. Goodnow, vice-president of the Chicago, Milwaukee & Puget Sound Railway, has officially denied the rumor which has been prevalent during the past week to the effect that the voltage for the proposed electrification of a division of the railway would be raised to 6000. Mr. Goodnow stated that no change whatever from the originally planned voltage of 3000 is contemplated and that the work on the overhead construction which has been interrupted on account of a labor dispute will be continued in accordance with the scheme that was originally adopted, the design being exactly similar to the wooden pole and mast-arm, catenary arrangement that was installed on the Butte, Anaconda & Pacific Railway. Mr. Goodnow stated also that the order for the electric locomotives and substation equipment for the electrified division would be placed in the immediate future.

Progress on Philadelphia Electrification.—Steady progress is being made on the installation of tower footings for the overhead construction of the electrification on the Pennsylvania Railroad between Philadelphia and Paoli. The footings are completed nearly to the West Philadelphia station.

Bay State Arbitrators.—Henry E. Reynolds, assistant general manager of the Bay State Street Railway, Boston, Mass., has been selected to represent the company in the forthcoming wage arbitration proceedings. James H. Vahey, Watertown, Mass., has been named as representative of the employees. The third arbitrator will be selected by Messrs. Reynolds and Vahey.

Massachusetts Street Railway Association.—At the regular monthly meeting of the Massachusetts Street Railway Association, held at Young's Hotel, Boston, on Nov. 11, John A. O'Keefe, metropolitan fire commissioner, discussed the general problem of fire prevention in the Boston district, with particular reference to the organization of the State department of which he is the head.

Furthering Public Relations in San Francisco.—Jesse W. Lilienthal, president of the United Railroads, San Francisco, Cal., has recently sent out a letter to all the improvement clubs in San Francisco, announcing his consideration of the plan of a monthly letter which will deal with the future development work of the United Railroads and inviting suggestions for the improvement of conditions.

Mayor Marx, Detroit, Re-elected.—Mayor Marx was reelected in Detroit by a plurality approximating 20,000 over F. F. Ingram, who campaigned on a platform that charged the Mayor with the betrayal of the city's interest through the seven-for-a-quarter agreement with the Detroit United Railway in August, 1913. The supporters of the Mayor used as the principal slogan for his re-election "The man who took the street railway question out of politics."

Transportation Reviewed Before the Los Angeles A. S. M. E.—At a dinner given by the Los Angeles section of the American Society of Mechanical Engineers at Los Angeles, Cal., recently, Prof. George A. Damon, dean of engineering, Throop College of Technology, Pasadena, reviewed transportation development from the earliest times, illustrating his remarks with the stereopticon. He suggested for Los Angeles as the ideal a system of subways in the very densely settled section, with elevated lines in the less densely settled section and surface lines for the outlying sections.

Philadelphia Loan Bill Passed.—The bill releasing $11,300,000 for improvement work in Philadelphia, Pa., after Jan. 1 was passed at the recent election. Included in the items in the bill is an appropriation of $500,000 asked for by Director Taylor, of the Department of City Transit, and regarded by him as sufficient to complete the work of reconstructing and relocating sewers in the central portion of the city, where the subway loop will be located. The plans for this work were drawn by the department of surveys and are part of a comprehensive plan for a general reconstruction of the sewer system of Philadelphia.

Loyal Railway Purchase Negotiations.—Negotiations between the city of Seattle, Wash., and Harry Whitney Treat for the purchase of the Loyal Heights Electric Railway, which extends between the business district of Ballard and the Golden Gardens, have been tabled until after Jan. 1 1915. The city has decided that there is nothing to gain by proceeding with the negotiations until the bridge crossing the Lake Washington Canal at Ballard is completed, thereby insuring Division "A," of the Seattle Municipal Railway, entrance into Ballard. The Council contemplates purchasing the line as an adjunct to the other municipal lines.

Pacific Claim Agents' Index Bureau.—Although the extending of the services of the Pacific Claim Agents' Index Bureau to non-members was authorized last year, no steps were taken until recently to advertise this service. Now letters are being sent out to all lawyers and others who might have a use for the service, but who could not be expected to become members of the association. The minimum rate for service to non-members is $10. The bureau has discovered and exposed more than 200 accident repeaters in the last two years. The card-index cabinets of the bureau now contain more than 25,000 names of personal injury claimants assembled since the beginning of 1912, and it is estimated that the bureau has saved its members $500,000.

Agreement on Wages in Albany.—Employees of the United Traction Company, Albany, N. Y., have accepted an increase of 1 cent an hour in wages. The wage scale and other parts of the new agreement will be binding upon both parties until July 1, 1916. The men now are getting 27 cents an hour and under the settlement will receive 28 cents an hour from July 1 last. The company favored a sliding scale of from 24 cents to 29 cents an hour, depending upon the length of service. The officers of the company and the representatives of the men were at odds also regarding the length of the contract, the company's officials wanting the agreement to run for three years and the men for one year. Two years was finally agreed upon as a compromise.

Details of Cleveland Rapid Transit Mortgage.—The mortgage for $50,000,000 recently filed to the Central Trust Company, New York, N. Y., as trustee, by the Cleveland Rapid Transit Railway, as noted in the ELECTRIC RAILWAY JOURNAL of Nov. 7, is dated Oct. 9, 1914, and covers first mortgage bonds not exceeding the above amount and bearing interest at the rate not exceeding 6 per cent, issuable at $700,000 per single-track mile. The principal is due on Dec. 31, 1964, but subject to call on and after Jan. 1, 1916, at 103 and interest. The denomination of the bonds is $1,000. The proceeds are to be used for the construction and equipment, purchase or acquisition of subways, subway terminals, street railways and elevated railways for the conveyance of passengers and freight.

Financial Aid for San Francisco Employees.—Jesse W. Lilienthal, president of the United Railroads, San Francisco, Cal., has outlined the plans of the remedial loan association formed by the company to make loans to the employees. Employees who are in need of financial assistance are invited to write Mr. Lilienthal personally, stating the amount of money needed and the circumstances that caused them to run behind. It is planned to make up an estimate as to the amount of money that the company will have to maintain as a revolving fund to prevent the employees from doing business with the loan sharks. Such a fund will be available to employees at about 5 per cent, the idea being to fix the interest rate at a figure that will meet the expenses incident to administering the fund.

Clear Platform Rule Held Unlawful in Chicago.—Because of complaints of passengers and the liability of accident, the management of the Chicago (Ill.) Surface Lines endeavored recently to enforce strictly its rule prohibiting passengers from standing on the platforms when there was room in the car body. Some obstinate passengers refused to obey the conductors, and a conductor had three passengers arrested for not complying with his request to proceed into the car. Since there was no ordinance to support the rule and no law forbidding a passenger to ride on the back platform, the case was dismissed. L. A. Busby, president of the company, has explained that the rule was made to enable passengers to enter the cars with a minimum of discomfort to themselves and others and that the provision is in the interest of good service.

Electrolysis Hearing in Los Angeles.—At a hearing before members of the California State Railroad Commission, held in Los Angeles on Oct. 29 and 30, the Union Hollywood Water Company requested that the Pacific Electric Railway be required to make certain changes in its return system. The changes desired are: the installation of a system of return feeders or an equally efficient system; the placing of cross feeders to connect the return system with that of the Los Angeles Railway; the disconnection of negative substation busbars from all underground metallic structures excepting cable sheaths, and the installation of a set of wires for the purpose of connecting recording voltmeters to indicate the rail potentials. Experts for the water company and the railway presented data based upon tests including some made by the United States Bureau of Standards.

Meeting of National Civic Federation.—The national problems arising out of the war will be considered at the fifteenth annual meeting of the National Civic Federation to be held in New York City, Dec. 3, 4 and 5, 1914. The first day will be devoted to the woman's department, which will hold its sessions at the Colony Club, 120 Madison Avenue. The federation will convene at the Hotel Astor on Dec. 4 and 5. Among the subjects other than those arising out of the war which will be considered are governmental versus private enterprise, social welfare, workmen's compensation and unemployment. The federation has announced the establishment in the Metropolitan Tower, New York, of the permanent exhibit of typical welfare efforts for the enlightenment of employers about to install new features or to extend those already in force.

International Engineering Congress, 1915.—In view of the conditions now prevailing in Europe, the governing bodies of the five national societies under whose auspices the International Engineering Congress is to be held at San Francisco, Cal., Sept. 20 to 25, 1915, have recently given careful consideration to the feasibility of holding the congress and to the probability of its success, with the result that each body has unanimously confirmed its original pledge to support the congress. The committee of management is actively proceeding with arrangements for meetings on the scheduled dates and for the publications of the transactions. A detailed circular of information regarding the publications of the congress has been prepared by the committee and will be sent upon application to W. A. Cattell, secretary, in the Foxcroft Building, San Francisco, Cal.

Motor Carriages Wanted.—An American consular officer in East Africa reports that he has an inquiry for two or three railway motor carriages, which the government proposes purchasing through an agent in his district. The requirements are one closed carriage with a capacity of about fifty passengers, one open carriage with a capacity of from twenty-five to thirty passengers, and a closed inspection car. It is suggested that interested firms should send photographs or drawings and specifications giving export prices f. o. b. New York and c. i. f. destination. Time of delivery and terms of payment should be stated. Sufficient definite information to enable an order to be placed without further correspondence should be sent at once. The consular officer states that he would appreciate a duplicate set of pamphlets or catalogs on motor railway carriages. Further particulars may be obtained by addressing the bureau of foreign and domestic commerce, Department of Commerce, and referring to Inquiry No. 14,345.

Studying Difficult Extension of San Francisco Municipal Railway.—On Nov. 2 the Board of Supervisors of San Francisco passed a resolution calling for a progress report on the preparation of plans for the proposed Church Street extension of the municipal railway. The city engineer's office was ordered by the Supervisors on Sept. 14 to draw up these plans, the extension to cost about $200,000 and to include a means for handling the cars over the Church Street hill by a cable line. Replying to the request for a progress report, the city engineer stated that the auxiliary cable railway presents a number of problems which are new. The load that will be placed on the grip cars will be more than twice as great as the load at present on any grip car in San Francisco, and no grip design has yet been presented that the engineering department would approve. The sudden changes of grade render the design of satisfactory couplings difficult, and other problems have further complicated the work. The city engineer stated that plans and specifications will probably be ready about Dec. 1.

Extensions and Improvements in Los Angeles.—The total cost of street improvement work now on hand and proposed by the Pacific Electric Railway and Los Angeles Railway in Los Angeles, Cal., aggregates at least $1,110,000. Work in hand to be completed by the Pacific Electric Railway by June 1, 1915, amounts to $400,000, and in addition to this ordinances are running for the improvement of streets on which this company has lines aggregating 3 miles in length. This adds work that will cost about $250,000, according to the report. The Los Angeles Railway Corporation has under way or is about to start new construction on paved streets aggregating some $460,000. The Pacific Electric Railway recently called the attention of the civic authorities to the amount of work it has under way in the city, and asked permission to delay until next spring the paving to be done on certain streets. In his report, however, the city engineer pointed out that it would not be good policy to grant this extension of time because of the "piling up" of work and the resultant complaints that property owners would be sure to make.

Public Relations in Hot Springs.—The *New Era* of Hot Springs, Ark., recently contained an editorial in part as follows: "The Federal Light & Traction Company, owners of the public utilities companies in Hot Springs, is a corporation with a soul, and E. N. Sanderson, its president, is the heart of the soul. A corporation is an artificial being, invisible, intangible and existing only in contemplation of law. Therefore it cannot have a soul of itself. The soul must be furnished by the officials of the corporation. This is what has been done in the case of the Federal Light & Traction Company. Mr. Sanderson came here to see what the public utilities could do for the people. He has patiently listened to every suggestion and promised to do much for Hot Springs. We believe he is a man of his word and the company will do these things as soon as it can. Mr. Sanderson and W. A. Haller, general superintendent of the Federal Company, who is also here, should be extended every courtesy. Their company and S. E. Dillon, general manager of the public utilities, have the good-will of the people of Hot Springs and we believe they will voluntarily look after the best interests of its citizens."

Praise for the B. R. T.—The Brooklyn (N. Y.) Rapid Transit Company received a letter on Nov. 6 from Dr. Henry Ling Taylor, professor of orthopedic surgery of the Post-Graduate Hospital and secretary of the American Posture League, expressing the official approval of the league for the seat designed for the new subway car of the New York Municipal Railway Corporation through cooperation of the league's experts with the engineers of the railroad company. The official inspection by the members of the league, upon which this approval was based, was made on Nov. 5 at the Thirty-ninth Street shops of the railroad. Dr. Taylor in his letter said in part: "We wish to congratulate your company on its unusual consideration for the health and comfort of the traveling public, and especially on being the first railway that, to our knowledge, has sought scientific co-operation on this important question of providing a seat that shall support the body in correct posture. In particular we wish to express our appreciation of the skilful and courteous co-operation of your staff through a long period of mutual work that has put patience and effort to a severe test. The result is well worth the effort."

PROGRAM OF ASSOCIATION MEETING

New England Street Railway Club

The regular monthly meeting of the New England Street Railway Club will be held at the American House, Boston, Mass., on Nov. 19. Dinner will be served at 6 p. m. The speaker of the evening will be W. H. Tolman, Ph.D., director of the American Museum of Safety, New York. Dr. Tolman will speak on the subject, "Safety as Applied to Street Railway Work," and expects to embellish his talk with remarks on safety work in general. He will use the stereopticon to illustrate points which he desires to emphasize.

Financial and Corporate

RECENT FINANCIAL TENDENCY

The New York curb market was freed on Nov. 11 of all price restrictions by the committee which has been supervising dealings. On the same day the first open auction of securities was held since the Stock Exchange closed on July 30. The lifting of the ban on the curb market is expected to widen the market and have a general favorable effect on the whole security situation. In fact, the reopening of the exchange may be hastened by the developments in the unlisted share market. The dealings through the clearing house are said to be increasing, and the publication of the transactions is being urged as it is felt that such a course would be likely to stimulate the demand for stocks. Arrangements are reported to be proceeding smoothly for turning over to the Federal Reserve Bank on Nov. 16 the reserves which the member banks are called upon to set up with the central institution.

On Nov. 12 it was reported in Wall Street that a plan was under consideration to finance sound but technically insolvent houses by protecting their loans. It was also reported that the Clearing House bankers and the governors of the Stock Exchange were co-operating, with the idea of establishing a working basis for reopening at the earliest possible date, and that they were more hopeful than at any time in the past three months. On the same day there was a sharp decline in foreign exchange rates to the lowest level that has obtained since the war began. The fall in rates was on a very small volume of business. The low level of the day was 4.87, as against 4.89¼ at the close on Nov. 11. This compared with a quotation of 4.90¼ a week ago, and 4.96½ a month ago. Time money rates were lower and call loans were again made at 5½ per cent. The action of the committee of five on Nov. 11 in rescinding the rule which prevented transactions except as approved by it was followed on Nov. 13 by heavy buying of bonds and short-term notes and by activity and strength in unlisted securities.

OUTLOOK IN BIRMINGHAM

G. S. Orler & Company, Inc., Boston, in a recent circular letter recommended the deposit of the bonds of the Birmingham, Ensley & Bessemer Railroad with the bondholders' committee, headed by Charles H. Zehnder. The bankers also quoted from the report of Setchell & Luther, certified public accountants, Boston, who recently made an examination of the affairs and general working conditions of the railway.

The accountants made a special examination of the books and vouchers for the period ended Aug. 31, as well as a physical examination of the properties and a study of the franchises. They expressed their belief that the money expended in completing the road, for the purchase of equipment, etc., aggregating $1,801,891, had been judiciously handled and represents the valuation of the properties. The corporation is said to own valuable franchises and rights-of-way in Birmingham, and also a valuable charter which it acquired on taking over the Tidewater Railway, all of which cost $500,000 in bonds with a stock bonus. The revenue accounts indicate that with the completion of the Bessemer line and other contemplated extensions in Birmingham, a material increase will be evidenced in the gross receipts without a corresponding increase in operating expenses. This, it is believed, should result in a decided increase in net earnings and place the road on a paying basis.

According to the report presented to the U. S. District Court by I. W. Ross, receiver of the company, the revenues of the company for the twelve months ended Aug. 31 were $220,655. The operating expenses totaled $151,542, giving net earnings of $69,112. Against this amount there was charged $109,000 for interest on bonds, $5,499 for city license and $1,899 for the franchise tax, resulting in a deficit of $48,249. The directors of the company in a recent letter to security holders stated that the heavy cost of construction, much larger than the estimates, long hauls at low rates of fare, an interest charge of $196,000 during construction and unamortized bond discount of $376,000 had proved a burden which was too heavy for the company to carry.

ANNUAL REPORT

Third Avenue Railway

The consolidated statement of income, profit and loss of the Third Avenue Railway, New York, for the years ended June 30, 1913 and 1914, follows:

	1914	1913
Operating revenue:		
Revenue from transportation	$10,456,705	$9,742,345
Revenue from other operations	401,511	375,502
Total operating revenue	$10,858,216	$10,117,847
Operating expenses:		
Maintenance of way and structures	$1,012,646	$838,621
Maintenance of equipment	713,003	614,792
Depreciation	511,250	461,500
Power supply	779,131	794,484
Operation of cars	2,849,929	2,580,920
Injuries to persons and property	614,609	533,809
General and miscellaneous expenses	525,467	526,012
Total operating expenses	$7,006,035	$6,350,139
Net operating revenue	$3,852,181	$3,767,708
Taxes	730,784	725,693
Operating income	$3,121,397	$3,042,015
Interest revenue	75,215	70,170
Gross income	$3,196,612	$3,112,185
Deductions from gross income:		
*†Interest on funded debt	$2,368,072	$2,027,463
Interest on notes	134,174	107,236
Rent deductions, etc	38,060	30,528
Reserve for sinking fund	30,000	30,000
Total deductions	$2,570,306	$2,195,227
Net income	$626,306	$916,958

*Includes interest on adjustment income bonds at 5 per cent for the year 1914 and 3¾ per cent for the year 1913.

†Does not include interest on certificates of indebtedness of the Dry Dock, East Broadway & Battery Railroad.

NOTE—Operations of Belt Line Railway Corporation are included for the full year of 1914 and from March 22 to June 30, 1913.

During the year the revenue from transportation increased $714,360, or 7.3 per cent, and the total operating revenue increased $740,369, or 7.3 per cent. The increase of $655,896, or 10.3 per cent, in operating expenses was chiefly made up of an increase of $174,025, or 20.7 per cent, for maintenance of way and structure; $98,211, or 15 per cent, for maintenance of equipment; $49,750, or 10.6 per cent, for depreciation; $269,009, or 10.4 per cent, for operation of cars, and $80,881, or 15 per cent, for injuries to persons and property, with a deficit of $15,354, or 1.09 per cent, in power supply expenses. The net operating revenue increased $84,472, or 2.2 per cent, and owing to the fact that the slight increase in taxes was offset by an approximately equal increase in interest revenue, the gross income showed about the same increase in dollars as the net operating revenue. The interest on funded debt increased $340,609, or 16 per cent, which, with other slight increases in note interest and rent deductions, gave a total increase in deductions of $375,079, or 17 per cent. The net income decreased $290,652, or 31.6 per cent.

President Whitridge in his annual report states that the insurance rates on the buildings are less than one-half of what they formerly were. Cars are cleaned and carefully inspected each day, washed once a week with a carbolic solution and overhauled at the end of every 10,000 miles. The fund for depreciation, renewal and contingencies remained intact during the year. The payments into this fund amount to $500,000 per annum. The decrease in net income is accounted for by the fact that the company paid $281,000 for additional interest on adjustment bonds, and there were large expenditures for paving and other expenses caused by the heavy storms in February and March, to say nothing of the loss of receipts. Cash on hand amounts to $1,603,830, of which $746,883, together with 500 Third Avenue Railway first refunding mortgage 4 per cent bonds, is in the depreciation fund, $531,118 in the fund for the payment of interest and taxes and $325,829 in the current cash account.

President Whitridge says that it may be expected that a very large amount of money, more than enough to absorb all the net income, must be expended on the property during the year ending June 30, 1915, especially for pavements required by the city. He feels that it is a fair question whether under present conditions the railways should not be relieved from at least a part of the paving burden imposed upon them when their charters were obtained. He adds that the city does not protect railway tracks as it should from reckless use by trucks, automobiles and all sorts of heavy traffic.

Since the last annual report the Third Avenue Railway system has been increased by the acquisition of the Mid-Crosstown Railway, the Belt Line Railway and additional holdings in the New York City Interborough Railway, so that its total mileage is now 357.623. In February the Public Service Commission authorized the Third Avenue Railway to acquire $150,000 par value of the Mid-Crosstown Railway stock, and in April the company issued in payment with the consent of the commission $180,000 par value of its first refunding 4 per cent bonds and gave its promissory note for $250,000 and cancelled claims amounting to $34,442 against the Mid-Crosstown Railway. All the stocks and bonds of the Belt Line Railway Corporation were acquired by the Third Avenue Railway at a total cost of $2,723,044. The net earnings of the Belt Line company, after a payment of 5 per cent interest on the bonds, amounted to $23,885 for the year ended June 30. The Third Avenue Railway now owns $4,417,000 par value of the New York City Interborough Railway stock and $2,132,000 par value of its bonds. The aggregate cost of these securities and of certain unsecured debts to the Third Avenue Railway was $1,625,829. During the year the Third Avenue Railway cancelled $2,450,000 par value of the New York, Westchester & Connecticut Traction Company bonds and reduced this company's capital stock from $600,000 to $200,000.

During the six years of operation of the Third Avenue Railway Employees' Association the members and the company have each contributed $71,190. Sick benefits amounting to $39,187 have been paid to 3000 members and thirty-two death benefits of $250 were distributed. During the past year 725 cases received benefits amounting to $11,432, and $250 was granted to the beneficiaries in each one of ten deaths.

The engineers of the company have designed a new type of car with a seating capacity of forty-five as compared with fifty-one in the standard car, weighing 28,000 lb. as compared to the standard 38,000 lb. and using one-third less power than the standard. Fifty of these cars have been ordered and will be put in service during the coming year. It is hoped that they will be entirely paid for from the proceeds of the sales of old cars.

COLUMBUS REORGANIZATION PLAN CONTINUED

The boards of directors of the Columbus Railway, Power & Light Company and the Columbus Light, Heat & Power Company, both of Columbus, Ohio, have approved a plan outlined in a circular letter dated Oct. 24 to the stockholders of the latter company. It is stated that on June 17 there was presented a plan of reorganization and combination of interests of the Columbus Railway, the Columbus Railway, Power & Light Company and the Columbus Light, Heat & Power Company. The directors of the last-named company, believing that the plan would not give its stockholders the desired representation, opposed the plan.

The plan was subsequently modified, omitting the Columbus Light, Heat & Power Company, but the properties of the other companies were combined as contemplated, as described in the ELECTRIC RAILWAY JOURNAL of June 6, July 4, July 25 and Aug. 8. The Columbus Light, Heat & Power Company remained under lease to the Columbus Railway & Light Company, which had disposed of its contracts and assets to the Columbus Railway, Power & Light Company on Jan. 5, 1914.

Since the above developments negotiations were resumed, with the result that subject to the order of the Public Service Commission and the action of the stockholders of the two companies concerned, it has been agreed that under the new plan the holders of the $516,300 of preferred stock of the Columbus Light, Heat & Power Company are to receive preferred stock, series A, of the Columbus Railway, Power & Light Company, share for share, and the holders of the $210,500 of common stock are to receive preferred stock, series B, share for share, instead of the representation previously offered. It is recommended that this plan be accepted, and stockholders have been asked to deposit their stocks on or before Nov. 15 for exchange and authority to vote the same in favor of the carrying out of the suggested plan.

UNITED LIGHT & RAILWAYS CHART

The United Light & Railways Company, Grand Rapids, Mich., has compiled a chart showing the inter-corporate relations existing between the holding company and its subsidiaries as of June 30, 1914. On this date the United Light & Railways Company had outstanding in the hands of the public $7,713,600 of first preferred stock, $2,108,700 of 3 per cent second preferred stock, $6,898,700 of common stock, $7,214,000 of first and refunding 5 per cent bonds, $220,000 of 6 per cent notes due Jan. 1, 1915, and $500,000 of 6 per cent notes due Jan. 1, 1915, or a total capitalization of $24,655,000.

The company owns securities of subsidiary companies, exclusive of those of the Tri-City Railway & Light Company, to the amount of $958,400 of preferred stock, $7,855,751 of common stock and $1,286,000 of underlying bonds, a total of $10,100,151. The major part of this is deposited under the lien of the first and refunding bonds of the United Light & Railways Company. The Tri-City Railway & Light Company has outstanding $3,000,000 of preferred stock, $9,000,000 of common stock and $5,282,000 of first and refunding bonds, of which the United Light & Railway Company owns $173,800 of preferred stock, $8,823,500 of common stock and $2,076,000 of first and refunding bonds, or a total of $11,073,300. All of this is deposited under the lien of the United Light & Railways refunding bonds. The Tri-City Railway & Light Company has in addition to the above capital issued $7,889,000 of collateral trust bonds and $342,500 of assumed bonds of underlying companies, or a total capitalization of $25,513,500.

Excepting the Tri-City Railway & Light Company, the United Light & Railways Company owns all the outstanding securities of the subsidiary companies with the exception of $3,361,000 of bonds and $326,049 of stock. The Tri-City Railway & Light Company owns all the stock of its underlying companies, and all their outstanding bonds with the exception of $342,000. This ownership or control of substantially all stocks, both common and preferred, and a large part of the bonds puts the United Light & Railways Company in a strong position as regards the control over underlying companies.

American Railways, Philadelphia, Pa.—The American Railways has declared a quarterly dividend of 1¼ per cent out of earnings on the common stock, which is a reduction of one-quarter of 1 per cent from the usual quarterly dividend. The dividend is payable on Dec. 15 to stock of record Nov. 3. The following statement was issued by J. J. Sullivan, president of the company: "The reduced earnings for the past three months due to the general business depression made us feel that the wisest course to pursue under the circumstances was to curtail the dividend disbursement."

Boston (Mass.) Suburban Electric Companies.—A quarterly dividend of 50 cents a share has been declared on the 50,296 of preferred shares of the Boston Suburban Electric Companies, payable on Nov. 12 to holders of record on Nov. 5. This dividend compares with $1 per share paid quarterly from January, 1913, to July, 1914. It is stated that this reduction is expected to be only temporary, as the additional income of the Middlesex & Boston Street Railway, a subsidiary company, under the new schedule of rates just put into effect in accordance with the decision of the Massachusetts Public Service Commission as abstracted in the ELECTRIC RAILWAY JOURNAL of Nov. 7, page 1055, will probably be sufficient to enable the operating company to meet its interest and pay dividends. This in turn will enable the holding companies to meet the regular 4 per cent dividend requirements as in the past. The failure of the operating company to secure any additional revenues for the four months from July 1 to Nov. 1, during which time the need for additional revenue was acutely felt, made it seem advisable to pay but half the regular dividend at this time.

Chicago (Ill.) City Railway.—An old suit against the Chicago City Railway, originally brought up by Charles B. Venner in the State courts of Illinois, has been finally dismissed from the United States Supreme Court. The case was brought up to prevent the carrying out of the traction ordinance of Feb. 2, 1907, and the plaintiff suffered defeat in one state and federal court after another, the case finally going to the highest tribunal.

Columbus Railway & Light Company, Columbus, Ohio.—A dividend of 75 cents per share has been declared on the capital stock of the Columbus Railway & Light Company, payable on Nov. 20. No dividend will be paid to stockholders who are in default of payment on the assessment due on Dec. 30, 1913, or on June 30, 1914, but the dividend will be applied to the account of the assessment as of Nov. 20, 1914. This is the second disbursement to stockholders since the reorganization under the Columbus Railway, Power & Light Company, referred to more in detail in connection with this company elsewhere in this issue. As soon as all payments of assessments on the stock have been made, it is understood that the Columbus Railway & Light Company will be dissolved.

Detroit (Mich.) United Railway.—The first mortgage 5 per cent gold bonds, No. 101 to No. 150 inclusive, of the Detroit United Railway due on Dec. 1 are to be paid at par and interest at the Peoples State Bank at maturity. These bonds are part of an issue of $1,750,000 dated 1895, the first $600,000 of which matures $50,000 each year from Dec. 1, 1912. After the $600,000 of bonds is retired, a sinking fund will care for the payments of the remaining bonds in 1924. The payment of the bonds now called will make $150,000 of the issue retired.

Gary & Interurban Railway, Gary, Ind.—Application for an order dissolving the merger of four electric railways with the Gary & Interurban Railway, under that name, was denied by Judge Harry Tuthill in the Superior Court at Valparaiso, Ind., on Nov. 10, after he had had the evidence under consideration for seventy-five days. The application was made by minority stockholders, headed by Fred Raff, South Bend, representing 12,141 shares, par value of $25 each. The suit to dissolve the merger alleged fraud, but Judge Tuthill decided the merger was legal and that there was no attempt at fraud. The filing of the suit was referred to in the ELECTRIC RAILWAY JOURNAL of May 9, 1914.

Kansas City Railway & Light Company, Kansas City, Mo.—The committee representing the holders of the first lien refunding 5 per cent bonds of the Kansas City Railway & Light Company has arranged for payment at the New York Trust Company of the interest due on Nov. 15 on certificates of deposit as well as on the bonds.

London & Lake Erie Railway & Transportation Company, London, Ont.—A new mortgage to the Fidelity Trust Company, Ontario, dated Oct. 1, 1914, has been deposited in the office of the Secretary of State of Canada. This mortgage is the result of a recent vote by the stockholders authorizing an issue of mortgage bonds at $30,000 per mile upon the railway constructed and to be constructed.

Mahoning & Shenango Railway & Light Company, Youngstown, Ohio.—The application of the Mahoning & Shenango Railway & Light Company, the Wheatland Street Railway, the Valley Street Railway and the Sharon & Wheatland Street Railway for the approval of an agreement by which these companies are merged with the Mahoning & Shenango Railway & Light Company has been approved by the Public Service Commission of Pennsylvania. The merger is in accordance with the plan approved by the directors of the Mahoning & Shenango Railway & Light Company for unifying the corporate organization of the company, as referred to in detail in the ELECTRIC RAILWAY JOURNAL of Aug. 8, page 274.

New York (N. Y.) Railways.—Alexander J. Hemphill, Edwin S. Marston, Harry Bronner and Guy E. Tripp have issued a statement to the holders of the income bonds of the New York Railways defending the position of the directors of the company in its management of the property. The statement ends with the declaration that "if the bondholders prefer a less conservative course these directors will complacently leave it to others to assume the responsibility."

Northern Electric Railway, Chico, Cal.—Several meetings have been held by rival committees appointed by holders of underlying bonds of the Northern Electric Company and the junior bonds of the Northern Electric Railway. The indications are that the plan advanced by the Sloss interests for placing an issue of prior lien bonds ahead of the present outstanding first mortgage bonds will be rejected. Rudolph Spreckles, who represents $415,000 of the bonds, served formal notice on the Sloss trustees recently that foreclosure proceedings would be instituted if they did not guarantee the interest and the sinking fund of the bonds and maintain the priority of lien as provided in the trust deed.

Pacific Electric Railway, Los Angeles, Cal.—The Railroad Commission of California has issued an order extending to June 30, 1915, the effective date of a decision rendered April 8, 1913, in which the Pacific Electric Railway was authorized to issue $6,839,000 of refunding mortgage fifty-year gold bonds.

Philadelphia Company, Pittsburgh, Pa.—The Philadelphia Company has sent out the following notice to stockholders, signed by C. J. Braun, Jr., secretary: "In order to avoid inconvenience and expense, both to yourself and to the company, we have arranged to obtain funds from an outside source, with which to purchase its common stock dividend scrip issued on Nov. 2, 1914, to the holders of ten shares and under, provided the said scrip is rendered immediately."

Porto Rico Railways, Ltd., Toronto, Ont.—Concerning the recent passing of the quarterly dividend due on Oct. 1 by the Porto Rico Railways, as noted in the ELECTRIC RAILWAY JOURNAL of Oct 10, the directors in a recent circular said that they had found it necessary for the present to devote surplus earnings toward the liquidation of expenditures on capital accounts. During the spring and early summer Porto Rico passed through a severe business depression, caused partly by the abnormally low price of sugar and partly by the world-wide financial stringency, aggravated locally by protracted strikes in the tobacco industry. Conditions at the present, however, are steadily improving.

San Francisco (Cal.) Municipal Railway.—The Board of Supervisors of San Francisco on Oct. 26 ordered that $315,000 of municipal railway bonds be placed on sale in the office of the city treasurer. This amount was made up of bonds of $500 denomination, amounting to $210,000, and bonds of $100 denomination, totaling $105,000. The price fixed was par and accrued interest.

DIVIDENDS DECLARED

Boston (Mass.) Suburban Electric Companies, quarterly, 50 cents, preferred.

Central Arkansas Railway & Light Corporation, Hot Springs, Ark., quarterly, 1¾ per cent, preferred.

Columbus Railway & Light Company, Columbus, Ohio, 75 cents.

Pacific Gas & Electric Company, San Francisco, Cal., quarterly, 1½ per cent, original preferred; quarterly, 1½ per cent, first preferred.

Traffic and Transportation

CIVIL SERVICE EXAMINATION IN SAN FRANCISCO

Questions Used in the San Francisco Examination for Promotion from Motormen and Conductors to Inspector, Municipal Railways

As previously mentioned in the ELECTRIC RAILWAY JOURNAL an examination for promotion in the Municipal Railway Service, Department of Public Works, from the ranks of motormen and conductors to the rank of inspector, Municipal Railways, San Francisco, Cal., was held by the Civil Service Commission of that city on Oct. 31. The subjects of the examination and the relative weights of the subjects on a scale of 100 were: general knowledge of duties, 50; writing of reports, 25; arithmetic, 10; experience, 5; ascertained merit, 10. The subject "General Knowledge of Duties" included questions on the rules and regulations of the Municipal Railway Service, the location of the principal streets, parks, buildings and places of amusements in the city, the knowledge of transfer systems and time-tables, and questions relating to the general duties of motormen, conductors and inspectors, Municipal Railway Service. "Writing of Reports" was a test of the applicant's ability to write correct reports upon subjects to be named by the Civil Service Commission. "Arithmetic" embraced addition, subtraction, multiplication and division of whole numbers, and common and decimal fractions. Under the heading "Experience" applicants were awarded credits for experience had in street railway service in San Francisco as motormen, conductors or inspectors as follows: five years, 100 credits; four years, 75; three years, 50. Experience of less than three years and fractions of years between three and five years was not rated. Under the heading "Ascertained Merit" applicants with a clean record for the period they have been in the employ of the city as motormen or conductors were awarded the maximum credit, 100. Applicants guilty of neglect of duty, breach of discipline or other offenses were penalized as, in the judgment of the Civil Service Commission, was warranted. Only persons in the employ of the city as motormen or conductors on Sept. 28, 1914, were eligible as competitors. The questions which were asked and the credits allowed were as follows:

FIRST SUBJECT—"GENERAL KNOWLEDGE OF DUTIES."

Q. 1. Name four important duties of an inspector. 8 credits.

Q. 2. Name four important duties of a car dispatcher. 4 credits.

Q. 3. What are the rules regarding the issuance of transfers on the Geary Street line? 5 credits.

Q. 4. What are the rules regarding rights-of-way at the various crossings on the municipal lines on Van Ness Avenue and Potrero Avenue? 5 credits.

Q. 5. Name the streets in order as follows: (a) On the Geary Street line from Fillmore Street to Arguello Boulevard; (b) Presidio and Ferries line from Van Ness Avenue to the Presidio. 20 credits.

Q. 6. You are an inspector at Van Ness Avenue and a motorman of a car complains that his car acts badly and he does not know what is the matter. Name three points where you should first look for trouble. 6 credits.

Q. 7. While you are acting as inspector at Fillmore and Geary Streets, a trolley wire breaks at Geary and Steiner Streets. State what you did. 5 credits.

Q. 8. You are an inspector of the municipal railways detailed at the ferry. Travelers ask you for directions for reaching the places named below. Give best directions for reaching them by the street cars, preferring the municipal lines when they do not require the traveler to walk more than two blocks: Scottish Rite Auditorium; main entrance to exposition; Hamilton Square; temporary city hall; hall of justice; United States mint; United States custom house; Lane hospital; Southern Pacific Railway station; New city auditorium. State place at which you directed traveler to leave the car. 20 credits.

Q. 9. An inspector is required to turn in a daily report. Name seven subject titles under which the rules of the Municipal Railway require the matters covered by such reports to be classified. 7 credits.

Q. 10. Assume that the running time, with lay-overs, for round trip from the beach to the ferry is 99 minutes, equal time each way, and there are 22 cars to be operated on an even headway, the cars to be started at the beach, the first car leaving at 5:35 a. m. Make a schedule showing leaving time at beach and at ferry for first five runs up to about 10:50 a. m. 20 credits.

SECOND SUBJECT—"WRITING OF REPORT"*

You were detailed as an inspector on the Geary Street line at Van Ness Avenue. A fire occurs at Van Ness Avenue and Geary Street and several lines of hose are run across the tracks. In your judgment the blockade will last more than one hour. Cars are operating on a three-minute headway on Geary Street and on a six-minute headway on Van Ness Avenue. Fifteen minutes after this fire occurs you are notified that a car has been derailed in the crossover at Van Ness Avenue and Bay Street.

Write a report in not less than 100 words, addressed to the superintendent of the Municipal Railways, explaining the circumstances and telling what you did as an inspector. 100 credits.

THIRD SUBJECT—"ARITHMETIC"

Show all your work in full. No credit will be allowed for an answer without the work.

Q. 1. You are an inspector detailed for one hour at the receiving desk at the carhouse. Five cars turn in their cash with record of full fares received as follows: car No. 1, 625 fares; car No. 2, 783 fares; car No. 3, 596 fares; car No. 4, 759 fares; car No. 5, 847 fares. On counting the cash you find car No. 3 15 cents short. How much cash was received? 15 credits.

Q. 2. The cash receipts of one day's operation of the Geary Street line are $868.45. In addition transfers are received to the number of 6835. What is the total number of passengers of both classes carried during the day? 15 credits.

Q. 3. The municipal railway carried the following passengers in its first year:

Full fare passengers	8,882,996
Half fare passengers	49,035
Revenue transfer passengers	49,543
Non-revenue transfer passengers	631,363
Non-revenue passengers	110,240

What was the total number of passengers carried? 10 credits.

Q. 4. The total passenger car mileage for the first year of operation of the municipal road was 1,300,868.65 miles. What was the average number of miles traveled daily? (Carry out only to two decimal places.) 20 credits.

Q. 5. The city lines received transfer and cash fares as follows: 5280 transfers from the Kearny Street line; 3890 transfers from the Larkin Street line; 8520 transfers from the Divisadero Street line; 10,850 cash fares. The city received from the United Railroads 2 cents for each Kearny or Larkin Street transfer and 2½ cents for each Divisadero Street transfer. What was the total amount in cash received by the city for the cash fares and said transfers. 20 credits.

Q. 6. What is the total amount of a payroll consisting of the following items? 178 motormen, each 212 hours at 37½ cents an hour; 172 conductors, each 219 hours at 37½ cents an hour; 23 car repairers, each 244 hours at 42½ cents an hour; 11 trackmen, each 198 hours at 37½ cents an hour; 5 machinists, each 242 hours at 52 cents an hour. 20 credits.

---

*In this report make no personal references, and use only the address given you. Do not sign this report with your name, initials or address, or with any assumed name, initials or address. Any identification marks will exclude your entire examination papers.

REHEARING ASKED IN SOUTHERN PACIFIC RATE CASE

The Southern Pacific Company has applied to the Railroad Commission of California for a rehearing of the transbay rate case in which the commission refused to allow the company to raise its commutation rates between San Francisco and Oakland, Berkeley and Alameda, as noted in the ELECTRIC RAILWAY JOURNAL of Oct. 24, page 984. The application for rehearing is based upon the claim that the commission's refusal to allow the company to raise its rates is in violation of the constitution, in that it deprives the company of property without due process of law.

The company, in its application for rehearing, maintains that the commission has made no finding to show that the fair value of the railroad company's properties devoted to suburban service is less than $26,553,667; that while the commission held that the company's apportionment of its investment and expenses between main line and suburban service was erroneous, it failed to show wherein this apportionment was in error; that while the commission held that an increase in rates would confiscate or take away from the value of residence property in Alameda County, this was not a proper question for determination by the commission.

The commission has not yet taken any action in regard to the company's application, but has issued an order extending the effective date of its decision until the matter is finally determined.

Lexington Arbitration Board Complete.—Charles G. Bagby, an attorney of Danville, Ky., has consented to act as arbitrator between the union trainmen and the Kentucky Traction & Terminal Company over the alleged unwarranted discharge of a motorman recently.

Fare Increase Hearing Continued.—The Augusta-Aiken Railway & Electric Corporation, Augusta, Ga., has been authorized to file an amended petition in connection with its application to the Railroad Commission of South Carolina for permission to increase its fares and the hearings in the case will be continued.

Hearing on Rochester Fares.—At Rochester on Nov. 13 Commissioner Decker of the Public Service Commission of the Second District of New York was to hear the complaint of the city of Rochester against the New York State Railways as to fares during rush hours, routing of certain cars and the State Street carhouse.

Appeal in Middlesex & Boston Fare Case Probable.—It is expected that the municipal authorities of Waltham, Mass., will appeal from the Public Service Commission's decision granting 6-cent fares to the Middlesex & Boston Street Railway, by petitioning the Supreme Court of Massachusetts to set aside the finding of the board.

Experimental Cross Seat Car in Toronto.—The Toronto (Ont.) Railway is equipping one of its widest cars with a center aisle 21 in. wide and cross seats for the inspection of the members of the Ontario Railway & Municipal Board, which has before it an application from the union of street railway men in Toronto for an order to abolish the steps along the side of the open cars.

Incubus for Cleanliness on Passengers.—The Wichita Railroad & Light Company, Wichita, Kan., is seeking to arouse the public to recognition of the fact that their right to ride in clean cars is being violated by persons who expectorate on car floors or in window pockets. It is hoped by the company that under the pressure of adverse public sentiment these filthy practices will be discontinued.

Winnipeg Rerouting.—The routing of the cars on the Winnipeg (Man.) Electric Railway, which was rearranged by the City Council's traffic officer recently, is not generally approved and the matter has been taken up by the public utilities commissioner of Manitoba, who states that he will endeavor to arrange for the rerouting of the cars on the basis of the report presented early in the year by R. N. Feustel.

Prepayment Service at Providence.—Prepayment car service will shortly be inaugurated on the Elmwood Avenue lines of the Rhode Island Company at Providence. According to the company's franchise these cars cannot be operated on the prepayment plan until enough have been received from the manufacturers to equip the line on which they will be used. Upon the arrival of seven prepayment cars service will be begun on the Elmgrove-Reservoir line.

Date Set for Fare Hearing.—Dec. 2 has been fixed by the Railroad Commission of South Carolina as the date for the hearing on the application of the Charleston-Isle of Palms Traction Company, Charleston, S. C., for permission to increase the fare between Charleston and the Isle of Palms from 30 cents to 40 cents. It was erroneously stated in the ELECTRIC RAILWAY JOURNAL of Oct. 24, page 985, that the increase sought was from 25 cents to 40 cents.

Milwaukee Fare Zones Extended.—On Oct. 28 the Railroad Commission of Wisconsin handed down a decision extending the fare limits in two cases on the suburban lines of The Milwaukee Light, Heat & Traction Company. This change by the commission is generally regarded as in the nature of a concession in favor of the places affected by the increase in fares ordered on Jan. 2, 1914, and it involves no change by that body in the zone fare principle. The order was signed by two of the three commissioners. The company does not believe that the order coming six days before the election had any political significance.

Court Decision in Vermont Fair Case.—The Supreme Court of Vermont has handed down a decision in favor of the cities of Barre and Montpelier in their suits against the Barre & Montpelier Traction & Power Company in the matter of the proposed increase in street railway fares. The decision of the court, in short, holds that the franchise is a legal contract and that the railroad is obliged to maintain a fare not to exceed 5 cents within the respective limits of the cities in question and give transfers, so long as the franchise is in force. The *pro forma* degree is reversed and the cause is remanded with a mandate restraining an increase in fares.

Favorable Report on Springfield Service.—In a special report to the Board of Aldermen of Springfield, Mass., the committee on street railway service discusses the recent shortage of cars on the Springfield Street Railway, pointing out that the company will shortly place in service fifteen new pay-as-you-enter cars of Wason make, and stating that the unprecedented severe weather of the late winter disabled many cars in the early spring and handicapped the company's repair work. The report states that this caused congestion during the rush hours and made it difficult for the company to clean its rolling stock according to schedule. Up to Nov. 1, 1914, 171 cars had been overhauled, painted and varnished and 163 motors repaired and overhauled. Schedules have been revised, following consultations with R. W. Reynolds, general manager, and extra service provided in the rush hours.

Boston Transfers Approved.—The Massachusetts Public Service Commission has approved the establishment by the Boston Elevated Railway of free transfer privileges at Commonwealth Avenue and Essex Street in the Brighton district between Commonwealth Avenue and Cambridge surface cars. The board has approved the establishment of additional free transfer facilities at the Boylston Street subway stations, permitting passengers boarding cars on the surface at or west of the Church Street subway entrance to enter Copley Station and continue their trips westward in the subway, to leave the subway east-bound at Copley Station and continue their trips upon Boylston Street inbound surface cars, and to receive transfers to the Massachusetts subway station upon boarding west-bound surface cars after leaving Dartmouth Street. This extension of the transfer system will facilitate travel to and from the Back Bay shopping district, and minimize the effect of the new subway in the withdrawal of patronage from business houses on the surface.

Service Hearing in Toronto.—The Ontario Railway Board on Nov. 4 listened to the arguments of counsel for the city and the Toronto Railway in connection with the city's application for increased service. Corporation Counsel Geary reviewed the evidence of overcrowding and placed considerable emphasis upon the report of Charles R. Barnes, the board's expert, who recommended that a number of new cars be added; that cars be rerouted, and that crosstown lines be established. Mr. Geary insisted that the company could find capital for the extensions in spite of the war. H. S. Osler, counsel for the company, declared that it was unreasonable to expect the company to put 200 new cars in service and provide a seat for every passenger. He drew attention to the fact that Mr. Barnes had stated that had conditions at the time he made his investigation and report been the same as they are now he would not have recommended as he did. Mr. Osler felt that the board should recognize the fact that the company had succeeded in bringing the service to a point where little further need existed for improvement. At the conclusion of the hearing D. M. McIntyre, the chairman, intimated that the board would not delay its decision.

Personal Mention

Mr. R. R. Chestney has been appointed engineer of maintenance of way of the Macon Railway & Light Company, Macon, Ga., to succeed Mr. C. H. Fuller.

Mr. J. C. Boyd has been appointed engineer of the power station on the Galesburg & Kewannee Electric Railway, Kewannee, Ill., to succeed Mr. F. D. Marvin.

Mr. C. C. West has been appointed superintendent of traffic of the Galesburg Railway, Lighting & Power Company, Galesburg, Ill., to succeed Mr. Edward H. Nelson.

Mr. Ralph W. Purrington has been appointed superintendent of the Shelburne Falls & Colerain Street Railway, Shelburne Falls, Mass., to succeed Mr. Frank L. Reed.

Mr. Martin A. Brown, who has been auditor of the Shelburne Falls & Colerain Street Railway, Shelburne Falls, Mass., has been elected treasurer of the company to succeed Mr. Frank L. Reed.

Mr. L. A. Magraw, who has been chief engineer and electrical engineer of the Macon Railway & Light Company, Macon, Ga., has in addition been appointed general manager of the company, to succeed Mr. L. S. Boggs, resigned.

Mr. C. J. Davidson has been elected second vice-president of the Southern Illinois Railway & Power Company, Harrisburg, Ill., to succeed Mr. F. R. McMullin. Mr. Davidson also acts as chief engineer and electrical engineer of the company.

Mr. B. T. Longino, formerly superintendent of transportation of the Tacoma Railway & Power Company, Tacoma. Wash., is now assisting in the transportation department and "safety first" campaign of the Jacksonville (Fla.) Traction Company.

Mr. W. E. Boileau, formerly general manager of the Chattanooga Railway & Light Company and the Lookout Mountain Railway, Chattanooga, Tenn., has been appointed general manager of the Scranton (Pa.) Railway, to succeed the late Frank Caum.

Mr. G. W. Welsh has been appointed superintendent of power of the East St. Louis & Suburban Railway, with headquarters at East St. Louis, Ill. Mr. Welsh was formerly assistant electrical engineer of the Southern Pacific Company, San Francisco, Cal.

Mr. A. L. Kempster, manager of the Seattle division of the Puget Sound Traction, Light & Power Company, has been elected a life member of the Seattle Press Club. Nov. 19 has been fixed as the date on which Mr. Kempster will be presented with a silver life membership card.

Mr. J. Vipond Davies, vice-president of Jacobs & Davies, Inc., consulting engineers, New York, on Nov. 3 was awarded the Telford gold medal by the Institution of Civil Engineers, London, England, for his paper, "Extensions of the Hudson River Tunnels of the Hudson & Manhattan Railroad."

Mr. Elmer E. Bernard, assistant city engineer of Lynchburg, Va., has resigned and accepted a position with the Lynchburg Traction & Light Company and the Roanoke Railway & Electric Company, Roanoke, Va., as engineer of roadways. Mr. Bernard will make his headquarters in Lynchburg.

Mr. C. L. Daugherty, who has been electrical engineer of the Great Northern Railway, with offices in St. Paul, Minn., has been appointed assistant general manager of the St. Petersburg & Gulf Railway and the St. Petersburg Light & Power Company, St. Petersburg, Fla., a newly created position with the companies.

Mr. William B. McKinley, president of the Illinois Traction System, Peoria, Ill., who was elected congressman on Nov. 3 from the eighteenth Illinois district, expects to leave Jan. 1 for an extended trip around Cape Horn, going by way of the Panama Canal and down the west coast of South America and returning by way of Argentine Republic and Brazil.

Mr. Frank L. Reed has resigned as secretary, treasurer and superintendent of the Shelburne Falls & Colerain Street Railway, Shelburne Falls, Mass., but continues with the company as auditor and as a director. Mr. Reed will hereafter devote himself largely to the interests of the Monroe Bridge Paper Company, of which he has been elected treasurer and general manager.

Mr. Foster Hannaford, who has been assistant superintendent and operating engineer for the Galesburg Railway, Lighting & Power Company, Galesburg, Ill., has been appointed acting general superintendent to succeed Mr. D. McAffee. Mr. Hannaford has also been appointed acting general superintendent of the Peoples' Traction Company, Galesburg, to succeed Mr. McAffee.

Lieut.-Col. Chester Harding, corps of engineers, U. S. Army, has severed his connections with the District of Columbia to accept the detail as engineer of maintenance of the Panama Canal. He has been succeeded as a member of the Public Utilities Commission of the District of Columbia by Maj. Charles W. Kutz, corps of engineers, U. S. Army, who has been elected chairman of the commission to fill the unexpired term of Colonel Harding.

Mr. W. C. Myers has been appointed assistant general superintendent of the East St. Louis & Suburban Railway, with headquarters in East St. Louis, Ill. In 1910 Mr. Myers was appointed superintendent of electric shops and equipment with jurisdiction over electric car inspections and maintenance during construction and operating periods on the Oakland, Alameda and Berkely line of the Southern Pacific Company, which was then being equipped with electricity. Before that Mr. Myers was with the General Electric Company.

Mr. Charles F. Hewitt, who was recently appointed general manager of the United Traction Company, Albany, N. Y., was tendered a complimentary dinner at the Claridge Hotel, New York, on the evening of Nov. 6. The committee in charge of the dinner consisted of Mr. H. N. Ransom, Mr. E. S. Fassett, Mr. C. C. Castle and Mr. H. C. Evans. Fifteen or more of the two score present, including Mr. C. Loomis Allen, president of the American Electric Railway Association, and Mr. C. S. Sims, vice-president of the Delaware & Hudson Company, expressed briefly their appreciation of Mr. Hewitt's past work and referred to the problems which he will be called upon to face in Albany. They extended a hearty welcome to him and offered him the results of the experience of the electric railway men of the State of New York. In response, Mr. Hewitt outlined briefly his early experience in electric railway work in Elmira, Syracuse and elsewhere and stated that with the co-operation which was assured he felt that he was starting his new work under auspicious conditions.

Mr. Peter E. Hurley has been appointed general manager of the Trenton & Mercer County Traction Corporation, Trenton, N. J., to succeed Mr. William H. Hitchcock, resigned. Mr. Hurley resigned as general manager of the corporation on Jan. 1, 1911, and since then has been engaged principally in the contracting business. He had previously served the Trenton Street Railway. Mr. Hurley is fifty years old. He was born in Monmouth County, N. J., where he worked on his father's farm until he decided to locate in Trenton. His first job in that city was as driver of a stage, on what was known as Wayman's Line, carrying passengers between the city hall in Trenton and Riverview Cemetery. He next got a position as driver on the horse car line operating between the Clinton Street Station and Prospect Street, Trenton, at that time the only line of its kind in the city. When the Center Street division was built Mr. Hurley, after having received several promotions, became superintendent and later was advanced to general manager. After serving several months with the new company he resigned to enter other business.

Mr. W. H. Glenn, who has been vice-president and manager of railways of the Georgia Railway & Power Company, Atlanta, Ga., has surrendered that title for vice-president and operating manager, with widely increased duties which include not only the management of the railways but supervision over generating stations, transmission lines and the distribution system. Mr. Glenn was manager of railways for the Georgia Railway & Electric Company when the property of that company was leased to the Georgia Railway & Power Company. He became connected with the engineering department of one of the constituent companies of the Georgia Railway & Electric Company after he was graduated from the Georgia School of Technology. Subsequently he served for several years in the shops. He next served as purchasing agent of the company. Later he was appointed superintendent of track and roadway, and in that capacity he had charge of most of the reconstruction work which followed the formation of the Georgia Railway & Electric Company and worked out many of the problems incident to the changes in the physical property which followed the consolidation. Mr. Glenn was appointed general manager of the railway department of the Georgia Railway & Electric Company in January, 1908.

Mr. W. H. McGrath, who succeeded Mr. A. W. Leonard on Nov. 1 as manager of the Puget Sound Traction, Light & Power Company, Seattle, Wash., and subsidiary companies on the election of the latter to the position of president, has been connected with public service properties for the last fourteen years. After graduating from Harvard in 1901 with an engineering degree, Mr. McGrath went with Stone & Webster and gained experience in every department of the Boston office work. In 1902 he was appointed electrical engineer for the company at Houghton, Mich., and became superintendent of the Houghton County Electric Light Company about 1903. In 1905 Mr. McGrath was made manager of Houghton County Traction Company and Houghton County Electric Light Company, both Stone & Webster properties. He served in this position until 1909, when he was transferred to Minneapolis as assistant to Mr. A. W. Leonard, at that time vice-president and manager of the Minneapolis General Electric Company. During some of the trying times of this company and until 1912, when Stone & Webster sold the property, which then was very successful, he held the position of assistant general manager at Minneapolis. In June, 1912, Mr. McGrath returned to Boston and took up expert work for Stone & Webster in connection with the examination, analysis and organization of new properties and for other interests, bankers, etc. In November, 1913, he was appointed assistant to the vice-president of the Puget Sound Traction, Light & Power Company, Seattle, which position he held until Mr. Leonard's election to the office of president.

OBITUARY

John Kean, formerly Senator from New Jersey, is dead. Mr. Kean was born on Dec. 4, 1852. He was educated at Yale and at the Columbia Law School, and was admitted to the New Jersey bar in 1877. Mr. Kean never practiced law, but turned his attention to banking and manufacturing. He was at different times a director of the Manhattan Trust Company, Chicago Junction Railways, Union Stock Yards Company, Twin City Rapid Transit Company and the North Hudson County Railway, which is now included in the system of the Public Service Corporation of New Jersey.

J. N. Akarman, of the Akarman Company, engineers and contractors, Atlantic City, N. J., is dead. Mr. Akarman was born on March 4, 1854. He began his railroad career in 1873 with the South Boston Railroad. In 1887 he became one of the subordinate officials of the Middlesex Railroad running between Boston and Charlestown, Mass. Six years later he became superintendent of the Charles River Street Railway. When the Charles River Street Railway was consolidated with the Cambridge Railroad, Mr. Akarman resigned to become general superintendent of the railways in Worcester, Mass., owned by the Seeleys. He next assisted in building the Biddeford & Saco Railroad between Biddeford and Old Orchard Beach, Maine. After the completion of this road he accepted the position of general superintendent of the railways in Newark and Elizabeth, now included in the system of the Public Service Corporation of New Jersey. In 1892 he returned to Worcester as general manager of the Worcester Consolidated Street Railway, in which capacity he continued until 1901, when he was appointed general manager of the Elizabeth, Plainfield & Central Jersey Railway. When the last mentioned property was absorbed by the Public Service Corporation he entered the service of that company, filling while with it the positions of traffic superintendent, general passenger agent and general superintendent of the South Jersey division.

Construction News

Construction News Notes are classified under each heading alphabetically by States.

An asterisk (*) indicates a project not previously reported.

RECENT INCORPORATIONS

***Edmonton Northwestern Radial Railway, Edmonton, Alta.**—Application for a charter has been made by this company to the Alberta Legislature in Alberta to build an interurban railway, to be operated by any other power than steam, from Edmonton northwesterly to the Pembina River. Short, Woods, Biggar & Collison, Edmonton, Alta., are the solicitors for the applicants.

FRANCHISES

Los Angeles, Cal.—The Pacific Electric Railway has asked the Council for a three months' extension of time on its franchise in which to build a second track on New Magnolia Avenue. It is expected that this company will soon ask for a franchise on Market Street. Bids will soon be awarded by the company for the construction of the extension to Corona.

Los Angeles, Cal.—The Southern Pacific Company has received a franchise from the Council to extend its tracks over certain streets in Los Angeles.

Los Angeles, Cal.—In response to the appeal of the Glen Alto Improvement Association the public utilities committee of the Council of Los Angeles has recommended the granting of a franchise for an electric railway extension from North Broadway and Prichard Street through Schuetzen Park and the Hermon districts to the boundary limits of South Pasadena. The committee recommends that the Council offer the franchise for sale at once. [E. R. J., Oct. 24, '14.]

Sausalito, Cal.—Allen H. Vance has been authorized by the Railroad Commission to transfer to the Sausalito Incline Street Railway a franchise authorizing the construction of an incline railway over certain streets and private rights-of-way in Sausalito, and the latter company granted a certificate of public convenience and necessity to exercise rights thereunder. The company has been authorized to issue its preferred stock of the par value of $2,500 to Allen H. Vance and preferred or common stock of the par value of $15,500 to be sold at par for cash only, $500 of the proceeds thereof to be used in preparing plans of the proposed incline railway, the balance for securing rights-of-way and terminal grounds. [E. R. J., Oct. 17, '14.]

Atlanta, Ga.—No further extension of time will be granted the Atlanta & Carolina Railroad to begin work on its proposed electric railway between Atlanta and Augusta. The electric railway committee of Council recently refused the request of the company that additional time be granted. The line was projected in 1907. Little actual construction work has been done.

Carbondale, Ill.—Plans are being made to soon ask the Council for a franchise to build an electric line in Carbondale. This is part of a plan to build a 12-mile interurban line between Carbondale and Murphysboro, Ill.

New Bedford, Mass.—The Union Street Railway has received a franchise from the Council to extend its lines over certain streets in New Bedford.

Pittsfield, Mass.—The Berkshire Street Railway has asked the Massachusetts Public Service Commission for an extension of time in which to finish the construction and alterations of its lines in North Street and Wahconah Street in Pittsfield.

Brantford, Ont.—The Brantford & Hamilton Electric Railway has asked the Canadian Parliament to extend the time within which the company may begin and complete the line authorized to be built from Langford to Galt.

Montreal, Ont.—Mayor Martin proposes that the Council of Montreal shall give the Montreal Tramways Company an extension of franchise for twenty-two years, on condition that the new franchise shall cover all the existing franchises with the various sections of the city which have been annexed since the original franchise was granted. These are numerous, and some of them are for fifty years or more, while one is in perpetuity. The main franchise has eight years to run, so the extension advised by the Mayor is practically for thirty years. The company asked for a forty-year extension. The question will be considered by the Board of Control at an early date.

Toronto, Ont.—A motion of Comptroller Church that the Works Commission report on the extension of the civic lines in Toronto to North Toronto, Beaches, Ward Seven and Rosedale was carried by the comptrollers on Oct. 27.

Three Rivers, Que.—The Three Rivers Traction Company has asked the Council for a franchise in Three Rivers.

Knoxville, Tenn.—The Knoxville Railway & Light Company has accepted a franchise from the Council for an extension of its lines in Knoxville. The ties for the extension are already on hand and special steel work has been ordered.

Nashville, Tenn.—The Nashville Traction Company has asked the Council for a franchise to extend its lines out Fifth Avenue to the north. The measure supplements an ordinance which gives the company privilege to extend its lines in North Nashville.

Richmond, Va.—The Virginia Railway & Power Company has asked the Council for a thirty-year franchise to extend its lines in Richmond.

TRACK AND ROADWAY

Burlingame (Cal.) Railroad.—Work has been begun by this company surveying for the extension along the present route of storage-battery road from the station in Easton to Burlingame Hills.

San Francisco (Cal.) Municipal Railway.—A branch to begin at Van Ness Avenue and Market Street and extend to Duboce Street, Castro Street, Fourteenth Street and Alpine Street to be constructed out of the $3,500,000 bond issue, and its future extension across Buena Vista Hill into the Pope tract, is advocated by the Fifteenth Street and Park Hill Improvement Association in San Francisco.

Jacksonville (Fla.) Traction Company.—Plans are being made by this company to extend its lines in Jacksonville.

Miami (Fla.) Traction Company.—Work has been begun by this company laying track on its line in Miami. Excavation at the bridge will be begun at once and the work carried westward. B. B. Tatum, Miami, president. [E. R. J., Oct. 31, '14.]

Jacksonville & St. Augustine Public Service Corporation, St. Augustine, Fla.—This company has completed 6 miles of the interurban railway between Jacksonville and St. Augustine and will soon place it in operation. This 40-mile line will connect Jacksonville, South Jacksonville and St. Augustine. J. L. Crary, St. Augustine, is interested. [E. R. J., June 20, '14.]

East St. Louis & Suburban Railway, East St. Louis, Ill.—New tracks will be laid by this company on Main Street in East St. Louis in the spring, when its new office building, which fronts on Main Street and Collinsville Avenue, will be completed. The offices of the company will be removed from Third Street and Broadway to the new building.

Freeport Railway & Light Company, Freeport, Ill.—This company is ready to submit to the Council committee on electric railways the choice of three routes for the proposed extension of this railway in the southwest section of Freeport.

Illinois Traction System, Peoria, Ill.—The extension of the company's line from Twelfth Street station south through St. Louis over the free bridge, to Belleville by way of the Southern Traction Company's line and then to Edwardsville will follow the completion of the east approach of the bridge. The plan also contemplates an elevated structure from the Illinois end of the McKinley Bridge above Main Street in Venice and then along a privately owned right-of-way above Granville Street above the Terminal tracks at the north end of the Madison yard. This company has completed a new bridge at Mackinaw. The structure is built with concrete abutments and ballast decks and has an 80-ft. span. The cost of the new bridge was $25,000.

Springfield & Central Illinois Traction Company, Springfield, Ill.—It is said that plans are being made to secure the renewals of all the franchises and other rights of this company which expire on Jan. 1, 1915, the originals having been granted for a period of two years. At a meeting of the stockholders held recently at East St. Louis the following officers were elected: Isaac Smith, president; George W. White, vice-president, and A. C. Skilman, secretary. The same directors were re-elected. [E. R. J., July 19, '13.]

Aurora, Elgin & Chicago Railway, Wheaton, Ill.—This company is asked to consider plans to build a loop line through the southeastern section of Elgin.

Wabash & Rochester Electric Railway, Wabash, Ind.—No definite plans have been decided upon by this company as to when construction will be resumed on this proposed line to connect Columbia Park, Rochester and Lake Manato.

Louisville (Ky.) Railway.—This company is asked to consider plans to extend its Walnut Street line, which ends in Parkland, out Catalpa Street and to Southern Avenue, thence to the State Fair Grounds.

***Paris, Ky.**—Business men in this section of the State are discussing a proposition to organize a company to promote an electric interurban railway to extend from Paris to Carlisle and thence to Maysville. The Louisville & Nashville Railroad recently discontinued a number of passenger trains on its Maysville branch.

***Mattawamkeag & Northern Railway, Bangor, Maine.**—Interest has been revived in the plans to build a 4-mile line from the junction of the Medway and Houlton roads in Mattawamkeag and extending along the Medway road toward Medway and Molunkas as far as Mattaceunk Rips in the Penobscot River, where an extensive power development is proposed. The railway as originally planned was to extend from Mattawamkeag through Molunkas, Medway, East Millinocket to Millinocket, 22 miles. Charles W. Mullen, Bangor, is interested.

Quebec Extension Railway, Presque Isle, Maine.—Preliminary arrangements are being made by this company to begin work in the spring on this proposed electric and steam railway to connect Quebec, Charlesbourg, Lorette, Ste. Foye, Valcartier Military Camp, Cap Rouge and Beauport. The electric power can be secured from the Shawinigan Company, the Dorchester Electric Company or the Quebec Railway, Light, Heat & Power Company. Plans are being made to secure a subsidy of $6,000 per mile for the construction of the railway, from the federal government of Canada. The company is open for tenders for the construction of this line. Alleyn Taschereau, Quebec, solicitor. [E. R. J., Oct. 12, '14.]

Detroit (Mich.) United Railway.—This company has placed in operation its new Grand Belt division between Fort Street and Clark Avenue and Thirty-fourth Street and Warren Avenue in Detroit.

St. Paul (Minn.) Street Railway.—This company has placed in operation its new Western and South Robert Street line in St. Paul.

St. Paul Southern Electric Railway, St. Paul, Minn.—This company has completed and will soon place in operation the first section of its line between Hastings, Neb., and St. Paul, Minn. The line will enter the city of St. Paul over the tracks of the St. Paul City Railway. This line will eventually be extended to connect Cannon Falls, Red Wing, Frontenac, Lake City, Mankato, Inver Grove and Faribault.

Battle Creek, Coldwater & Southern Railway, Battle Creek, Mich.—As soon as financial backing can be secured work will be begun by this company on the line between Battle Creek, Coldwater and Girard. The following officers have been elected: T. A. Hilton, president; J. F. Thompkins, Girard, vice-president; E. F. Pangburne, secretary, and A. J. Dorrance, Coldwater, treasurer.

Missoula (Mont.) Street Railway.—This company has been asked to extend its East Side line to the upper end of Parkside Addition, in Missoula, on the Rattlesnake Creek, a distance of about 1 mile. The company has intimated that the line will be built in the immediate future.

Brooklyn, N. Y.—Bids are desired until Dec. 1 by Public Service Commission, First District, 154 Nassau Street, New

York, N. Y., for reconstruction of part of Section No. 9-C-1 of Route No. 9, a part of the Fourth Avenue subway in Brooklyn, which includes the installation of cross-overs and the partial reconstruction of the DeKalb Avenue station in Flatbush Avenue extension.

New York State Railways, Rochester, N. Y.—Work has been begun by this company relaying its tracks and placing new ties on certain sections of Park Avenue in Rochester. This is done in connection with resurfacing the street by the city. The company will also pave its part of the street.

Cleveland (Ohio) Railway.—This company is asked to consider plans for an extension through West Madison Avenue in Cleveland.

Cleveland, Alliance & Mahoning Valley Railroad, Cleveland, Ohio.—Surveys have been made, grading completed, poles set and plans are being made to soon begin the overhead work on this 7-mile line from Newton Falls to Leavittsburg. All material has been bought. C. R. Morley, 756 Hippodrome Avenue, Cleveland, president.

Bartlesville (Okla.) Interurban Railway.—A contract has been awarded by this company for the laying of concrete on the right-of-way of this railway on Wyandotte Avenue between Seventh Street and Fourth Street in Bartlesville. This is in anticipation of the paving which is to be begun at once.

Ontario West Shore Railway, Goodrich, Ont.—Negotiations have been opened by Contractor Campbell, of Strathroy, Ont., with the municipal authorities interested in this incompleted railway, with a view of something being done towards its completion. The contractor has agreed to submit a proposition to the municipalities to complete the grading and to do the tracklaying. [E. R. J., May 16, '14.]

Dunnville, Wellandport & Beamsville Electric Railway, Wellandport, Ont.—This company has secured deeds for a considerable stretch of private right-of-way. About 12 miles of grading has been done. The Hydro-Electric Power Commission of Ontario has been going over the route from Dunnville to St. Catherines, in order to prepare a report, there being a proposition that the line be taken over and completed as part of the commission's proposed system of interurban lines. J. A. Ross, Wellandport, president.

Toronto, Ont.—On Oct. 24 the Ontario Railway Board, acting upon an application made by the city, gave formal approval to the construction of a civic car line along Bloor Street from Dundas to Quebec Avenue in Toronto. All that remains to be done is to secure from W. H. Hearst a formal assurance that when the House meets next session legislation will be put through validating the by-law the city proposes to pass to raise the money (some $150,000) to build the line. It is said that Works Commissioner Harris is already getting ready for construction. If delays are avoided it is expected the line will be ready for service next Spring.

Metolius, Prineville & Eastern Railway, Prineville, Ore.—This company states that surveys have been completed, right-of-way secured, but no definite plans have yet been decided upon in regard to the construction of the 30-mile line to connect Metolius and Prineville. H. B. Scheel, Prineville, president. [E. R. J., April 25, '14.]

Seaside, Ore.—Preliminary steps have been taken to build an electric interurban line from Seaside to Astoria as the first link in a comprehensive coast system of electric lines. The City Council was asked to extend the time limit on a franchise through Seaside that is held now by O. W. Taylor. Prior to the presenting of the request to the Council, considerable work had been done by interested residents of Seaside and Astoria in securing data, and it is believed that practically all the necessary right-of-way can be had gratis and that at least part of the cost of the line can be secured in the immediate vicinity.

Philadelphia (Pa.) Rapid Transit Company.—Plans are being made by this company to begin work in the spring on a new double-track crosstown line on Fifty-sixth Street in West Philadelphia.

Pittsburgh, Harmony, Butler & New Castle Railway, Pittsburgh, Pa.—Plans are being considered by this company for a line between Rochester and Beaver Falls.

Pittsburgh, Pa.—The Chamber of Commerce will propose to the City Council at the next meeting that it solve the subway question by the construction of a downtown loop and lease it to the Pittsburgh Railways Company. The plans have been worked out by the board of directors and will come before the Chamber of Commerce for final approval at a meeting to be held within the next few days.

***El Paso, Tex.**—A company is being organized to build an electric railway from the center of El Paso through the suburbs to Woodlawn addition, east of El Paso. A right-of-way on Tenth Street will soon be asked for. Thomas P. Ruddy, Kansas City, and other Kansas City capitalists are interested.

Houston (Tex.) Electric Railway.—This company will soon double-track its lines on Fannin Street and on Travis Street in Houston.

***Beaumont, Liberty & Houston Traction Company, Houston, Tex.**—Surveys have been begun by this company for a line to connect Houston, Waco, Beaumont and Liberty. Offers of right-of-way and subsidies for the construction of the lines are being made by the land owners along the route. Edward Kennedy, president.

Mexia, Tex.—Preliminary arrangements are being made to build an electric railway in Mexia. The Commercial Club, Mexia, is interested. [E. R. J., Nov. 7, '14.]

San Antonio (Tex.) Traction Company.—This company has placed in operation its new line on Commerce Street from Soledad Street to Alamo Street in San Antonio.

Texas City (Tex.) Street Railway.—Work has been begun by this company on the 1-mile extension in Texas City to connect with the ferry lines between Texas City and Galveston.

Tacoma (Wash.) Municipal Railway.—Bonds for this railway have been bought by the Tacoma banks and construction work has been begun.

West Virginia Traction & Electric Company, Wheeling, W. Va.—Plans are being made by this company for improvements on the out-the-pike division of its line before the first of the year.

SHOPS AND BUILDINGS

Pacific Electric Railway, Los Angeles, Cal.—Work has been begun by this company on the construction of a new freight depot on F Street near Second Street in Los Angeles.

Holyoke (Mass.) Street Railway.—This company has moved into its new carhouse on Canal Street and Bridge Street in Holyoke. The old carhouse will be used for storage purposes and for car painting.

Minneapolis (Minn.) Street Railway.—This company has opened its new passenger station on Washington Avenue between Twenty-fourth Street and Twenty-sixth Street in Minneapolis.

Ohio Electric Railway, Cincinnati, Ohio.—This company has transferred all business from its old station in North Park Place to the new station in East Main Street, between First Street and Second Street in Newark.

POWER HOUSES AND SUBSTATIONS

Laurel Light & Railway Company, Laurel, Miss.—New machinery is being installed by this company at its power house in Laurel. The new equipment consists of an additional turbine of 1000-kw capacity, a new 300-kw railway machine and other equipment. The cost is estimated to be about $20,000.

Quebec Railway, Light & Power Company, Quebec, Que.—Plans are under consideration by this company for the development of additional power. The company has recently closed, or is now working on power contracts, aggregating 8000 hp. These include a contract for 2000 hp. with the St. Malo workshops of the National Transcontinental Railway, and a contract for 3000 hp for the government drydock at Levis. It was recently announced that a contract had been closed with the Ross rifle factory for an additional 600 hp.

Cleburne (Tex.) Street Railway.—Plans are being considered by this company to build a new power plant in Cleburne.

Manufactures and Supplies

ROLLING STOCK

Pacific Electric Railway, Los Angeles, Cal., noted in the ELECTRIC RAILWAY JOURNAL of Oct. 31, 1914, as expecting to purchase twenty-four all-steel cars, has ordered this equipment from the Pressed Steel Car Company.

Boston (Mass.) Elevated Railway has issued specifications for 100 center-entrance trail cars for use in the new Boylston Street subway. It is reported that the order for the cars will be placed early next week.

Hocking-Sunday Creek Traction Company, Nelsonville, Ohio, noted in the ELECTRIC RAILWAY JOURNAL of Oct. 31 as expecting to purchase three new cars, has ordered three all-steel cars, 44 ft. 6 in. over all in length, for double-end operation and seating capacity of 48, from the Cincinnati Car Company.

Charleston (S. C.) Consolidated Railway & Lighting Company, noted in the ELECTRIC RAILWAY JOURNAL of Oct. 10 as having ordered twelve all-steel city prepayment cars from the Cincinnati Car Company, has specified the following details for this equipment:

Seating capacity	41
Weight (car body only)	14,000 lb.
Length of body	28 ft. 6 in.
Length over vestibule	41 ft.
Interior trim	cherry
Roof	arch
Underframe	composite
Air brakes	G.E.
Axles	Midvale Steel Co.
Bumpers	Hedley
Cables	West.
Control	Type K
Couplers	Brill
Curtain material	Pantasote
Destination signs	Hunter
Fenders	H. B.
Gongs	Dedenda
Hand brakes	Brill, vertical wheel
Headlights	Golden Glow
Journal boxes	Symington
Motors	2 West. 323-V-2, outside hung
Paint	Flood & Conklin Simplex system
Registers	International
Sash fixtures	National L. W.
Seats	Brill Winner
Seating material	rattan
Step treads	Stanwood
Trolley catchers	O. B.
Trolley base	O. B.
Trucks	Brill 39-E
Varnish	Flood & Conklin
Wheels	Southern Wheel Co.

TRADE NOTES

Eclectic Film Company has appointed Edward Auger as manager of its branches in place of Arthur S. Kane, resigned.

Power Specialty Company, New York, N. Y., has removed its Chicago office from the Peoples Gas Building to the Harris Trust Building.

Edward C. Geither, formerly with the Ingersoll-Rand Company, has become affiliated with the Ellcon Company, 50 Church Street, New York. Mr. Geither will have charge of the sale of the E. M. B. unbreakable resistance, on which this company has recently secured American rights.

Graphite Lubricating Company, Bound Brook, N. J., has made a change in its "Bound Brook" bushing to give its customers positive proof that they are buying the genuine article. All they will have to do to convince themselves is to saw one bushing in two and the words "Bound Brook" will appear on the inside of the bushing.

Garrett B. James, of the engineering staff of the Underwriters' Laboratories, has been appointed by Secretary Lane of the Department of the Interior as consulting engineer in the bureau of mines, to carry on an investigation on the subject of oil fires. Mr. James has been granted a three-months leave of absence from the laboratories.

Walter A. Zelnicker Supply Company, St. Louis, Mo., has appointed Ralph H. Wilson as advertising manager. Mr. Wilson has been with this company about two years, first as assistant to A. R. Topping and later representing the company in the Southeast. Mr. Wilson's position as southwestern representative will be filled by E. F. Prichard, formerly auditor of the St. Louis Car Company.

Waddell & Harrington, Kansas City, Mo., consulting engineers, announce the dissolution of their firm. The firm's business will be conducted as usual until the conclusion of its affairs in July, 1915, except that it is accepting no new commissions. Dr. Waddell will give his attention to special engineering and financial matters and to important advisory work. Mr. Harrington will be joined by the firm's associate engineers, E. E. Howard and Louis R. Ash, in the establishment of the firm of Harrington, Howard & Ash. This new firm will conduct a general consulting practice similar to their past work, including hydroelectric developments, advisory municipal engineering, appraisals, examinations and reports upon engineering projects, giving special attention to foundations, bridges, particularly movable spans, and other structures in steel and reinforced concrete.

ADVERTISING LITERATURE

Dielectric Manufacturing Company, St. Louis, Mo., has issued a folder which describes standard specifications for using its "Steeltred" concrete floor hardener.

George T. Ladd Company, Pittsburgh, Pa., has issued Bulletin No. 16 which contains colored sectional illustrations of the Milne water-tube boiler.

Western Electric Company, New York, N. Y., has issued a new bulletin describing its switchboards. The bulletin is written in Spanish and is intended for use in Central and South American trade.

Wright Manufacturing Company, Lisbon, Ohio, has issued a catalog describing and illustrating its high-speed steel hoists, screw hoists, differential chain blocks, steel trolleys and hand traveling cranes.

Drew Electric & Manufacturing Company, Indianapolis, Ind., has issued a folder entitled "The Best Way to Prevent Boarding and Alighting Accidents," which describes and illustrates its motorman's safety mirrors for open and closed cars.

General Devices & Fittings Company, Chicago, Ill., has issued a folder illustrating its various high and low tension station devices, such as busbar supports, malleable iron fittings, insulator pins, clamp type supports, contact fittings and low tension switches, disconnecting switches and miscellaneous fittings.

General Electric Company, Schenectady, N. Y., has issued Bulletin No. 44,300, which illustrates and describes some of the gas-electric motor cars and locomotives built by this company. These cars and locomotives are adapted for branch line service on steam roads and also for interurban service. The prime mover is a gas engine direct connected to an electric generator which supplies current to the motor mounted on the axles of the front truck. The controller contains the necessary handles for regulating the generator voltage, controlling the motors and for throttling the engine and reversing the motors. The power equipment is described in considerable detail in the bulletin, and average cost of operation of the standard car is given in addition to other data relative to weights, dimensions, etc. A very attractive and profusely illustrated bulletin which contains a discussion of modern electric railway apparatus has also been issued by this company. The bulletin is contained in a colored cover of artistic design, and describes briefly the Curtis steam turbine for railway service, railway generators, transformers, switchboards, synchronous converters, motor-generator sets, ventilated railway motors, electric locomotives, and contains illustrations of the GE locomotives in use at the locks of the Panama Canal. The number of the bulletin is 44,003. Bulletins Nos. 44,403 and 44,405, also just issued, describe this company's ventilated commutating-pole railway motors for 600 and 600-1200-volt service. Bulletin No. 44403 is devoted to the GE-222-G railway motor, which has a rated output of 140 hp at 600 volts, and, having modified windings, can be supplied for operation with two in series on 1200 volts, at which voltage the rating is 130 hp. Bulletin No. 44405 describes the GE-233-A motor for operating two in series on 1200 volts. This has an hourly rating of 75 hp. Both motors are described in considerable detail, and each bulletin contains characteristic curves of the motors. Bulletin No. 46,018 describes the Type P-8 portable voltmeter. This is an unusually small instrument inclosed in a mahogany case and suitable for use on both alternating and direct current.

Electric Railway Journal

Published by the McGraw Publishing Company, Inc.
Consolidation of Street Railway Journal and Electric Railway Review

Vol. XLIV NEW YORK, SATURDAY NOVEMBER 21, 1914 No. 21

CENTRAL STATES PASSENGER RATE INCREASE The announcement of an advance in interstate passenger rates by the steam railroads in the central passenger district, effective Dec. 1, 1914, suggests a parallel increase in the passenger rates of electric interurban lines doing an interstate business in the central states. The rates on most interurban lines are less than those on competitive steam roads, so that if the latter's are increased the electric line can make a similar increase and still retain its share of the business. Perhaps a policy of "watchful waiting" at this time should be recommended, since the advance in steam railroad rates depends upon the approval of the Interstate Commerce Commission, but if this approval is granted the traffic managers of the interstate electric lines in the central states should be prepared to file jointly a new passenger tariff containing the advanced rates. Since these will not conform with the new rates of the steam roads an independent hearing will be necessary. A glance at a map showing the electric lines in the territory affected indicates that there are at least twenty that may be classed as interstate carriers. Most of these are members of the Central Electric Traffic Association which could serve as a nucleus for concerted action. Those who are not members should at once consider the feasibility of such an advance, and, if advisable, prepare to take advantage of this opportunity.

CONVENTIONS OF THE PAST TWO WEEKS Electric railway men are apt to think of October as the month of conventions, but during the past two weeks there has been a number, and papers or reports from five are reported at considerable length in this issue. It would have been impossible for any one person to have attended all of these meetings, because some of them occurred simultaneously. Nevertheless many of the papers and reports have an intimate relation with electric railway work and each represents weeks or months of study by experts on the subject treated, with often the collaboration of others equally well fitted to consider the subject. For this reason such a paper or report is of more value than an individual contribution on the subject treated. Finally, while many of these papers will be published in the official reports of the proceedings they will not be available for some time to the public, and the technical periodical supplies the only available means for most persons of obtaining information thus presented. We consider it one of the duties of a technical paper to report all matters of this kind in its field and that this is one of the best services which it can render to its readers.

FUNDAMENTAL PRINCIPLES IN MECHANICS The readers of technical journals such as this one cannot but note how essential is a knowledge of the laws of mechanics to an intelligent understanding of many of the articles. For example, in this issue are abstracts of two recent papers, one by J. F. Layng on "Selection of Electrical Equipment," the other by E. C. Woodruff on a "Graphic Method for Time-Speed and Time-Distance Curves." In Mr. Layng's paper the most interesting feature, from the present standpoint, is the application of the law of moments. In its lowest terms this law states that to have equilibrium a tendency to twist in one direction must be balanced by an equal tendency in the other. This tendency is, of course, expressed quantitatively as the sum of a number of moments or products of forces by the lengths of the respective lever arms through which they act.

LINEAR ACCELERATION OF A MASS Both of the discussions referred to above involve the relations of force, mass and acceleration. The qualitative relations of these are well understood in a practical way. For example, if an emergency brake application is made when we are standing in a car aisle we are apt to slide toward the front door unless we brace ourselves firmly. Similarly we long to leave by the rear door when the car starts suddenly. That is, we tend to continue moving when the car stops and to remain stationary when it starts. When a quantitative relation is desired all that is necessary is to apply the fundamental law: force equals mass times acceleration. By definition of the units of these quantities a pound of force is a certain force recently prescribed by law like the pound of mass. A correctly calibrated spring balance reads in pounds of force. The unit of mass is also the pound and it is the same pound. Now a pound of force uniformly exerted on a pound of mass produces a rate of acceleration experimentally determined at about 32.2 ft. per second per second, or 21.95 miles per hour per second. A ton of force applied to a ton of mass produces, of course, exactly the same result. Similar braking forces produce the same results in the opposite direction; that is, the acceleration is negative. This negative acceleration is sometimes termed "deceleration," although the expression preferred by most engineers is "retardation." This is the whole mater of linear acceleration in a nutshell. The electric railway man who is at all concerned with design or operation should have the laws of mechanics at his fingers' ends. Sound theory, reinforced with experience, is the only safe foundation for practice.

THE CONFERENCE OF MAYORS

An account of the meeting in Philadelphia last week of the mayors of American cities to consider public utility questions is published elsewhere in this issue, and the principal result accomplished was the decision to exchange information through a central bureau, or clearing house, as it was termed by Mayor Mitchel. This is a commendable step and should result in benefit not only to the citizens of the different communities but to the utilities which serve them. Ignorance of the real conditions has been found by the utilities in the past to be the chief obstacle to satisfactory contractual relations and good public feeling. If the utilities bureau is conducted by experts, as proposed, capable not only of collecting and distributing the information desired but also of analyzing and correctly interpreting it, and if it is carried on with the same sincere efforts to obtain all the facts which have characterized our best state commissions, the public utilities have nothing to fear. Otherwise the data will do more harm than good.

In view of the fact that the meeting was devoted largely to the question of utility regulation, it was but natural that the relative claims of municipal and state regulation should have occupied a prominent place on the program. It was also natural, in view of the composition of the meeting, that a great many of the speakers should have advocated regulation by the municipalities rather than by the states. The desire for power is present in every one, and most people, especially those who already hold an executive office, believe that they can administer other governmental functions better than those in charge of them. Nevertheless, no new arguments were presented in favor of municipal regulation instead of state regulation of public utilities, and the defence of the present plan of state regulation, especially by Messrs. Erickson and Guernsey, was logical and should be convincing.

It was perhaps not surprising also that the final recommendations advocate that in all instances municipalities should have the power to municipalize public utilities, the exercise of this power being a matter for local determination, and that all such municipal utilities should be subject to local control only. While both of these matters are to a very large extent concerns of the future, they are mischievous in the extreme. It is hard to imagine any argument in favor of the regulation of private utilities which does not apply with equal and greater force to those cases where the owner and operator is the city. In a municipally owned enterprise the public must be protected not only from unreasonable and discriminatory rates and from inadequate and unsafe service but also from inefficient operation resulting in a waste of the public funds. It is hard to conceive of any more serious condition into which a municipality can come than to have its utilities, with their immense opportunities for political strength, in the hands of an unscrupulous political organization, or even of an honest but weak and inefficient one, which can laugh with impunity at the efforts of the taxpayers to dislodge it from power. Both our state and national governments are based on the principle of legislative checks and of limited power to any one department of government, and any unregulated direction of its utilities by a municipality will present the same evils as a single chamber of government or the combination in one person or group of men of the functions of judge and jury.

PROTECTION BY FLAG IN ADVANCE

Our recent objections to the so-called revival of the flagging rule, which at one time indorsed the propriety of moving a train when it was protected by a man walking in advance, are based quite as much upon the general character of any such rule as upon its detailed form or method of application. This point is discussed in a communication by John Leisenring which appears elsewhere in this issue. Mr. Leisenring emphasizes the fact that the flagging rules recently adopted by several signaled roads differ in form from the old one and do not permit the advancement of meeting points. The correctness of this statement is manifest. Yet, no matter what the construction of such a rule may be, it is subject to inherent weaknesses which it seems to be impossible to avoid if the principle is retained.

One of the latest of the roads to reintroduce the rule has adopted the following wording: "When a train is stopped by a block signal . . . and is unable to communicate with the dispatcher, the conductor . . . will proceed to the next signal and be in advance of the train at least 1500 ft., at which distance the train may proceed to the next signal, expecting to find the block occupied, etc." This is, of course, decidedly preferable to the old wording that left the distance by which the conductor preceded the train largely to his own judgment. On the other hand, the new wording provides no means for the motorman to tell when he is 1500 ft. behind the conductor if the latter is out of sight around a curve or in a mist, and it calls upon him to exercise superhuman restraint in moving his car at the unaccustomed pace of 3 m.p.h. Even the conductor is called upon to walk the ties, when hanging onto the front end of the car would be far easier.

As a matter of fact, it is well established that such a rule is not going to be followed properly any more than is the present rear-end protection rule on double-tracked steam roads—an alleged precaution, that might just as well be abolished on signaled lines as to remain, as it does now, a constant incentive to infractions of discipline. If it was followed conscientiously and with good judgment, even the old flagging rule would serve as a means to make the operation of a train as safe as that of the rocking chair in the family parlor. The difficulty is that the rule won't be followed—neither conscientiously nor with good judgment; and, as we pointed out in our first editorial on this subject on Aug. 1, a comparatively small reduction in delay does not offset the possibility of accident (both direct and indirect) when perfect safety can be obtained by having the train wait until someone has gone to the next siding or the nearest telephone. This is emphasized by the fact that the combination can hardly occur at frequent intervals. One delay of thirty minutes or an hour every year or two is not much of an excuse for the existence of a flagging rule in any form.

However, we are heartily in accord with Mr. Leisenring's statement regarding the desirability of having this newly-arisen complication settled by the Transportation & Traffic Association, and as the ensuing committee on rules has been requested to investigate it there is no doubt but that a decision will be reached at the next convention. As we have said previously, the failure of the telephone at a defective signal leaves the motorman upon the horns of a dilemma from which he ought to be rescued by definite instructions in his book of rules. That these instructions should involve the procedure of movement under the questionable protection of a flag in advance is, however, entirely unnecessary, and, in our opinion, most undesirable as well.

LABOR CONDITIONS UNDER MUNICIPAL OWNERSHIP ABROAD

Among the reports submitted to the thirty-fourth annual convention of the American Federation of Labor in Philadelphia last week was one on labor conditions on European municipally-owned railroads. It would be a good thing if every employee of American electric railways could read this report. By comparing his own lot with that of the employees of both privately and municipally-owned railways abroad the platform men of the United States would be forced to the conclusion that their pay and conditions of employment are exceptionally favorable.

If the two representatives of the American electric railway employees who wrote this report, after a somewhat extended trip abroad, have heretofore harbored the belief that municipal ownership as practiced abroad makes any real difference in the condition of the trainmen, they have now changed their minds. They say that in spite of all the claims that have been made for foreign legislation helpful to workers and the blessings of municipal enterprise, they "found the living standards of the workers of Europe, tram as well as others, so far below the average of the workers of America that no comparison is possible." They also found that there was no comparison in the sense that there was only a remote parity between the wages of European tram employees and those of the United States. They estimate that the cost of living in the United States is from 25 per cent to 65 per cent higher than it is in Europe, but that the difference in the wages of the electric railway men of the two continents is much greater, the maximum and minimum wages here being at least twice as much as are paid abroad either on private or municipal systems.

In Germany it was found that the average minimum wage in 192 cities was $17.64 a month, and the average maximum wage for the same period $35.28. In a number of cities the maximum is not reached until after twenty years of service. This is the rule in Berlin, while in Munich the maximum of 210 marks ($52.40) a month is not attained until after thirty-one years of service. The minimum wage in Paris is $33 and the maximum $40 per month. In Rome the minimum is 64 cents a day and the maximum wage after eighteen years of service 94 cents a day. London pays its motormen and conductors from $1.20 to $1.56 a day. Glasgow has a sliding scale ranging from $6.48 a week for the first year to $8.16 for the seventh year; thereafter $8.40 a week.

Aside from the question of wages the contracts that tram employees are obliged to sign in Germany would be considered intolerable here. Among other requirements is one for a bond to cover any damage caused by the employee and to secure the turning in of apparatus, tickets, etc. The employee must also agree to a system of forfeits or fines for every case of contravention of orders, and must explicitly renounce all right of appeal from decisions of the management as to punishments that may be inflicted under this or other provisions of the contract.

In general the signers of this report say that the conditions of the European tramway workers are similar to those that existed among street railway men in the United States twenty years ago. In their conclusions they remark that the same "spirit of commercialism" dominates electric railway systems in Europe, both private and municipal; that if there is anything to chose in the matter of treatment of employees, preference must be accorded to the roads on this side of the water. Besides this, the investigators found that electric railway transportation here is not only cheaper but better and there is a great deal more of it. They explode the idea that European fares are cheaper than our own by saying that the zone system means dear fares to the worker if he has to ride any considerable distance or take intersecting lines. "Zone fares and inadequate wages force the workers of Europe to live close to the workshop, mill or factory. It is rare to find a European worker who can afford to live in the suburbs or country, miles away from his work, as is frequently the case here. The rate of fares for long distances make it prohibitive, and the wages will not warrant the expenditure. Thus the zone system contributes to congestion and compels the workers to live in the most uninviting districts."

Whether they intended to do so or not, Mr. Mahon, as president of the Amalgamated Association of Street and Electric Railway Employees, and Mr. Bland, the Chicago leader of the same organization and editor of its official newspaper organ, have in their report written one of the strongest of testimonials to the effect not only that American electric railway operation is so far in advance of that of Europe that there is no basis for comparison, but that in respect to the treatment of employees American roads with regard to wages, and in other directions, have established standards which should make the American railway man glad that his lot is cast here rather than in Europe. The next time that an attempt is made to prove that American electric railway employees are down-trodden and abused it may be convenient to have as testimony of European railroad labor conditions this report, which has been spread upon the records of the American Federation of Labor.

Rebuilding Cars in Los Angeles Railway Shops

The Standard Pacific-Type Cars of This Company Are Being Remodeled Into Center-Entrance Cars with a Low Step at a Very Moderate Cost—A Detailed Account of the Work Is Given

About 330 narrow-gage cars of the Los Angeles Railway Company are being remodeled at the company's Los Angeles shops to provide longer bodies, lower steps and center entrances. Interest attaches to the work because of the small amount of new material required and the resultant low cost of changes that develop an entirely different car. In spite of the radical departure from the lines of the old model and the reduction of 13 in. in the total height of steps, the same motors, trucks and brakes are being used again, and the rule of the company which requires the mechanical equipment for all cars to be interchangeable throughout is being strictly followed.

FEATURES OF THE NEW DESIGN

As long ago as 1908 a center-entrance car was suggested for the lines of this company. However, the plan did not meet with general approval at that time, and it was not until two years ago that the first car of this type was put in service for trial under local conditions. After experimenting with various features, a design was finally developed in May, 1913, which suited climatic conditions and embodied the ideas of the company officials. An order was then placed with the St. Louis Car Company for seventy-five cars of this design, and these have now been operating in Los Angeles to the apparent satisfaction of the public and the company for several months.

In addition to the new center-entrance cars which were purchased, forty-five of the old type cars have been converted into the new type, as illustrated, and all of these were in service by April 18 of this year. About 285 more will be rebuilt in the same manner. The remodeled car is 46 ft. 7 in. long, 8 ft. 5 in. wide over all, and has a seating capacity of fifty-four, although in the old cars there were seats for only forty-four passengers. The 30-in. wheels taken from the old-style cars are used, but the spacing between truck centers was increased from 23 ft. to 30 ft. 6 in. The total weight of the rebuilt car is 37,000 lb., or 500 lb. less than its weight before remodeling. The new car is divided into two duplicate halves by the central entrance, each half having both an open and a closed section. Longitudinal seats are installed in the closed sections, thus affording wide passageways in the car near the entrance, and seven "walkovers" and one stationary seat are provided in each open section.

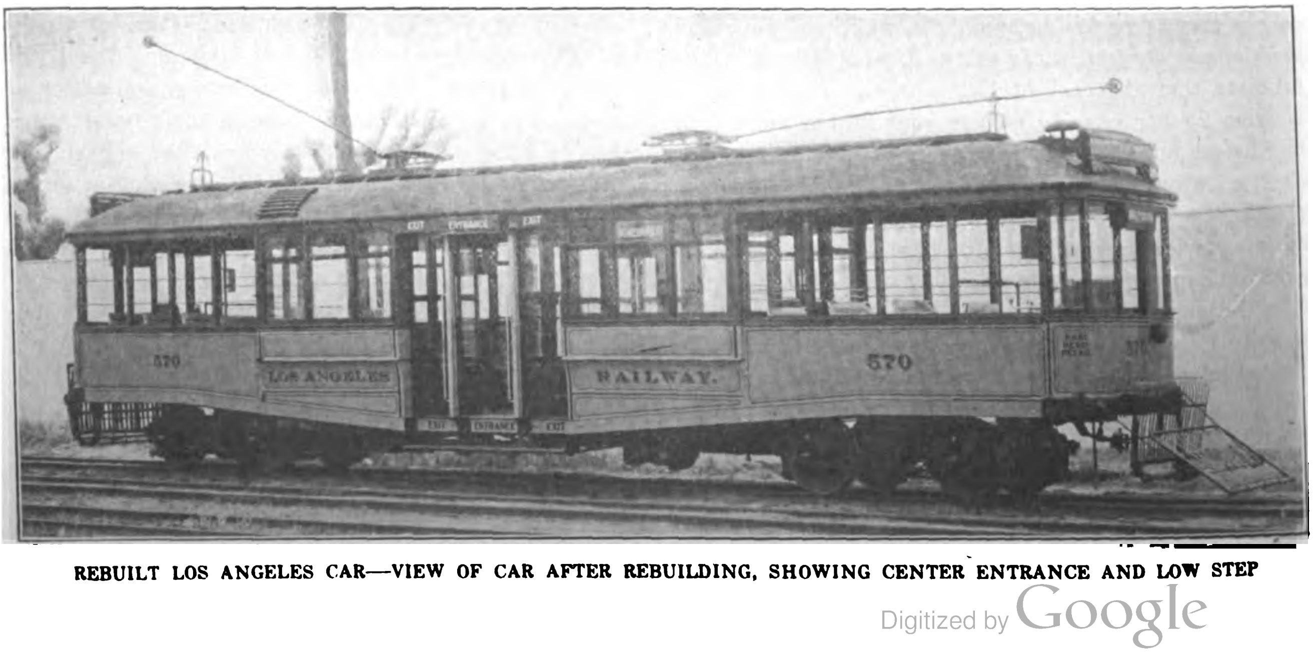
In the new cars a floor level 13 in. lower than in the old type at the steps is secured by sloping the floor upward toward each end so as to rise 8 in. in a length of 11 ft. 6 in. on both sides of the entrance. Another 2 in. is gained by a lateral slope in the entrance section, where the floor inclines from the doors toward a level 2 in. higher on the center line of the car, and the remaining 3 in. were gained by shortening the springs and making other minor changes in the trucks.

There is no step inside the car, and the only one outside has a 10-in. tread. This is set back into the frame so that its edge is flush with the side of the car. The double-leaf entrance door is normally kept open, and the exits are normally closed. All swing on ball-bearing sockets, and a single 5-in. lever at the conductor's station is sufficient to operate both exit doors with ease. The connecting levers operating the exits are below the floor, and those for the entrance are overhead. In both cases the doors are locked by throwing the hand lever past the center.

Remodeling the cars afforded an excellent opportunity to carry out new ideas in the arrangement of routing signs, and the system that was adopted is shown in one of the illustrations. These signs were built up entirely in the company's shops. The lettering on the large signs at the head end is painted on hollands similar to a strong, highly transparent tracing cloth. This material is 58 in. wide, and each sign is 40 ft. long, this being sufficient for the entire fifty-four routings under which the cars of the system operate. The edges of the cloth are bound with a flexible copper ribbon which prevents stretching, creasing or tearing. These head-end signs are illumined by three 64-watt lamps.

In the new equipment an illuminated reflector is located over the exit and entrance doors which not only furnishes light for the steps but is so located that it lights up the whole side of the car. This enables the motorman to have a full view of the side of the car and the steps with the aid of an adjustable mirror attached to the vestibule post.

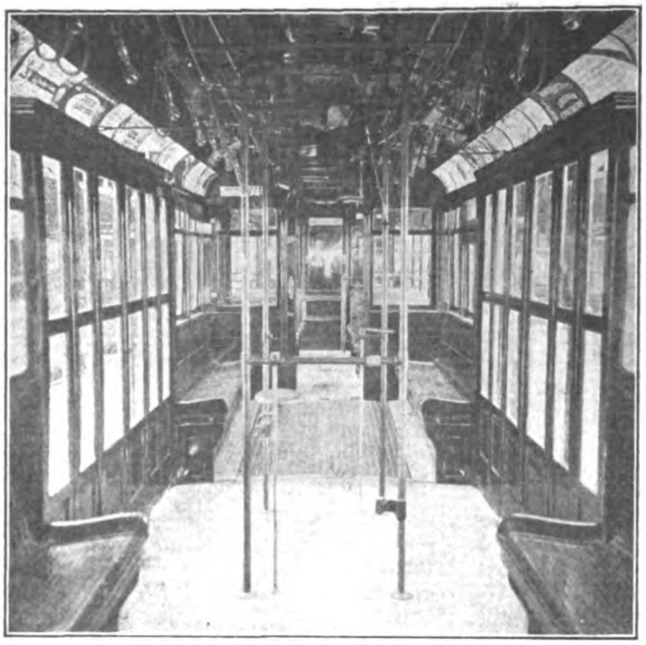
The motors on the old cars are 55-hp, 600-volt West-



REBUILT LOS ANGELES CAR—VIEW OF CAR AFTER REBUILDING, SHOWING CENTER ENTRANCE AND LOW STEP inghouse No. 38-B, and these are being used again in the rebuilt cars. The cars of the center-entrance type which were purchased new, however, are equipped with 60-hp, 600-volt, No. 306-L Westinghouse motors, and the latter are now specified when purchasing motors.

The old Westinghouse 38-B motor was originally constructed for a 4-in. axle, while the 306-L motor is constructed for a 4½-in. or 5-in. axle. As the 4½-in. axle was adopted to make an interchangeable standard axle, gear and wheel combination, it became necessary to rebore the old 38-B motors, and this was done by the use of a jig which was developed for this purpose. As many of the old motors were becoming worn at the armature-shaft bearings it was decided to rebore the shells at the same time as the axle bearings, and by the use of this jig it was possible to rebore all four bearings in a single operation, giving perfect alignment. One man has been able to rebore six motors per day with the machine, and more than 800 motors have been rebored in this manner.

It has been found that although the No. 38-B motors have given satisfactory service on all lines of the company, the hill districts can be better served with the No. 306-L motors, and so far as possible the cars with these larger motors are now being assigned to the more hilly routes.



REBUILT LOS ANGELES CAR—INTERIOR VIEW

DETAILS OF RECONSTRUCTION

It was found most advisable in the rebuilding work to gain the desired 7 ft. 6 in. of length by cutting the cars in two in the middle and splicing in a new section. Incidentally this new section was designed so that it embodied the radical changes desired in the new cars, and thus many alterations that would otherwise have been necessary were avoided. In this work the upper deck of the roof is taken off and the ventilator sashes are removed. Then, by using false rafters from the top plate to the deck sills and putting in the extra length at the center an arched roof is built with practically all the old material, even the headlining being replaced.

In rebuilding the floor framing, two new longitudinal sills are used. These are 4-in. 10¾-lb. I-beams, and they are bolted together on the center line of the car, while the two 5-in. 14¾-lb. I-beams used in the old car replace the old side sills. These beams are bent cold to conform to the depressed center floor level, and the two old beams are lengthened at opposite ends of the car by extra pieces, each firmly riveted to the old beams by two ½-in. splicing plates. The ½-in. x 7-in. sill plates of the old car, which are also a part of the floor framing, were neither the right width nor shape for the new design, but they were made to serve the purpose as well as new material at a considerable saving. These plates were first straightened and then put in the planer to be cut down to the ½-in. x 6-in. size desired. They were then cut in two at the middle, bent to the new shape and taken to the electric-welding shop. Here the 7 ft. 6 in. additional length was welded in at the center, the shape of the inserted length being suited to the feature of having the step recessed within the car body. The old bolt holes were welded up with new material, and the remodeled plates are said to be satisfactory in every way. The progress with the electric welding outfit is said to be such that a single operator easily turns out three times as much work as was formerly done by two blacksmiths.

In the remodeled cars the window frames and sashes are replaced, and the body posts are lengthened to conform to the sloping floor. The bench seats of the in-

REBUILT LOS ANGELES CAR—LATHE EQUIPPED WITH JIG FOR REPAIRING BEARINGS OF OLD MOTOR

closed sections are sloped 1¼ in. in 6 ft. to relieve the variation caused by the incline of the floor. Maple flooring is used in the entrance section, and pine, covered in some places with a steel mat, is used in all other parts of the car. In the entrance section four stanchions extend from floor to roof, and a removable bar, which can be used in either pair of these, serves as a barrier to limit the passageway and permits the conductor to stand behind the fare box and entirely out of the way of passengers.

Although the same control equipments are used again in the remodeled car, these are not placed on the center line as before but are located at the right-hand corners of each end of the car where the motorman's space is closed off by stanchions and crossbars. Both conductor and motorman are provided with removable seats which can be adjusted to any desired height on the stanchions.

The repair shops of the company are so equipped that they can handle all parts of the work involved in transforming the cars. The cars to be rebuilt are moved from place to place in the shops by means of transfer tables, and by distributing the various parts among the proper departments the rebuilding is carried on expeditiously. This is greatly facilitated by the company standard, which requires all parts to be interchangeable. The regular force of the company handles the work, and when not interrupted by special orders or rush repairs on disabled rolling stock it can turn out the rebuilt cars at the rate of three per week. It is interesting to note that when the rebuilding was first undertaken the progress was less than half this rate.

A careful system of accounting is in vogue in every department, so that a close check is kept on the cost of each branch of the work. Typical of this is the paint storeroom, where three experienced men mix all the paints used in the shops. When beginning work the car painters go to this room and receive paint and brush over a counter. The paint is weighed and charged up to the job as it goes out, and whatever comes back is deducted from the original charge. Brushes are cared for every night by the three regular paint-room men.

The work of remodeling the cars will probably not be completed until some time early in 1916, and at the present time exact cost figures are not available. It may be said, however, that judging from the cars already turned out the cost of materials and labor is estimated to be $678 per car, distributed as follows:

Labor	$165
Signs	118
Wiring	80
Painting	160
Materials	155
Total	$678

Comparing this with the $3,000, which is approximately the cost of a new car body of the same type, the economy of the plan is obvious. It is to be noted that the cost of remodeling is considerably increased by the signs, which are an entirely new feature, as well as by the necessity of entirely repainting and refinishing all parts.

The design of this center-entrance type of car, as well as the general scheme of the remodeling, was worked out by E. L. Stephens, master mechanic Los Angeles Railway, under whose personal supervision all work at the repair shops is carried out.

Investment Bankers' Association Convention

A Brief Account of the Proceedings at the Third Annual Convention of the Investment Bankers' Association of America in Philadelphia on Nov. 12-13—List of New Officers—Abstracts of Papers and Committee Reports of Interest to Electric Railway Officials

The third annual convention of the Investment Bankers' Association of America was held on Nov. 12-13 in the Bellevue-Stratford Hotel in Philadelphia. The president's address, which was abstracted in the ELECTRIC RAILWAY JOURNAL of Nov. 14, was delivered by George B. Caldwell, Chicago, on Thursday morning. This was followed, among other things, by a committee report by John E. Oldham, of Merrill, Oldham & Company, Boston, on railroad rates from the investor's point of view, and a report on railroad bonds and equipment notes by Samuel L. Fuller, New York. At the afternoon session on Thursday, an address was delivered by Rudolph Diamand, A. B. Leach & Company, New York, on the subject of "Investment Bankers and the Federal Reserve Law."

At the Friday morning session Andrew J. Frame, president Waukesha (Wis.) National Bank, presented an address on "An Equitable Solution of the Public Utility and Conservation Problems." On Friday afternoon two addresses were delivered as follows: "The Existing Steam Railroad Situation," by William H. Coverdale, president William H. Coverdale & Company, Inc., New York, and "The Modern Gas Company as a Security for Bonds," by Rufus C. Dawes, president Metropolitan Gas & Electric Company, Chicago. The papers and committee reports mentioned are abstracted below.

The following officers and governors were chosen for the ensuing year: President, A. B. Leach, A. B. Leach & Company, New York; vice-presidents: Frank W. Rollins, E. H. Rollins & Sons, Boston; Allen G. Hoyt, N. W. Halsey & Company, New York; John E. Blunt, Jr., Merchants Loan & Trust Company, Chicago; J. W. Edminson, William R. Staats & Company, San Francisco; Charles A. Otis, Otis & Company, Cleveland; secretary, Frederick R. Fenton, Devitt, Tremble & Company, Chicago; treasurer, J. Herndon Smith, Smith, Moore & Company, St. Louis; governors: Lewis B. Franklin, Guaranty Trust Company, New York; Charles W. McNear, C. W. McNear & Company, Chicago; Warren S. Hayden, Hayden, Miller & Company, Cleveland; George W. Kendrick, III, E. W. Clark & Company, Philadelphia; Lawrence Chamberlain, Kountze Brothers, New York; William R. Compton, William R. Compton & Company, St. Louis; William G. Baker, Jr., Baker, Watts & Company, Baltimore; John E. Oldham, Merrill, Oldham & Company, Boston, and Charles H. Gilman, Charles H. Gilman & Company, Portland, Maine.

SECURITY FOR BONDS

The address by Mr. Dawes, while dealing particularly with the subject of the "Modern Gas Company as Security for Bonds," brought out some ideas regarding general bond security that may be of interest to electric railway officials. According to Mr. Dawes, the interests of bondholders are generally best protected by preserving as much freedom as possible to those operating the property, the ownership of the equity and the operation of the property being in the hands of honest and capable men, whose leading motive must always be the protection of the bondholders. Under other conditions, in spite of skilful trustees and favorable business opportunities, the interests of the bondholders may be jeopardized.

Continuing along this line, Mr. Dawes remarked that in order to serve a growing community or to supply new demands, new funds must be provided through the increase of some form of liabilities, floating indebtedness, mortgage indebtedness or stock issues. Under proper restrictions this ought to be cared for by the issuance of additional bonds on a parity with those originally issued. A closed issue or an authorized issue too small is an injury to the bondholders. Similarly, a burdensome sinking fund may hamper a company in its ability to serve the public. The ability of the company to retire its bonds at maturity is not determined by the amount of the bonds outstanding at that time but by the ratio between the amount of its stable net income and the amount of the bonds outstanding. Preservation of the stable net income is the best protection for the bondholders, and withdrawals for sinking funds should never be so large as to interfere with this. Corporation bonds that are good are never retired but are refunded, for the financial utility of bonds to the community at large, both as promoting enterprise and as providing investment, is such that to retire well-secured bonds would be a double calamity.

In Mr. Dawes' opinion, bonds should offer stable net income upon the capital invested and the sure return of the capital at maturity, with reasonable facility for conversion into cash at any time. The best assurance of steady income is that obtained from a business supported by the public at large and supplying the public with a public necessity. Such a business operates under conditions that invite the interference and protection of the government for the continuation and regulation of the supply, and the fundamental principle of such regulation is the recognition of the right of the investment in the property to a reasonable rate of return.

INVESTMENT BANKERS AND THE FEDERAL RESERVE LAW

According to Mr. Diamond, there will be less reason for metropolitan bankers to hold bonds for permanent investment under the new federal reserve law, because the Aldrich-Vreeland act expires and bonds cannot be used to take out emergency circulation and because these banks will have a broader opportunity to use their funds for acceptances and other paper. As far as the carrying of bonds in loans or the offering of facilities to banking houses to handle their business is concerned, however, these will not be substantially restricted. Mr. Diamand considers in this connection that our national banks have previously invested a much larger amount in bonds than the banking institutions of any other country. He also said that 37.6 per cent of all the loans were based on stocks and bonds and feels that this represents too large a part of the resources to be invested in fields in close direct or indirect contact with the stock exchange.

Mr. Diamand believes that bankers in the small cities will find conditions under the federal reserve law approximately the same as in the past and that such banks will be disposed to invest 50 per cent of their surplus moneys in bonds and 50 per cent in commercial enterprises. The proportionate investment in stocks as compared to bonds will undoubtedly follow the same course as in the past.

With business in its present depressed condition, it is not believed that banks will be disposed to push back into the market very large amounts of bonds, certainly not until prices more nearly approach the purchase price. In the long run there may be a change in the character of the investment of the banks in a large city, but this change will come slowly. In discussing the dumping of European-held American securities on our markets as a result of the war, Mr. Diamand says that he does not believe that there will be any great influx of American securities from foreign countries, and even if there were any the sales would not come rapidly.

In concluding, Mr. Diamand said that the federal reserve system would tend to stabilize interest rates, would result in a broader and better banking system, would help to eliminate serious credit disturbances and would enable investment bankers to recommend with more confidence the securities of different corporations.

EXISTING STEAM RAILROAD CONDITIONS

Mr. Coverdale in his address on the above subject said that the ability to comprehend present railroad conditions and the courage to act upon them cannot be secured by working back to pioneer days of railroading and endeavoring to reconstruct the development with all its milestones of success and skeletons of failure, by trying to measure the record of the past with a personal yardstick of present financial morality or by stirring up factional disputes regarding rates, dividends, service and the like. As first aid to the injured income account and crippled credit of to-day, Mr. Coverdale offers a panacea of nonpartisanship which permits and encourages an impartial investigation. He would then apply the panacea by acquiring first-hand knowledge on the points involved and endeavor to secure a bird's-eye view of the relative merits of the different claims determined. Only in this way can the broad question of railroad economics be analyzed and its various practices properly correlated.

In discussing the various factors involved in the present situation, Mr. Coverdale assumed that certain railroad maturities are impending and that certain defaults exist which must be cured through some process of reorganization. In his opinion, the first point to be remembered is that the economic soundness of a proposed expenditure should receive consideration. The final costs of the proposition should be determined by the bankers as well as by engineers. Mr. Coverdale quoted a remark made by Samuel Insull last year before the convention to this effect: "It is not the price of coal or labor but of money that governs." With the economic soundness of the proposed expenditure determined, it then devolves upon the officers, owners and bankers to work out a practical plan or some practical modification of that existing. All securities issued under any new plan should be bounded on the north and the south by the value of the property and on the east and west by its income. When the whole of the capital liabilities is kept within these bounds their distribution into several classes in appropriate amounts is easily accomplished.

Mr. Coverdale next described the average investor's knowledge of the value of the property back of his investment, which may be summed in the paraphrase: "His not to reason why, his but to blindly buy." Mr. Coverdale urged investment bankers to conduct a thorough investigation of the relation which the amount of the lien bears to the value of the property, avoiding liens beyond whose bulky outline no sign of equity can be discerned with the naked eye and also that ingenious combination of equipment note and refunding mortgage which carefully insures a perpetual liability against a fast dwindling asset.

In regard to the inability of the average investor to make an adequate study of the property and accounts of the company, Mr. Coverdale said that investors should depend on investment bankers. The latter should be prepared to fulfil their duty to the investors. Better conditions can be brought about by investment bankers and their associates whose effective co-operation at the time of marketing securities is evidenced by underwriting syndicates and by combined selling organizations. They should make the general design and write the general specification of every security authorized and the detailed design and the detailed specification of every security issued.

As the investment banker is the temporary link between the company and the investor during the marketing period, so the trustee is the permanent link between them during the life of the indenture, and as the function of the banker should be enlarged to govern the making of the security, so the function of the trustee should be enlarged to govern the control of it after it is made. Indentures should cease to specify the duties of the trustees at great length and then relieve them of responsibility by allowing them to decide between parties by merely accepting a statement from one of them. As long as some trust deeds provide that bonds may be issued to cover maintenance expenditures, renewals and even interest charges, the trustees will be powerless to protect either the property or the bondholders.

Mr. Coverdale said that within five years 90 per cent of the present railroad mileage can be made sound. He criticised the usual process of reorganization through a receiver as adding an additional load to an already burdened property. One of the receivers is often the officer responsible for the bankruptcy, in so far as it may have been caused by operating conditions. As such he has immediate opportunity to accomplish under sanction of the court and through the issuance of receivership certificates what he was no longer able to do on the credit of the solvent company. If railroads rise under such a treatment, it is in spite of the low vitality which such a course entails. A saving element is the work of representative committees which have a way of ascertaining facts accurately and assimilating them quickly. Instead of working in terms of securities only, they work in terms of values, income, securities and property requirements.

Mr. Coverdale stated that the proportion of efficiency among officers and directors is often greater than the proportion of mileage whose record as to values, credit and income is unassailed and unassailable. In nearly all cases in his experience where railroads had required reorganization, the underlying causes have been far beyond the reach or control of the officers and directors.

In closing, Mr. Coverdale mentioned the necessity for higher rates and said that as close supervision and regulation at the hands of investment bankers will benefit future issues of securities, so the proper regulation of rates may improve and maintain their stability. It was his conviction that the needs of the railroads in this country are far greater than the operating results to be obtained from the maximum of human efficiency under existing rate conditions.

REPORT ON EQUIPMENT TRUSTS

The report of the committee on railroad bonds and equipment trusts was devoted almost entirely to an analysis of the present situation regarding equipment bonds and notes and the suggested improvements to be incorporated in indentures backing up such securities. As a result of its investigations since 1912, the committee concludes that the whole question of equipment trusts and the sufficiency of equipment as security for the equipment trust is one which goes into the very heart of the theory and practice of railroad accounting. While conditions affecting the management, auditing and financing of corporations have undergone many changes tending to safeguard and protect the investor's interest, it is the opinion of the committee that the indenture securing equipment trusts and railroad bonds has developed more and more to enable the borrowing corporation best to serve its own ends rather than to protect the investor. Under such conditions the principal matters which should be considered in the drawing of equipment trust indentures are grouped under the following heads:

1. PROPER VESTING OF TITLE OF TRUSTEE:

The trustee has to be protected against (a) attachment and judgment creditors of the railroad; (b) purchasers for value and subsequent mortgages of the railroad company; (c) prior mortgages which contain the usual after-acquired property clause covering rolling stock. The existing special rolling-stock recording acts which have been passed in practically every state and in Canada protect the trust against the first two classes of claimants if the trust agreement is properly recorded. With regard to prior mortgages, it is extremely important always to provide that no part of the equipment covered by the trust shall be delivered to the railroad prior to the execution and filing for record of the agreement, and the agreements for the construction of the cars should be made directly between the car manufacturers and the bankers or the trustee of the equipment trust.

The committee says that railroads have been lax in respect to such details in recent years. Moreover, various schemes have been prepared by which individuals or car companies have acquired cars from time to time for the uses of a particular railroad, arranged for leases of the equipment to the railroad and thereafter sold equipment-leased certificates to bankers. Such arrangements are open to question on the ground that these individuals are usually either the railroad itself in a different form or individuals who are agents of the railroad. The committee in this connection does not refer to the form of equipment trust issued under the so-called Philadelphia plan.

2. MAINTENANCE OF EQUIPMENT:

While almost all equipment trusts have provisions in the indentures requiring that the equipment shall be maintained or replaced, it has not been the practice of many trustees or of the banking firms handling equipment trusts to require that such provisions be carried out. Often new equipment has been purchased when repairs to existing equipment would have made the new purchase unnecessary. The committee feels that regular reports should be made to the trustee by the railroad covering the condition of the equipment pledged. The committee has submitted forms to be used in rendering such reports.

3. FUNDING THE PAYMENT OF PRINCIPAL AND INTEREST:

The committee found in looking over a number of indentures that no provision had been incorporated to prevent the extension of such maturing obligations. In order to safeguard against this practice, it recommends that the necessary funds sufficient to pay the principal and accrued interest of notes as they become due be deposited with the trustee and that when such notes are paid they be cancelled and no notes in substitution of them issued. No purchase or sale of notes or advances upon the same should operate to keep equipment notes alive after maturity.

4. ENFORCING CLAUSE:

An enforcing clause should be included in the indenture to enable the trustee to declare a default if the provisions of the indenture are not lived up to by the railroad. The trustee should be furnished with complete drawings describing the equipment so that in case of default it may have a full record to enable it to effect the sale of the equipment for the protection of the trust.

In the opinion of the committee the responsibility of the investment banker does not cease with the sale of the equipment trust certificates to his clients. The greatest evil to-day in connection with these securities is the neglect of investigation and regular oversight. The investment banker should make himself familiar with what provisions should be included in a properly drawn indenture securing equipment trusts. He should refuse to handle equipment trusts unless the indentures are properly drawn, and he should guard his clients' interests regularly and systematically by seeing to it that both the trustee and the railroad live up to the terms of the agreement.

EQUITABLE SOLUTION OF PUBLIC UTILITY PROBLEMS

According to Mr. Frame, the best authorities agree that the difference between private and public ownership and management of any utility approximates 20 per cent in favor of individualism. This 20 per cent spells human progress as compared to human decay. Mr. Frame believes that the greatest progress lies in individual ownership and management of public utilities subject to government supervision, but such supervision must permit of reasonable profits.

For solving public utility problems Mr. Frame suggests that all public utilities should be under the control of the United States Corporation Bureau or the Interstate Commerce Commission for interstate enterprises and under state commissions for state enterprises. Stock issues should be limited to the actual values turned in to the corporation, the cost of incorporation and interest on money advanced during construction, as well as a percentage of stock to cover a reasonable risk, not to exceed 10 per cent. Bonds should be limited to not more than 75 per cent of the total cost. Non-competitive charters should be granted for not less than twenty years at rates sufficient to pay annually a net profit of from 6 to 8 per cent, according to the risk involved. In arriving at the net profit deductions should be made for salaries and labor bills, adequate depreciation charges, reserve for accidents and extraordinary risks, interest on funded debt and cumulative dividends of from 6 to 8 per cent. The net profit above these amounts should be divided equally between the municipality or state or nation and the stockholders.

Additional stocks should be issued only for permanent improvements on the approval of the commissioners. Present outstanding stocks should remain, to be equitably adjusted whenever the corporation asks for an increase of stock. Charter extensions should be granted for twenty years and rates readjusted for service according to the average annual profits for the last twenty-year period. Mr. Frame believes this twenty-year average is equitable on account of the economic maxim that "waves of prosperity follow those of adversity."

Mr. Frame would apply the above plan not only to public utilities but with equal force to undeveloped water powers, coal mines, etc. In the case of public utilities non-competitive time charters seem necessary, but in the case of conservation of natural resources only absolute ownership with a share of net profits to the state will insure quick development.

Mr. Frame cites the city of Chicago as an example of how this plan of dividing the net profits may be worked out. He says that this city has received more than $10,000,000 in the last ten years as its share of profits on a straight 5-cent fare. This, he admits, is not a criterion of what to expect from all public utilities because large profits come only in great cities. To his mind, excessive corporation profits, except in rare cases of superior management, are a popular fallacy.

RAILROAD RATES FROM THE INVESTOR'S POINT OF VIEW

The paper by Mr. Oldham pointed out that the cost of capital cannot be neglected in adjusting railroad rates and showed that the adjustment of rates on the basis of any assumed rate of return will not provide a settlement of the question which will stand without alteration under changing conditions over any long period of years. On the present basis of railroad capitalization represented by the most conservative roads, an increase of 1 per cent in return on capital involves an increase of 5 per cent in income.

The author analyzed the financial condition of nineteen of the best railroad systems as averaged from 1900 to 1909, when railroad investments were in general favor, with operations in 1913, admittedly a year in which the securing of new capital was difficult on reasonable terms. In 1913, for every $100,000 of gross earnings, there was a capitalization of $505,000, and on this there was available for interest and dividends $32,300, or 6.4 per cent, compared with 6.8 per cent on a capitalization of $540,000 in the earlier period. There was actually paid in interest and dividends $26,200, or 5.2 per cent, as against 5 per cent in 1900-1909. There was left a surplus of 1.2 per cent on capital in 1913 compared with 1.8 per cent in the ten-year period. It is a mistake, however, to deduce from these figures that the railroads are in a prosperous condition. Owing to reductions in fixed charges due to the refunding in the ten-year period of more than $300,000,000 of bonds bearing interest at from 5 to 8 per cent, to increased efficiency of management and to the ability of the railroads to draw upon previously accumulated surplus earnings for property improvements, the railroads have been able to make the 1913 showing. The expense of financing the railroad business in order to gain $100,000 gross earnings is not stationary, any more than the cost of operation, and in view of the higher prices in recent years of labor and materials and the increasing demands for improved service, the conclusion should not be hastily drawn that because the face value of the capitalization was less in 1913, it required less actual investment to obtain $100,000 in revenue. The importance of the surplus in relation to railroad and any other form of public utility financing is very great.

After explaining fully the favorable circumstances which have kept the railroads from making a showing which is a true index of the present conditions, Mr. Oldham pointed out that the final test of the situation in public utility financing is the willingness of the investor to purchase permanent securities. The forced reliance of the railroads upon short-term borrowings indicates that present earnings do not yield a sufficient return to attract capital. The rate required by investors advanced in the period under consideration from ½ per cent to ¾ per cent on bonds and 1 per cent to 1½ per cent on stocks. The advance in payment by the railroads on their capitalization, however, rose only from 5 per cent to 5.2 per cent, and it was necessary to cut down the surplus which existed as protection from 1.8 per cent to 1.2 per cent. The cost of capital must necessarily include sufficient surplus to protect the actual return on capital.

Whether the rates for capital are low or high is a matter of comparative indifference if the cost of money and the necessary protection are recognized as forming a necessary part of the rate. The free entrance of capital into the market for railroad securities will mark the point at which the investors consider the readjustment to be effective. The events of 1914, and their effect upon the market for capital, indicate that a sufficient readjustment to meet the conditions of 1913 would still fall short of meeting the present conditions. The readjustment necessary to re-establish credit for the best railroads would still fail to give credit to the average roads. The minimum readjustment would probably be such as to insure a return on capital of from 30 per cent to 35 per cent of gross earnings, with a cost of service of from 65 per cent to 70 per cent, as compared with an actual service cost of 74.3 per cent for 1913.

Joint National Committee on Electrolysis

A meeting of the joint national committee on electrolysis was held in New York on Nov. 13. The personnel of this committee and of its sub-committees was given in the issue of the ELECTRIC RAILWAY JOURNAL for April 4, 1914, page 763, and its plans were commented upon editorially in the issue for June 27, page 1428. The purpose of the meeting was to receive and discuss the reports of the four sub-committees appointed last spring. These sub-committees with their respective chairmen were as follows: On principles and definitions, E. B. Rosa; on methods and analysis of surveys, J. D. von Maur; on foreign practice, Philip Torchio, and on domestic practice, F. N. Waterman. The sub-committees presented full reports which, after discussion, were referred to a committee of eight members for revision and editing, preparatory to publication. The report is, however, to be submitted to the full committee for approval before it is finally released. There were present at the New York meeting the following, representing the interests indicated: R. P. Stevens—American Electric Railway Association; E. B. Katté—American Railway Engineering Association; Philip Torchio, L. L. Elden and D. W. Roper—National Electric Light Association; H. S. Warren, F. L. Rhodes and A. P. Boeri—American Telephone & Telegraph Company; B. J. Arnold, chairman, and Paul Winsor—American Institute of Electrical Engineers; E. B. Rosa, secretary—National Bureau of Standards; F. Towle and S. S. Wyer—Natural Gas Association; and A. F. Ganz, J. A. Gould and J. D. von Maur—American Gas Institute.

Interborough Rapid Transit Signals

In the Oct. 31 issue of the ELECTRIC RAILWAY JOURNAL on page 1010 it was stated that the signals on the subway division of the Interborough Rapid Transit Company were "controlled by a single-rail-return track-circuit system which was installed in 1903 by the Union Switch & Signal Company." This statement should be elaborated to express the fact that, while the original installation was furnished and erected by the signal manufacturers, all subsequent modifications, extensions and improvements for the system, or approximately 50 per cent of the whole, were erected by the forces of the signal engineer's department of the Interborough Rapid Transit Company. All material for these additions to the original installation was furnished by the original manufacturer, but since the year 1905 the railway company has been doing all of its own erecting work.

Labor Conditions in Europe

Report Presented at Meeting of American Federation of Labor at Philadelphia Last Week—Wages Lower and Transportation Conditions Poorer in Europe than in America

At the annual convention of the American Federation of Labor in Philadelphia last week there was a special report entitled "Labor Conditions on European Municipally Owned Railroads." It was presented by W. D. Mahon and L. D. Bland, who visited Europe last summer in accordance with the following resolution adopted last year at the Seattle convention of the federation.

"Whereas, the question of municipal ownership and operation of street and electric railways is being considered by a number of the municipalities throughout the United States; and

"Whereas, this is an important question to the thousands of organized workers in the various trades and callings that follow this line of employment; therefore, be it

"Resolved, That the president and executive council of this American Federation of Labor are hereby instructed to make a thorough investigation as to the wages and hours of labor and the conditions of employment, including the rights of the employees to collective bargaining and the protecting of their labor through organization in such countries as have already adopted and are now operating their street and electric railways under municipal ownership, the results of this investigation to be submitted to the next convention of this federation with recommendation thereon."

An abstract of the report is printed below:

GERMANY

Of the 209 tramway systems in Germany, 134 are in the hands of private companies while the other seventy-five are owned and operated by local administrative bodies, districts or municipal councils. In some cases there is joint ownership by the municipalities and private parties, and there is a tendency to place the operation of these jointly owned properties in the hands of private parties to avoid the responsibility of operation and of dealing with the labor question.

Organizing the street railway workers of Germany has proceeded with great difficulty and under trying circumstances. It is claimed by some that the tramway employees have no legal right to organization. Old age, sickness and accident insurance are compulsory by law. According to Mr. Rathmann, the tramway representative of the Transportation Workers in Berlin, "A sudden rush to join the organization as soon as it is worth while, that is, to secure an increase in wage, and quite as sudden a rush to leave it as soon as the movement is over, seems to be a peculiarity of the tramway men, which in spite of all educative efforts of our union we have not been able to exterminate up to the present."

The report adds that although the German union, during the past three years, has fought on behalf of no less than 36,631 employees for an increase of wages, the records for 1912 show that among all these numbers there were but 8528 in good standing in the organization. The strikes of German tramway employees have been of short duration, the longest on record being three weeks. This occurred in Königsberg in 1912.

Under the head of "working conditions" the report says that the organized workers of Germany have no general labor contracts as in the United States. All contracts are made by the individual worker with his employer. He makes a contract to cover his probation period, then after he is accepted as a regular man, he makes another contract. Except as the organization has been successful in modifying them, the contracts are severe in their demands, restrictions and penalties.

The following are some of the working conditions of German tramway employees, according to the report, except that the money is translated into American currency:

"A man going to work on the trams must practice for eight weeks to learn the business. This is a government regulation. For that work he gets 60 cents a week. He must also put up an indemnity in the way of a forfeiture, averaging about $18, and this stands against him, indemnifying the company in cases of breakage or any violation of the company's rules and regulations, for all concerns have a system of fines ranging anywhere from 24 cents to as high as $3.60 or $3.84, which are imposed for the violation of rules and regulations. So if a man should fail to report in the morning and lose his run he would be fined from 24 cents to 48 cents for such offense.

"The medical test in the tramway service throughout Germany is very rigid. In addition to answering satisfactory specific questions pertaining to military service, an applicant must undergo a thorough examination by the officiating doctor and be pronounced physically sound.

"The company reserves the right to discharge without notice, while the employee who desires to quit is required to give notice in some instances as long as three months in advance. Failure to comply with this regulation invariably results in forfeiture of bond, and, as one of our German brothers put it, 'every strike is a breach of contract and if the men lose they forfeit their bond money.'

"An example of this is shown in the report on the strike of the tramway men of Saarbrucken, which occurred in 1911. It was conducted by a union not affiliated with the regular movement. The strike failed, and every striker reinstated had to pay the company 50 marks ($12) from his deposit money. The security was then increased 50 marks, so that each had to put up another 50 marks to make the deposit 100 marks ($24). The men who refused to return to work were fined by the company 92.50 marks, which practically confiscated the amount they had on deposit.

"All concerns furnish uniforms for the men, but these uniforms are furnished just as a shovel or any other tool is furnished. They are not the property of the men at all. They are simply worn while in the service, are kept in repair, and when the men leave the service they must be turned back to the company, or else they must be paid for out of the indemnity which the employee deposits on entering the service."

The report, in comparing the wages in 192 German cities, on both municipally and privately owned systems, says that the average wage for motormen during the first ten years of service varies from 73.5 marks ($17.64) to 147 marks ($35.28) per month. During the first five years of employment there are fifty-six concerns that pay from 73 to 90 marks ($17.52 to $21.60) and 124 that pay from 90 to 105 marks ($21.60 to $25.20). Some of the wage scales call for fifteen, twenty and thirty years of service and even more before the maximum pay is reached. The conductors usually get about $3 a month less than the motormen.

This difference they are supposed to make up in tips they receive from the riding public.

FRANCE

There is no municipal tramway development in France. In Paris there are some 24,000 men employed in the tramway, underground and omnibus systems; 10,000 on the trams or surface railways, 5000 on the underground, and 9000 on the omnibus service. Of these the tramway and underground men have responded least to organization.

The systems of wage on the transportation lines of Paris differ. Some employees are paid by the month, some by the day, and others by the hour. In the train service there are five grades of pay. In the fifth class men receive 165 francs ($33) a month; fourth class, 175 francs ($35) a month; third class, 185 francs ($37) a month; second class, 195 francs ($39) a month, and first class, 200 francs ($40) a month. The entrance to these various classes is not fixed by time service, but depends upon vacancies in each, so that promotion from a lower to a higher class, with resultant increased pay, can come only when a vacancy occurs. The workday on the Paris trams is ten hours, and most of the runs are completed within twelve hours. The law provides one day off in seven.

SWITZERLAND

There are forty-one tramway systems in Switzerland, eight of which are operated by municipalities and thirty-three by private concerns. The total number of all tram employees in Switzerland is 3553, including all classes. The right of the workers to organize is guaranteed by law. The laws of Switzerland also provide for insurance against sickness and accident. The managements are compelled to insure all employees and pay all premiums.

The wage at Berne for conductors starts at 150 francs a month, or $30, and reaches 220 francs a month, or $44, in ten years. The beginning wage for motormen is 155 francs a month, or $31, and after ten years the maximum is 230 francs, or $46 a month. The workday is nine to ten hours, completed in fourteen to fifteen hours. Berne has a municipal line. On the privately operated trams in Switzerland, the wage paid employees is a trifle less than on the municipal roads.

ITALY

The investigation of the conditions in Italy was interrupted by the outbreak of the war. Some figures, however, were obtained in Rome and Milan. In Rome there are one steam and four electric tram lines. One of these is owned by the municipality, which will take them all over in 1920. The wages on the private lines begins at 64 cents a day, and the maximum wage after ten years' service is 94 cents a day. The workday is nine hours, completed in about thirteen hours.

The wage on the municipal road is 10 cents a day more than on the privately owned roads, but other conditions are about the same. On the municipal system the employees are paid every two weeks, and on the private systems they are paid every week. Trainmen on all roads have one free day in every fifteen.

GREAT BRITAIN

Two cities only in Great Britain were investigated, London and Glasgow. The wages for the motormen and conductors on the lines of the London County Council Tramways is from $1.20 to $1.56 per day. These wages are higher than on the privately owned lines in or about London, but the latter are all outside the County area and in less congested districts. The workday is nine to ten hours, completed in fifteen, and the six-day week prevails.

In Glasgow the employees in the various mechanical departments of the municipal tramways to the number of about 400 are organized, but the motormen and conductors, who number 3012, have no union. One was organized in 1911, but disbanded after a strike. The men work a six-day week of fifty-one hours. The wages per week for motormen and conductors vary from $6.48 for the first year to $8.16 for the seventh year and $8.40 thereafter. The physical tests required are very rigid and more exacting than for military service.

CONCLUSIONS

The conclusions in full follow:

"We began our investigation of conditions surrounding the tramway workers of Europe with an open mind. We were ready for impressions and determined to report facts as we found them. The war prevented us from going into the investigation as thoroughly as we had planned, yet the field that we covered and the access we had to information gave us a good understanding of conditions.

"The tram systems of Europe are not to be compared to the street railway systems of the United States. Throughout continental Europe and the United Kingdom, in the most thickly populated centers, the street railway service is inferior to ours in many respects. In the continental cities the track mileage is small compared with the United States. This contributes to density of traffic and profitable operation. The same is true of the United Kingdom, whose total street railway trackage is about 3600 miles as against 40,470 miles operated in the United States.

"We found the same spirit of commercialism dominating the electric railway systems of Europe, private and municipal, as exists in this country. If any credit is to be given either, it belongs, in our opinion, on this side of the water, for the American system, to our minds, is not only cheaper to the public, all things considered, but the service is better with a great deal more of it. Cheap fares on the zone system prove dear fares to the worker if he has to ride any considerable distance or take intersecting lines, for each zone entered means an additional fare, and there are no transfers on European systems. Zone fares and inadequate wages force the workers of Europe to live close to the workshop, mill or factory. It is rare to find a European worker who can afford to live in suburb or country, miles away from his work, as is frequently the case here. The rate of fare for long distance makes it prohibitive, and the wage will not warrant the expenditure.

"Thus the zone fare system contributes to congestion and compels the workers to live in the most uninviting districts. It retards suburban development and adds to the rents of the workers, who not only have to suffer the inconvenience of small living quarters but are denied sunlight and sanitary surroundings as well.

"And right here we desire to comment that with all the claim for legislative enactments helpful to the workers, municipal utility enterprise and co-operative development, we found the living standards of the workers of Europe, tram as well as others, so far below the average of the workers of America that no comparison is possible. The rapidity with which the workers of Europe are grasping the truth that their efforts must be concentrated in the economic field, through their trade unions, was the most hopeful sign that this condition would be altered.

"None of the European systems has a night car service, such as we have in our big cities. Nor have they an interurban electric service, that has contributed so much to the development of our rural districts and brought the consumer and producer into close relationship.

"Nor can there be any comparison between the wage of the European tram employee and his brother in the United States. From the viewpoint of the purchasing power of a dollar it has been estimated by careful observers that the cost of living in various parts of the United States is 25 per cent to 65 per cent higher than it is in various parts of western Europe. The difference in the money wage of the street railway men of these countries is much greater. The highest wage paid any body of tramway workers in Europe is safely 100 per cent less than the rate paid in this country in the same occupation, and we found this to be the fact both on private and municipal systems.

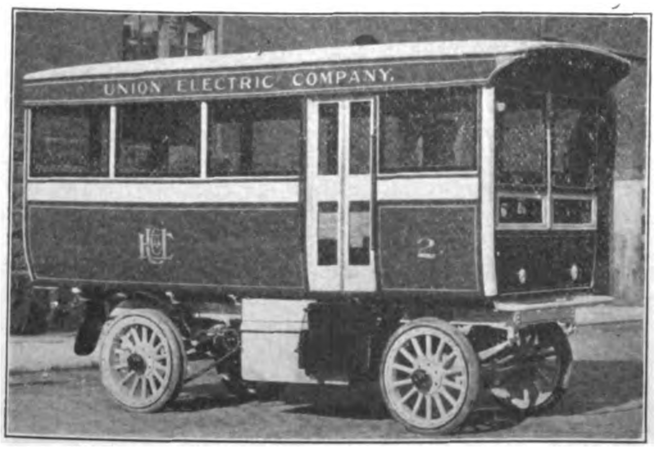
"Our investigation showed that wherever the tram workers of Europe enjoyed advanced wage and labor conditions their trade unions were responsible for them. Where the trade unions are active there the best results obtain, and whether dealing with a municipality or a private company the employees have found it necessary to maintain their unions to establish and protect their conditions."

After the above report had been presented and accepted it was returned to the writers for further consideration.

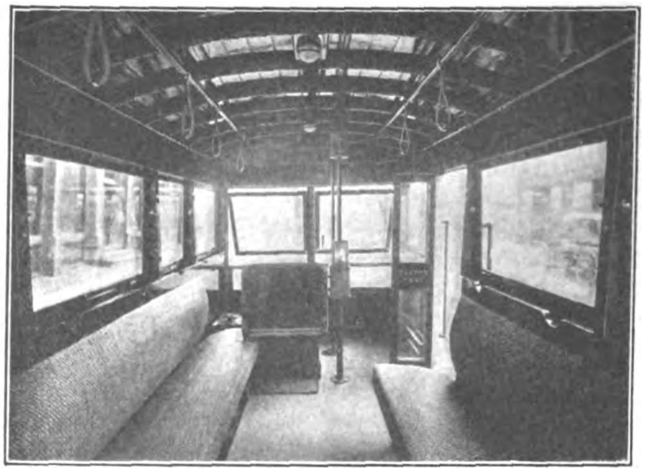
Electric Bus Service at Dubuque, Ia.

This Bus Line Connects with Four Divisions of the Union Electric Company's Car System

The Union Electric Company, Dubuque, Ia., placed in service during September, 1914, two electric buses of the type illustrated for regular service between Dubuque, Ia., and East Dubuque, Ill. This service was instituted in response to a demand of long standing from the residents of East Dubuque for a regular and dependable means of transportation between the two cities, East Dubuque being practically a suburb of Dubuque and having a population of 1500. A highway bridge owned by a private corporation and operated as a toll bridge connects the two cities. The city of East Dubuque granted the company a ten-year franchise for the operation of these buses and this was in due course approved by the Public Utilities Commission. Coincident with the granting of the franchise the Dubuque Bridge Company made a contract giving the railway company the exclusive right to operate a bus line over the bridge.



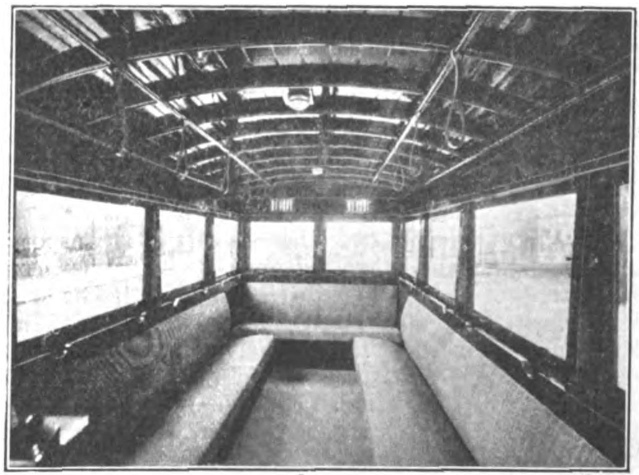
DUBUQUE ELECTRIC BUS SERVICE—VIEW OF BUS, SHOWING STEPS FOLDED AND DOORS CLOSED



DUBUQUE ELECTRIC BUS SERVICE—INTERIOR OF PASSAGEWAY, SHOWING ALSO LARGE SASH

A 5-cent fare which includes a bridge toll is charged each way, except that children under six years of age are carried free. The distance traveled in a round trip is slightly more than 3 miles. The Dubuque terminus of the buses connects with the Union Electric Company's street car system at a convenient point, making direct connections with four of its five divisions.

The bus bodies were built by H. McFarlane & Company, Chicago, and are mounted on 2-ton underframes built by General Vehicle Company. They seat twenty passengers. The buses are very sightly and their painting conforms to the standard used by the Union Electric Company in painting all of its cars, namely, special traction orange, lemon, with Tuscan red trimming and silver striping. The buses are equipped with Edison batteries. While one bus is in operation the other is receiving a fresh charge.



DUBUQUE ELECTRIC BUS SERVICE—INTERIOR OF BUS AT THE REAR

E. M. Walker, general manager, advises that so far the service has been carried on without mishap and has given the very best satisfaction to the people, besides having received the enthusiastic support of the press. No transfers are given from the buses to the street cars, the fare being 5 cents straight.

The council of the Society for the Promotion of Engineering Education has decided to hold the 1915 meeting of the society at the Iowa State College, Ames, Ia., on June 22 to 25. Dean Marston, of the Iowa State College, is president of the society.

Meeting of Railway Commissioners

Among the Subjects Discussed Were the Statistics and Accounts of Electric Railway Companies, the Present Status of the Valuation of Common Carriers, Rails and Equipment, and Service

The twenty-sixth annual convention of the National Association of Railway Commissioners was held in the rooms of the Interstate Commerce Commission, Washington, D. C., this week. The sessions began on Tuesday morning.

The address of welcome was delivered by Commissioner Clements, of the Interstate Commerce Commission, who called attention among other things to the confusion and embarrassment produced where different states adopt divergent and conflicting policies which become the basis of transportation rates.

In his annual address Commissioner Finn of Kentucky, president of the association, referred to the development of the principle of government regulation of common carriers which, he said, came into existence seventy-five years ago in Rhode Island to protect citizens against discrimination practiced by steamboat companies. Subsequently the policy was applied by other states to transportation by rail. Twenty-five years ago the federal government enacted legislation to compel common carriers to give adequate service at reasonable rates without discrimination.

Continuing Mr. Finn said that the accomplishments of governmental regulation justify the time, money and labor expended, and it is accurate to say that the discrimination between individuals has been almost abolished. The task of eliminating discrimination between localities is more difficult, and in this connection Mr. Finn discussed the long and short-haul provisions of the law. He then advocated regulation and control by the authority of the state and federal government and embracing every detail of the activities of common carriers, including investments, expenditures, equipment, material, construction, operation and charges.

On account of entangled alliances between transportation companies and other big business industries, common carriers, he said, have never had a fair chance to demonstrate their maximum benefit to the public. While Mr. Finn did not specifically advocate government ownership, he made several statements which indicated a leaning in that direction. He held that an employee does not lose his efficiency when employed by the government, and that employees of private corporations are not more proficient than those engaged in government service. He said that economy demanded the elimination of competition between public service enterprises, and if private monopoly is indefensible and intolerable, he asked why a necessary monopoly should not be publicly owned.

The report of greatest interest to electric railway companies presented at the meeting was that of the committee on statistics and accounts of electric railways. An abstract of this report is published on page 1142. Abstracts of some of the other reports of interest to electric railway companies appear below.

RAILROAD TAXES AND PLANS FOR ASCERTAINING FAIR VALUATION OF RAILROAD PROPERTY

This report was submitted by Messrs. Eshleman, California; Maltbie, New York; Erickson, Wisconsin; Hemans, Michigan; Lewis, Washington; Henshaw, Oklahoma, and MacLeod, Massachusetts, and was devoted to a discussion of the methods and status of the valuation of railroads being undertaken by the Interstate Commerce Commission. In the matters discussed, the committee does not make any positive recommendations because it does not believe that these lie within its province, but said that the Interstate Commerce Commission has indicated a desire to consult with the Railway Commissioners' Association in this work, and the committee believes that the association program and work should keep in close touch with the valuation as it progresses.

The report urges, first, clear-cut definitions by the commission on such terms as "original cost to date," "cost of reproduction new" and "cost of reproduction less depreciation," as the commission and perhaps the courts will be called upon to fix the proper definition of these terms. This should not interfere, however, with the assembling of physical data.

After describing the present organization of the board of valuation engineers, the report discusses the different valuation orders and believes that "abandoned property" should not include property which is nonoperative unless it is necessarily held for operative purposes in the immediate future. It also says that while addition and betterment reports are not required for any railroad for which the government has not started the valuation work, all companies should keep their records of additions and betterments in such shape as to permit the ascertainment of such information desired as to unit cost.

In discussing depreciation, the report refers to the contention of many railroads that there is no such thing as depreciated value and that the present value of the physical property equals 100 per cent of the reproduction cost new. On this point it says that while the final determination as to the depreciated value of the carrier's property will not be left for the decision of the field parties, they should obtain the necessary information for its determination. The report also says that depreciation can be defined as the lessening of the value of the property from physical causes and that it has no relationship to the lessening of the value of property from economic causes which are not related and are unaffected by physical depreciation. The engineering and accounting aspects of depreciation are often confused. The former considers it as a condition at a given time of a piece of property as compared to new. The latter has to do with the setting up of a bookkeeping method for accumulating a certain fund. Rates should be imposed which as a system will return to the carrier the expenses for performing its service, give an earning upon the value of the property and return a sufficient amount so that when the property is worn out in the service of the public the carrier's capital shall have been returned to him.

The report suggests further instructions to the field parties in regard to certain matters, including the necessity of differentiating between seasoned and new roadbed, of obtaining data as to any expense of building contractors' roads during construction and of making notes on the condition of the property complete enough to make it possible to differentiate between functional depreciation, deferred natural depreciation and the depreciation which is normally taken care of by seasonal repairs and renewals. In regard to donated property the report recommends the inclusion in the "cost" figure of the cash equivalent of such property at the time of its receipt.

In conclusion, the report says that the accomplishment of the work proposed in the valuation statute is impossible in its entirety, but the difficulties in the plan will be developed as the work proceeds. The commission is not pessimistic as to the value of the proposed valuation, but believes that it will not meet the expectations of those who framed the statute.

STATISTICS AND ACCOUNTS

This report was submitted by Messrs. Meyer, Interstate Commerce Commission; Prentis, Virginia; Meyers, Interstate Commerce Commission, and Sturgis, Association of American Accounting Officers, and described briefly the important changes made by the interstate and state commissions during the past year in their accounting systems. Among other points mentioned, the report said that the Nebraska Commission had given considerable study to the subject of depreciation of telephone plant equipment and of street and interurban railway plant and electric railway equipment, that the Oregon commission had adopted a uniform classification of accounts for electric, gas and water utilities, and that the New Hampshire commission had adopted a uniform classification of accounts for electric utilities. It also explained and defended the order of the Interstate Commerce Commission requiring the steam railroads having operating revenues in excess of $1,000,000 per annum to separate their operating expenses between freight and passenger service. It also urged the state commissions to adopt the various accounting orders and system of accounts of the Interstate Commerce Commission, with necessary provision so that additional matters could be incorporated by the carriers in a supplement or appendix.

REPORT OF RAILWAY SERVICE AND RAILWAY ACCOUNTS

This report was submitted by Messrs. Hughes, Ohio; Mitchel, Louisiana, and Ott, West Virginia. Although devoted principally to steam railroads, it said that "The incidental handling of package freight with dispatch by electric railways and delays in handling l.c.l freight by steam lines opened the eyes of the public and electric line promoters to the wider field of general freight service, and such carriers have, as a rule, entered this field." The report urged better ventilation of passenger cars by the statement that "it is in reason to say more deaths are occasioned by improper ventilation of train coaches and waiting rooms than by train accidents." It also referred to the importance of good light and water supply on cars, neat maintenance of waiting stations, readiness to serve, courteous demeanor of agents, etc.

VALUATION OF COMMON CARRIERS

This report was signed by Messrs. Maltbie, New York; Atkinson, Missouri; Chandler, Georgia; Doty, Ohio; Erickson, Wisconsin; Eshleman, California, and Thorne, Iowa. It referred to conferences during the past year with representatives of the railroads in regard to different points which had come up in the matter of valuation and pointed out several ambiguities in the wording of the forms used in valuation work. One of these was the phrase "condition per cent" in many of the forms, and the phrase "depreciation per cent" in others. Both of these terms, the report said, are liable to differences in construction. The committee also made suggestions as to the method of handling inventories, abandoned property, land, etc., and defended the plan to ascertain the various sources of funds used in payment of existing property; namely (1) by the issue of securities, (2) from surplus income, and (3) from operating expenses. These data should be obtained irrespective of whether the differences will be considered in the final valuation.

RAILS AND EQUIPMENT

The report of the committee on rails and equipment was presented by Messrs. McChord, Interstate Commerce Commission; Paine, Indiana; Brecht, Pennsylvania; Woerner, Missouri; Spofford, Maine; Douglass, New York, and Boyle, Montana. After giving data on accidents, their relation to defective rails, character of defects, influence of loads, etc., the report made the following references to the "frictionless rail":

"A rail of modified shape of head, 'the Frictionless Rail,' so-called, has recently been put into service. The rail is intended for use on curves, the inside rail, for the purpose as explained of preventing the usual excessive thrust against the outside rail when a train passes around the curve. Rails of this type are in use in track of different degrees of curvature, ranging from 4½ deg. to 16½ deg., where they have been in service periods from one to three years. As described by F. A. Barbey, Boston, Mass.:
